THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 3, WASHINGTON-ST. ALBANY, N. Y. MAY, 1839. No. 3.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, D. LANDREITH, and M. S. POWELL, seedsmen, Philadelphia; ISRAEL POST, bookseller, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; HOVEY & Co. Merchants' Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

☞ Advertising. ☜

☞ At the request of many of our patrons, and to save the trouble of frequent inquiries, we propose to publish short advertisements in our last page, relating to farm stock, farm seeds, farm implements, &c. and to make up to our customers, at the end of the volume, by an extra sheet, the space occupied by advertisements. The terms of advertising will be one dollar for ten lines, or less, for each insertion, which will not be deemed extravagant for TWENTY THOUSAND impressions. Cash in advance.

The Debt of the Nation.

The *National Debt*, we believe, has been wholly paid off: but a new debt has since been created, by some of the states, of a greater amount than the national debt ever was According to the late Comptroller Flagg's tables, eighteen of the states have authorized a public stock, most of which has already been issued, and principally for canals, rail-roads and other internal improvements, of about *one hundred and seventy millions of dollars*, which is as much a mortgage upon our farms, as was the national debt. The interest upon this amount, which is ten or twelve millions annually, must be paid punctually, and the principal must be paid ultimately. And it is well to inquire, who owns this one hundred and seventy millions of stock? To whom are we paying ten millions of dollars annually as *interest?* Not, we are sorry to say, to members of our national family, but to foreigners—who are at least aliens to our country, if not secretly hostile to its institutions and its prosperity. Most of the one hundred and seventy millions of American stocks, have been sold in Europe, to pay mercantile balances, or to provide the means of making improvements, many of which, instead of repaying the outlay, are likely for a long time to continue to be a drain upon the treasuries of the states which have made or are making them. It verily appears to us, that some of the states, and our own state among the rest, have become deeply infected with the spirit of wild speculation, which so lately caused distress and individual ruin to many in our land, impaired public confidence, and deranged the ordinary course of business;—and that the states, like the individuals, will learn, when too late, that prudence is the better part of wisdom.

No individual can truly exercise the volition of a freeman, who is deeply involved in debt. He has not always the power of willing and determining according to the dictates of his conscience, or his sense of right. He is, though perhaps sometimes unconscious of it, more or less subservient to the will of his creditor; because he feels conscious that the creditor can harass and harm him. Hence, a man with limited means, who is under no pecuniary obligations, is more independent, if not more honest in his intercourse with society, than he who nominally possesses great wealth, but who holds a portion of that wealth on the sufferance of others. Prudent fathers admonish their sons, as a cardinal rule of life, *to keep out of debt.* It is true that individuals sometimes bolt into fortunes, by an adventurous speculation—but they do not always find, when successful, what they seek—a contented enjoyment of it. But we all know there are ten blanks to a prize in this lottery.

Wherein does the case of the nation differ from that of an individual? A nation is a community of individuals; and what would be prudent in the management of a family, would seem to be prudent and politic in the management of a state or nation. The head of a family often finds it necessary to repress the wild extravagance of the sons and daughters; and where he does not do it, bankruptcy is sometimes the penalty of indulgence. And the managers of a state should exercise a like prudence. If they give way to all the wild schemes of personal aggrandizement, however plausibly concealed under the guise of public improvement, which are pressed upon their consideration, in the hope of either winning power, or winning fame, we think they will betray a great want of prudence, if not a want of principle. The policy of a state *should* be that of a discreet individual—a liberal outlay upon all objects within its legitimate sphere of business—and which promise at least an ultimate interest upon the capital expended. No one would commend, in an individual, an expenditure which should not only *not* return him interest, but which should constitute a lien, and cause a perpetual tax upon his posterity. Feeling none of the fever of party, we conscientiously declare our belief, that millions have been already expended by the state of New-York, or the responsibility of payment assumed, from considerations unworthy the enlightened patriot, which will not, in the present age, pay an interest; but, on the contrary, will operate as an annual drain upon our treasury; and that if this system is followed up—call it either the wild speculation of enthusiasts, or the mad and reckless ambition of party—or the cool calculation of statesmen—the state will soon be in the condition of the foolish farmer, who, to gratify the weak and selfish views of his children, has incurred a greater debt than he can pay—and who must toil hard to pay the interest on the mortgage which covers his farm.—Economy is as commendable in a state as it is in an individual; and though at the present time it may be fashionable with neither, and may subject to ridicule its advocates, it is nevertheless one of the most sterling republican virtues, essential alike to individual and to national independence. It is the parent of plenty, of contentment, and of happiness. It is always most safe to err on the side of prudence, if we do err at all—for error here may be corrected, but it can seldom be on the side of extravagance. Every legislator, before he incurs a new debt, should bear in mind that the state is already pledged for forty millions of dollars, and that the mortgages for its payment are mostly in the hands of foreign capitalists.

Our statute books, for the last few years, bring forcibly to mind Æsop's fable of the dog in charge of the butcher's tray, who, unable to defend it from the avidity of other curs, said—"Well, then, I may as well have my share of the meat," and fell to accordingly, crying, "Here it goes! there it goes!"

We insert the following, as matters of useful record. The data have been collected and compiled by the late Comptroller. The rapid accumulation of debt within the last five years cannot but strike the reader with astonishment; and if it is considered that the state of N. York is already pledged, to the amount of twenty or thirty millions, beyond her present debt to complete internal improvements already authorized; and that some of these improvements are not likely, for a long time to come, if ever, to pay for repairs, attendance, and the interest on the capital loaned—we say, when these matters are duly considered, it will require no argument of ours to show, that we are hastening to a dangerous crisis. Such reckless extravagance in an individual would be branded, by common consent, as the highth of folly, and as highly demoralizing to society.

Statement showing the amount of stocks issued, and authorized by law to be issued, by the several states named below, in each period of five years, from 1820 to '35, and from 1835 to '38.

STATES.	1820 to 1825.	1825 to 1830.	1830 to 1835.	1835 to 1838.	Total.

* Of this amount about 4 1-2 millions of dollars has been redeemed. † Virginia has a war debt of $343,139.17, contracted previous to 1820. ‡ South-Carolina has a revolutionary debt of $193,770.12

The debts of the states have been created for the following objects, viz:

For banking,	$52,640,000
For canals,	60,201,551
For rail-roads,	42,871,084
For turnpikes and M'Adam roads,	6,618,958
For miscellaneous objects,	8,474,684
	$170,806,277

Root Culture.

V.—THE TURNIP.

The turnip culture, it has been remarked, effected as great and beneficial a revolution in British husbandry, as the introduction of the steam engine and spinning jenny effected in British manufactures. This crop has there proved a great source of wealth and fertility. It constitutes by far the greatest material for making beef and mutton, as well as for enriching, or keeping up, the fertility of the soil. From an experience of twenty years, in the culture and use of this root, we are persuaded it is destined to become the means of great improvement in American husbandry, when our farmers become more familiar with its culture and mode of preservation and feeding.

In the fourth number of our third volume, we gave particular directions for the cultivation of this root, with several illustrative cuts, and for preserving and feeding them to farm stock; and in our March number of the present volume, we have given an estimate of the product and value of the Swede, compared with other crops which we cultivate for feeding and fattening cattle. It would be superfluous, to repeat these details here, inasmuch as they may readily be referred to. Yet as we have many patrons who may not possess our third volume, we will give some brief directions.

The Swedish turnip, or ruta baga, has a manifest advantage over all other varieties of turnip, as cattle food, being the most nutritive in their properties, and retaining their soundness and richness much the longest. The common varieties, if drawn, as all turnips must be with us, become pithy, or spongy, before mid winter, and lose much of their value; while the Swede rather improves, by keeping, till February; and may be fed in a perfectly sound state till June. And it possesses one quality, not known, that we recollect, in any other root—that of increasing in nutricious matter with increase of size—the largest roots being specifically heaviest and richest.

The reverse of this happens with other roots, particularly with beets, those of medium, or diminutive size, being found to contain a much larger proportion of saccharine matter than very large ones. For table use, the early rock turnip may be sown in the garden, the common flat or green top for autumn and early winter, while the yellow Aberdeen should be chosen for late winter and spring use, being the best keeping variety, when the ruta baga is either not liked or not to be had.

All kinds of the turnip like a sandy and a dry soil; and the ruta baga, in particular, requires a rich one. We have been accustomed to raise the common varieties as a second crop, i. e. of sowing upon a grain stubble, with a single ploughing and harrowing, after the grain is harvested, from the 25th of July to the first of August, brushing or lightly harrowing in the seed. The plants must be thinned and cleaned with a hoe. They should not be left to stand nearer than six or eight inches. If sown broadcast, they yield more, and are of a more suitable size for the table than if raised in drills.

A grass ley is best for the Swede. If an old sod, it should be ploughed in autumn, or early in the spring; and it should be dunged and completely pulverised on the eve of being planted. If a young clover ley, the dung may be spread, ploughed under, the ground harrowed, and the seed immediately put in. We usually select the latter. We cut the clover by the 25th of June, and manure, plough and sow the crop within the ensuing seven days. The seed is generally sown with the drill-barrow, at the rate of a pound to two pounds an acre. It is preferable to sow thick, on account of the fly, and as the crop may be readily thinned when the plants are out of danger.

The turnip fly often commits great depredations upon the crop. This was particularly the case the last season. We cannot recommend any certain preventive. It has however been stated that mixing the seed with sulphur several days before it is to be sown, and then sowing the sulphur with the seed, has preserved the crop from the fly. If this is so, it is owing to the juices of the young plant becoming impregnated with the subtle properties of the sulphur, which is obnoxious to every species of insect. Another mode, which has been successfully tried, is that of collecting the weeds in piles around the field, when the seed is sown, and when the plants are coming up, to put brimstone and fire upon the piles on the windward border, which will continue burning, ordinarily, for some days, and the smoke of which expels or destroys the fly.

In the after culture of the Swede, there is great economy in taking time by the foretop—in destroying the weeds while they are small. The cultivator or hoe should be passed through as soon as the rows can be well discerned, and as nigh to the plants as possible. One days' work is worth more in destroying small weeds than four days work is in destroying large ones, which overtop and choke the plants. The objects which should be aimed at, are to keep the crop clean, to thin the plants to eight or ten inches, and to keep the surface of the soil mellow. With a timely use of the cultivator, and repeated once or twice, these objects may be effected without great aid from the hand hoe.

The labor of harvesting the ruta baga is less than that of any other root, except perhaps the mangold wurzel; and indeed the remark will apply to the labor of culture without any qualification. Other root crops require attention nearly two months longer than this does, and at a season too when their growth is slow, and the labor consequently tedious and expensive.

The turnip should be the last crop gathered, because it grows the longest, is least liable to suffer from frost, and is most apt to be injured by fermentation, when collected in heaps for winter. If buried in pits, the roots should be raised above the surface of the ground, and laid up to terminate in a ridge—so that when they are covered with straw and earth, the heated or impure air of the pit will concentrate at the ridge on the top, where it should be suffered to pass off freely, through holes made for this purpose.

The cost of raising the ruta baga is less than that of raising corn, or any of the other roots. The average product may be stated at 600 bushels, and it is often double this quantity. The root is an excellent food for every species of farm stock, and is very extensively used for fattening both beef and mutton. Milch cows fed with ruta baga should have daily access to salt; and should the milk retain any flavor of the turnip, it may be got rid of by turning a pint of hot water into a pail full when it is drawn from the cow. Tops that are undergoing fermentation, and roots that have partly decayed or are unsound, should be given only to hogs.

THE TURNIP FLEA,

Is one of the greatest scourges to British husbandry. The Farmers' Magazine contains a learned article upon this insect (*Haltria rumorium*) giving us its natural history, and containing an examination also of the various remedies which have been recommended to prevent its destructive ravages, embracing the applications of lime, sulphur, soot, urine, fumigation, &c. Although these remedies, or some of them, are admitted to have had partial success; yet none of them, in the opinion of the writer, Mathew M. Milburn, can be depended upon with any degree of certainty. He thinks Mr. Poppy's plan of protecting the Swede valuable, which is to drill between the rows the common turnip, which the flea seems to prefer to the Swede, and when the latter has acquired the rough leaf to plough up the common turnip—yet he concludes by saying, that if attention is paid to the following particulars, he thinks the crop may be generally saved.

"1. Hasten the germination of the seed by all natural means as applying some portion of stimulating manure, sowing when a proper degree of moisture exists, and in close connexion with the manure, to secure to it at once the benefit of it to the roots, if possible, making most of the season when favorable.

"2. Sow a liberal quantity of seed, never less than three pounds, and sow it in drills, which will hasten the vegetation after it has come up.

"3. Clear the land perfectly, that no weeds may spring up to impede the growth of the plants, and give the soil a liberal supply of manure suited to its character.

"4. As a preventive, rid the soil by hand weeding, horse hoeing, &c. as much as possible of weeds.

"5. Select good seed, and test it before sowing, to see how many germinate, and in how little time."

Schools of Agriculture.

Propositions for establishing schools of practical and scientific instruction in agriculture, have been before the legislatures of Ohio and Kentucky, and we believe of Maryland, during the last winter, with what success, we are at the time of writing this unadvised; and the subject has been agitated in other states. In New-York, we have an act of incorporation for the establishment of such a school, and we only lack the liberality, we may say the patriotism, to put it into speedy and successful operation.

We ask our citizens of wealth, who are willing and desirous to do something for the future prosperity of the state, and we know there are many of this description, to give this subject a few moments consideration; to reflect upon the bearings which schools of this kind may have upon the industrial, the moral, the political, and the social institutions of their country—upon themselves and their posterity; and to decide whether they can render a greater good towards promoting these great objects of national and individual happiness, than in aiding in the establishment of these schools. They have sons whom they wish to see established in honorable and independent circumstances. What situation more honorable, or more independent, than that of an intelligent cultivator of the soil? At the meeting of the American Institute in 1837, the remark was made to us by two elderly gentlemen, one from New-Jersey and another from Albany, and at different times, that twenty years ago, they were acquainted with almost every importing dry good merchant in the city of New-York, and that now there was not half a dozen of them alive and in good business! A moment's reflection will satisfy the experienced, that the mercantile business of our country is overstocked; that it is deceptive, hazardous and dependent—because its success must depend upon the good will, and often upon the honesty, of others, and sometimes upon contingencies that are prejudicial to the country. Will you send your sons to the learned professions? The avenues to these are already choked with votaries—and it is not the sons of wealth who generally distinguish themselves here—poverty and want—self-dependence—are the great stimulants here to industry and success. And to make your sons merely gentlemen—to consign them to idle habits, or to make them the miserable dependants of official patronage, is the greatest disservice you can render them. It is a truth which few will deny, that most of the men of capital and of influence of the present day, are those who have from necessity been brought up to habits of business, and who have risen by their personal exertions; while many of the sons of affluence, from a lack of good early habits, have degenerated in property, in usefulness, and in character.

Further—every man is interested, deeply interested, in the general character of the society around him. If this is bad—if his neighbors are idle and ignorant, they are consequently poor, and are apt to be vicious. If they are intelligent and industrious, they are wealthy and respectable. Hence the importance to all, of rendering labor intelligent and productive. And the character and welfare of the state depend emphatically upon the character and welfare of the agricultural population. They are decidedly the primary source of our wealth, and the conservators of our republican habits and institutions.

Agricultural schools constitute one of the most important improvements of the age. They are calculated to make men industrious and useful, who would otherwise be idle and useless—to make those moral who might otherwise be immoral. Their tendency will be to improve society in various ways, without any apparent drawback to the benefits they promise to confer. And however slow we may be to adopt them, they *will* be established, they *will* be popular, and *will* yet largely contribute to IMPROVE THE SOIL AND THE MIND—to increase our wealth—to render us more independent, individually and nationally, and to beget a more enlarged, liberal and tolerant spirit in our people and in the administration of government.

Do we desire to make our sons lawyers, doctors or merchants, we feel the importance of placing them under *good masters*, who will teach them the principles and the practice of their business. Yet in husbandry, which involves more science than any other pursuit, which exhibits all the gradations in practice from very good to very bad,—and which is the great business of the state,—we seem not to care *who* teaches our sons, *how* they are taught, or indeed whether they are taught at all.

Having been invited to give our opinion as to what would be a suitable provision for an agricultural school, and as to the manner of conducting such a school, we shall answer the inquiries by giving an abstract of the report made in 1833, to the New-York State Agricultural Society, on this subject, and by stating some of the prominent features of the act to incorporate the New-York State Agricultural School.

The report commences by stating, that the main objects of an agricultural school are, to impart to this great branch of labor the efficient aids of science, and to furnish it with the best models of practice;—to teach, simultaneously, in the period of academic life, the practical operations of husbandry, and such branches of useful knowledge, as may tend to increase its products, and elevate its character,—or, in other words, the *objects* may be defined to be—*to make the man*—THE WHOLE MAN—THE USEFUL MAN.

To effect these objects, the plan should embrace—

1. A farm of sufficient extent to afford room for the diversified operations of tillage, cattle and sheep husbandry, and of orcharding and gardening, on a scale that will admit of a fair comparison being made of crops, of breeds of cattle and sheep, and of the varieties of hardy fruits; and sufficiently diversified in soil and surface to admit of satisfactory experiments:
2. A farm-house and farm buildings, which may serve as models of convenience, taste and economy, and accommodate the head farmer and his assistants:
3. A school building, to accommodate teachers and pupils:
4. A library and philosophical apparatus:
5. Stock and implements for the farm: and,
6. Shops for the construction of farm implements and machinery for the use of the farm, for the illustration of mechanical science, and to afford practical instruction to the pupils in mechanics.

The plan of education might embrace—

1. Practical instructions in all the various operations and labors of the farm, the garden, the orchards and the shops; and,
2. The study of the natural sciences generally, chemistry, the higher branches of mathematics, mechanics and drawing, so far as they may conduce or become subservient to agricultural improvement—together with such other branches of knowledge as will qualify the pupils for the higher duties of life—such as will fit them to become independent electors, discreet jurors, faithful magistrates, and wise and honest legislators.

As prerequisites to admission to the school, the pupils might be required to possess a good common school education, to be at least fourteen years old, and of good moral character. Four years might constitute a course of studies to make good farmers in practice—and gentlemen in intellect and manners. The police of the school might, in a measure, be conformed to that of our military school.

A department of the farm should be set apart for experiments in husbandry, and the details and results of these experiments should be accurately registered. The garden and the orchard should contain all the good hardy fruits, and specimens of all hardy plants, that may be useful on the farm, in the arts, in commerce, or that are ornamental—in order that the relative value of different species and varieties may be determined, and their mode of culture, and process of curing, taught to the pupils—and the approved kinds furnished for public distribution.

To put the school into operation, there will be required a principal, professors, teachers, a steward, &c. for the school; a first rate farmer and assistants for the farm; machinists for the shops; and a practical and scientific gardener for the garden and orchard.

The preliminary expenses, for the purchase of a farm of 400 acres, erecting the buildings, providing the library, apparatus, stock, furniture, &c. was estimated at $57,550; the annual expense, for the first year, including salaries of officers and others, and boarding 200 pupils, at $23,400—making an aggregate of $80,950. The income of the school, including the products of the farm, and the tuition and board of 200 pupils, at $150 per annum, was estimated at $34,000—thus giving an excess over the estimated annual expenditure, of $10,600—and showing, after making a liberal allowance for contingencies, &c. that the income would amply suffice to maintain and improve the school and farm, and to pay an interest upon the capital invested. The committee considered one hundred thousand dollars a sum adequate to the establishment of an agricultural school upon a broad and liberal scale, that will insure great benefit to the country, and a reasonable income to the proprietors.

The law incorporating the New-York State Agricultural School, authorizes a capital of $100,000, with liberty to increase it to $200,000. It contemplates a farm of four to five hundred acres of land, with suitable buildings, &c. It limits the dividends of the shareholders to five per cent per annum; and, in order to secure an efficient education in the practice, as well as in the theory, it requires, that during the eight summer months, the teachers and pupils shall devote at least one-half of the time to the practical business of the farm, the garden, or the shop.

In Ohio, an excellent spirit has been manifested.—Two individuals, we are informed by our correspondent, have offered donations of $5,000 each, and a great many have offered less sums, towards establishing such a school. In Kentucky it is proposed to raise money by loan, to establish such a school.

We believe the public mind is becoming fully satisfied of the utility of agricultural schools, not only as an efficient means of improving our agriculture, but as a means of fitting for usefulness, and for high public duties, a great many young men who have the misfortune to be born rich, and who are therefore in danger of dying poor, for want of some *respectable* employment, and an early instruction in its duties. Men of all classes in society, to whom we have broached the subject, *speak* in high commendation of the project, and profess a desire to educate their sons in such an institution.—Our late worthy fellow-citizen, James Caldwell, got up a subscription, on the event of a disastrous fire, for the relief of his fellow sufferers, he being a large sufferer himself. On presenting it for signatures, all expressed great sympathy, and were sincerely *sorry* for the distress of their neighbors. "*Sorry!*" exclaimed the philanthropist—"*how* MUCH *are you sorry?* Although myself a sufferer, *I am sorry for them* FIVE HUNDRED DOLLARS. Now please to write down *how many dollars* you are sorry." We would apply this anecdote to our school. If all who WISH it success, would DO a little—or would express their good wishes in *dollars*, the work would go bravely and speedily on. One hundred individuals, by a liberal combined effort, would not only merit, but would command success.

"It is said," remarks the Rev. W. E. Channing, in his lecture upon self-culture, "that any considerable education lifts men above their work, makes them look with disgust on their trades as mean and low, makes drudgery intolerable. I reply, that a man becomes interested in labor, just in proportion as the mind works with the hands. An enlightened farmer, who understands agricultural chemistry, the laws of vegetation, the structure of plants, the properties of manures, the influence of climate, who looks intelligently on his work, and brings his knowledge to bear on exigencies, is a much more cheerful, as well as a more dignified laborer, than the peasant, whose mind is akin to the clod on which he treads, and whose whole life is the same unthinking, unimproving toil. But this is not all. Why is it, I ask, that we call manual labor low, that we associate it with the idea of meanness, and think that intelligent people must scorn it? The great reason is, that, in most countries, so few intelligent people have been engaged in it. Once let cultivated men plough, and dig, and follow the commonest labors, and ploughing, digging and trades will cease to be mean. *It is the man who determines the dignity of the occupation, not the occupation which measures the dignity of the man.* * * * A man in the field seems to have more chance of improvement in his work, than a man behind the counter, or a man driving the quill. It is the sign of a narrow mind to imagine, as many seem to do, that there is a repugnance between the plain, coarse exterior of a laborer, and mental culture, especially the more refining culture. The laborer, under his dust and sweat, carries the grand elements of humanity, and he may put forth his highest powers. I doubt not there is as genuine enthusiasm, in the contemplation of nature, and in the perusal of the works of genius, under a homespun garb as under finery."

A matter of deep interest to the West.

It appears from the report of the Commissioners of the Canal Fund, of the current year, that there has been a *falling off*, in the last three years, in the amount of wheat and flour brought to tide water through our canals, independent of that coming from other states and territories, of *thirty-two thousand five hundred and thirty-six tons*, equivalent to *one million two hundred and fifty thousand bushels of wheat!* i. e. the surplus crop of West New-York, was one and a quarter million bushels less in 1838, than it was in 1835.

Whence this great diminution of product? Not from there having been less sown in 1837 than there was in 1834—for it is believed that the quantity sown in 1837 was at least one-tenth, if not one-fifth, greater than in 1834. This was caused by a larger amount of land being brought under culture, as well as from the high demand for this staple product. The deficiency was not owing to bad culture—for the culture, it is believed, has been gradually improving; nor to a bad season—that of 1838 being at least equal to those of ordinary occurrence; and although *a* grain worm, long known there, committed partial depredations, *the* grain worm which has for some years been the scourge of the east, does not seem to have reached our western borders.—The cause of the decrease is the same that has been operating, time out of mind, in the old settled districts of our country, and which has been travelling west—it is BAD HUSBANDRY—that *skinning system,* which takes all from the soil, and returns to it nothing.

We have often adverted to the fact, that wheat was once the great staple of East New-York; and that the district of country which formerly supplied our commercial capital with wheat and flour, extending one hundred miles north and west of Albany, does not now grow enough for its own consumption. The remark will apply with more or less truth to most of the old settled country east of the Allegany range of mountains.—Wheat is very much like our improved Short-Horn cattle;—it pays well under good treatment, but soon fails from lack of proper food. It is the first crop to betray bad husbandry—that indicates a deterioration of soil. A great portion of the Atlantic border was once as prolific in wheat, and as greatly extolled for its fertility, as the now famed west. But our ancestors followed up the exclusive *plough, pasture* and *meadow* system—made annual drafts upon the riches of the soil, without making deposites to meet them—till neither wheat, nor hardly any thing else valuable, would requite them for their labor. The same inconsiderate course, we fear, is fast exhausting the fertility of the west. Wheat being the most valuable product, it is repeated at intervals of one or two years, and often every year, till the soil, like a worn down ox, can do them no further service. Whereas, were the soil kindly dealt by—were wheat returned to it not oftener than once in four or five years—were manures faithfully applied, and suitable crops alternated—it would, like the well kept animal, improve with use, and be a blessing to coming generations. Wheat is one of the most exhausting crops that is cultivated upon the farm; it requires specific food, of which most soils possess but a small portion; and although it has been grown in successive years upon some, there are very few old cultivated lands which will give an undiminished crop, oftener than once in four or five years, under a good system of husbandry. The remark has been made to us by several gentlemen, that in the last few years, the product in wheat, at the west, has not been any thing like what was expected from the strength and appearance of the straw. In all primitive formations, great *straw* may be grown by making the land rich with dung; but the wheat, the good wheat, will be found lacking.

We will here again allude to a fact communicated to us by T. Burrall, Esq. Mr. B. manages an excellent wheat farm in the vicinity of Geneva; he has made and applied much manure, and is, withal, a very observing and intelligent agriculturist. He kept an accurate account of his wheat crops for twenty-one years after he began to clear up his farm. Dividing the twenty-one years into three equal periods, he told us that the average product of the first period was twenty-nine bushels of wheat the acre—of the second period twenty-five bushels, and of the third period but twenty bushels.—Mr. Burrall's error was probably the common one, that of recurring too often to the wheat crop. But this case will serve in a measure to explain the cause of the falling off of the wheat crop in West New-York, a million and a quarter of bushels, in the short period of three years.

The prospect before us, in regard to this great staple of our state, would be disheartening, but for the consideration, that we *can* do better than we have done—and for the determination, which we hear expressed on every side, that we *will* do better. We have seen, in our day, many farms and even districts, which would not grow wheat, and which were reduced to the verge of barrenness, so renovated and enriched, by the improved husbandry, as to yield, at proper intervals, crops of twenty, and thirty, and sometimes forty bushels of wheat to the acre, and other products in proportion. What *has* been done, *can* be done again, and *must* be done, even in the west, unless our western brethren will profit by our errors—and act upon the principle, that it is better to *preserve* than it is to *restore* fertility.

The fault of the western farmer, and it *was* the fault of the eastern farmer, is precisely that of the youth born to fortune. He finds himself surrounded, and he stops not to inquire either *how,* or for *what purpose*—with the means of gratifying his grosser appetites—his eating, drinking, idle and avaricious propensities—with a rich and fertile soil—and he dashes on to the gratification of these appetites, unmindful alike of his ultimate interest, and of his duty to posterity. Wheat! wheat!! wheat!!! is the grand desideratum—we may say his almost entire reliance, for wealth and happiness. Like the foolish shepherd, who endangers the life of his flock, by taking from them two clips in a season; or like the silk culturist, who would kill the tree to feed a second crop of silk worms—the western wheat farmer forgets that nature has her laws, which cannot be violated with impunity—and that a violation of them will lead alike to the death of the animal and the plant, and the impoverishment of the soil. So completely infatuated have most of the wheat farmers been, in all periods of the history of our country, with the prospects of present gain, that they have neglected, till impelled by necessity, those considerations of prudence and foresight, which must ever serve as the grand land-marks of good husbandry. What credit is due to the son of wealth who wastes and spends his paternal inheritance? What credit is due to the farmer, who exhausts the fertility of the soil—nature's patrimony to the human family—to subserve temporary gain? Moral turpitude attaches alike to both. They both pervert the manifest intentions of a beneficent Providence.

We have travelled in some of the wheat districts of the west, and we have noticed, with painful sensations, the general disregard there to the maxims of good husbandry. Man seems to be improvident in proportion as nature has been bountiful—to develop his foresight, his skill and his industry less, where he has the ten talents, than where only one talent has been given to him. With, to be sure, many honorable exceptions, little attention is paid, in the wheat districts, to alternate husbandry, to the rearing of cattle, and to the economy of manures—the true sources not only of agricultural wealth, but the only sure means of perpetuating the fertility of the soil.

We invite our readers of the now fertile west, to take a retrospective survey of the history of the land of their fathers—of the once fertile east—and of the east, too, which is itself now profiting from its past experience and past errors—to mark the progress of its soil in deterioration, and the causes of this deterioration—the errors of their fathers in the management of its soil—and to act upon the trite maxim—that "an ounce of prevention is worth a pound of cure." They *have* a rich soil, which, like the princely estate, may soon be wasted by extravagance and folly. Let them use it—let them preserve it—let them live upon the interest, without impairing the principal. Then may they truly say—*we are wiser than were our fathers.*

It is a good rule, and one that ought to prevail where local circumstances will permit, that manure enough shall be made by the farm stock, from the straw, stalks, hay, and other resources of the farm, to manure one-fourth of it annually. After a few years' culture of new lands, good arable crops cannot be calculated upon without manure. If we should see an occupant of a Dutchess county farm, which has been brought to a high state of fertility by a good system of husbandry, cropping his grounds continually, without applying manures or alternating with grass—until they were exhausted of fertility—we should think him a bad farmer, and many would consider him a bad man. And yet wherein would his case differ from the reckless farmer upon new rich lands. The fertility, in one case, is the gift of Providence; in the other, it has been restored by the prudent industry of man: in both cases it is annihilated by his selfishness or his folly, and in both cases are the community alike sufferers.

The late Gen. Humphreys, of Connecticut, speaking of the improvements in agriculture, which have stood the test of practical and scientific investigation, enumerates the following, which we beg to commend to the notice of all, whether on new or old land, who would "*thrive by the plough.*"

> "1. The system of farm-yard manure, wherein every decomposable matter, animal and vegetable, is stored, to be used on the fields in regular succession.
>
> "2. The modern practice of using all manures as recently as possible. It is now well understood, that plants are nourished by the gases and juices formed during the gradual decomposition of manure, all which are lost in the old plan," of summer yarding.
>
> "3. The practice of farm-yard feeding, and sheep-folding, connected with the turnip husbandry.
>
> "4. In the substitution of fallow crops for fallows. It is true that fields are sometimes so foul with weeds that a fallow is necessary. In England, where a farmer is compelled to fallow a field, he lets the weeds grow into blossom, and then turns them down: in America, a fallow means a field where the produce is a crop of weeds *running to seed,* instead of a crop of grain.
>
> "5. In the more spirited husbandry of turnips and potatoes [and beets,] for feeding cattle, and of carrots in sandy lands.
>
> "6. In never permitting two grain crops to succeed each other. A fallow crop (that is, a horse hoed crop,) or a grass crop, always intervenes.
>
> "7. In selecting for pastures and meadows, those nutritive grasses that do not destroy each other, and that spring up at the same season.
>
> "8. In the great attention paid to agricultural machinery: to thrashing mills, to chaff-cutters, to drills and drill ploughs, to scarifiers, &c.
>
> "9. In cultivating plants of obvious profit, as madder, weld, [woad,] &c."

We will only add, that when Gen. Humphreys wrote, 1812 or 1814, the improved system of draining was not practised, nor had the culture of the Swedish turnip, mangold wurzel, or sugar beet been introduced.

The Privileged Classes.

We have, in the United States, say the journals of the day, eighty-eight colleges, twelve law schools, ninety-six medical seminaries, thirty divinity schools, and somewhere about one thousand academies, more or less sustained by legislative bounty, for the almost exclusive benefit of the learned professions, which do not comprise, probably, one-twentieth part of our population. We have not a single college, seminary or school, for the particular improvement of the other 19-20ths of our population—the farmers and mechanics—who earn our wealth, pay our taxes, and fight our battles—although,—we speak it in the spirit of truth,—the country would be more benefitted, in its wealth, in its morals, and in its politics—far more benefitted—by extending to the laboring classes a higher standard of learning, in what especially concerns their business, than it is from the aid which it now gives to the non producing classes. It is a republican maxim, that all should participate alike in the public bounty. But the maxim has not as yet been adopted by our legislators.

It is not too late to plant Trees,

About the dwelling, or upon the farm. "The shade of trees is highly grateful to man, whether reposing under a single tree, or in a state of recreation under the shadow of a row, or in an avenue, grove or woodland path."—*Loudon.* "Shelter is not more useful in cold seasons, than the shade of trees is gratifying to cattle in hot ones. In an exposed open field, and under a burning sun, the torture which cattle often endure, is truly distressing."—*Lang.* "In a country so eminently favored as this, by the vast number of the beautiful and magnificent varieties of trees which embellish our forests, compared to those which are indigenous to Europe, it is not a little surprising, that a deeper interest has not been developed, for rendering them tributary to the health, comfort and pleasure of the people, by considering them as indispensable to the completeness of a country residence, and the public edifices, squares, grounds, and highways, as are any of the appendages which are deemed useful, ornamental or agreeable in either."—*Gen. Dearborn.* There is no man, who planted a single tree in his youth, which lives and thrives, but looks back to that act of his youth with pride and self-gratulation; and there is hardly one such that does not regret that he had not planted more.

Moisture, Air and Heat,

Are all indispensable to the germination of the seed, and to the preparation, in the soil, of the vegetable food; and, with the further aid of light, are alike indispensable to the growth and maturity of the plant. A great object of tillage, and of keeping the surface mellow in hoed crops, is to admit these agents freely into the soil. Organic or animal matter may remain insoluble for years, when buried in the soil, and deprived of one of these agents; and seeds may lay dormant for centuries, it is believed, when deprived of their agency. Hence the first rule in ploughing is to expose the greatest surface to atmospheric influence; and this is done, not by laying the furrow-slice flat, when only the upper surface is exposed, say ten inches, if the furrow is so broad, but by lapping the furrows on to each other, by which more than twenty inches are exposed to atmospheric influence; with this further advantage, that with the flat furrow, an excess of water stands upon and injures the soil, while every lapped furrow-slice forms a conduit for passing it off.

"Teaching by Example."

C. Harbin, Esq. writes us from Mocksville, N. C. March 14, as follows:

> "I am much pleased with the private letter published in the February number, from your Hartford correspondent, and think that much can and ought to be done in the way he suggests, by those who feel interested in the great work of agricultural improvement. I met with the same difficulty in recommending the reading of agricultural periodicals to a certain class of our farmers, who, although industrious, hard-working men, and possessing some degree of general intelligence, reject every thing in the shape of book-farming, and hang on to the good old way, as they call it. Such prejudices can only be removed by the perseverance and industry of those around such men, by a frequent interchange of opinions with them, and occasionally reading to them such articles as may be most likely to make a favorable impression, and as fast as possible induce them to take an agricultural paper; because whenever a man will begin to read, I think his prejudices will begin to totter, and finally fall to the ground. You may set me down as a gratuitous agent for your paper at this place, and I hope to reap my reward for the interest I have taken in the work, in seeing a gradual improvement among the farmers of my neighborhood. The mind must be very dark that rejects the whole of the light thrown out through the columns of the Cultivator, and the other periodicals now published upon the subject of agriculture; and I think that by continually knocking at the door, some light will finally enter, and ere long the whole become lighted up. *Enclosed is your subscription paper, upon which you will find forty-seven names!* for the sixth volume."

Cedar Quarries.

On asking a friend from Oswego, the other day, who used this term, what it meant, he informed us, that much of the cedar which comes from Lake Ontario, is absolutely *dug out of the soil.* On some of the islands in that lake, which furnish great quantities of this valuable timber, there has not been growing a single tree for many years. Generation has apparently succeeded generation of this timber, and fallen, and been successively covered with earth, and is now *dug* out for rail-roads, fence-posts, &c. in a perfectly sound state.

American Society for the Diffusion of Useful Knowledge.

We conclude, to-day, the answer of the Executive Committee of the American Society for the Diffusion of Useful Knowledge, to the charges brought against it by our New-Hampshire correspondent. We do not wish to be considered either a party or an umpire, in the controversy, and shall therefore leave our readers to draw their own conclusions. We objected to the library which the society had got up for common schools, not so much on account of its demerits, as from its deficiency in works of intrinsic value to an agricultural population. And we furthermore doubted the competency of exclusively literary, professional and mercantile men, however good their intentions, to make a proper selection of books, suited to the wants, the tastes and the improvement of an agricultural population; for however intrinsically good books may be, they will do no good except they are read; and they will seldom be read when they are adapted neither to the tastes nor interests of those into whose hands they are placed. Few professional or mercantile men take an interest in reading works upon agriculture and rural economy. They, of course, are not competent judges of such works, and the society has, perhaps, acted wisely in omitting them altogether in their selection. The laboring community feel a like indifference to works of mere literature and taste. They would remark as an excellent farmer once did to us, when walking through our flower garden—"What are all these things good for? You can neither eat nor drink them, nor sell them for money." Men must acquire a taste for the flowers of literature, as well as for the flowers of nature, before they will admire or cultivate them. We must propitiate the husbandman, by teaching him how to increase the profits of his farm, before we can persuade him to devote his time to the embellishment of his garden. There is a natural gradation in these matters, and unless we begin right, with what is most likely to become useful as well as agreeable, we shall fail in our object. And as to the apology which is made for acknowledged deficiencies, while it may exonorate the managers from blame in the selection, it abates nothing of its faults. There was no obligation on the part of the society to get up a library, any more than there was in any other society, or individual. It was altogether a voluntary matter; and our regret, and we fear the public misfortune is, that it did volunteer, with the slender means, and precipitate hurry, which are urged in its excuse.

After attentively examining the defence, we are disposed to accord to the gentlemen managers of the society, an honest intention of doing a public service; yet we must question whether they have been successful to the extent which the name and character of the society led the public to expect.

One circumstance will not fail to excite surprise, and that is, that although we are furnished with the names of ninety-six officers, who have either positively or tacitly consented to bear the honors conferred upon them, to say nothing of the ordinary members of the society—we say, that notwithstanding the ninety-six officers—the wonder is, that only *twenty-five* individuals seem to have contributed any thing to the funds of the society! and that but *fourteen* of these have apparently contributed any thing more than the initiating fee!! We do not notice this to disparage the services of the few gentlemen who have devoted their means and their time to the professed philanthropic objects of the institution; but to mark the indifference which the American public manifest towards an institution which *might*, under proper encouragement and support, be of invaluable service to our country. It is a problem which remains to be solved, whether under existing circumstances, it will be easier to *mend* the old, or to *make* a new society.

We have been inadvertently drawn into the discussion of this matter, from a desire to fulfil a duty to our agricultural patrons. It has taken a turn which we did not anticipate, foreign to the objects of our paper. We have published the charges and the defence, and must decline any further notice of the controversy.

Mr. Weld's Manual Labor Report.

This report, drawn up by Thos. D. Weld, agent for the Society for promoting Manual Labor in Literary Institutions, contains a number of interesting facts and testimonies on the subject of manual labor, *when applied to literary institutions;* not as affording instruction in the business which the pupil is to follow for a livelihood—for life—but as a means of promoting physical health, moral health—and as having a salutary influence in developing the powers of the mind. In this case, it will be seen, the physical and mental powers do not act reciprocally. The mind is benefitted by the manual labor of the body; but it does not give back, to productive labor, aught that can simplify its operations, increase its profits, elevate its character, or multiply its enjoyments—because the object of the pupil is, not to learn to live *by* labor, in the common sense of the term, but to live *without* labor—to gain health and vigor of intellect, without gaining a knowledge of the arts of labor, with the view of making them the pursuit of life.

We beg the reader to bear these facts in mind, while he reads the extracts which follow; and to consider, with how much greater force they would apply in a school of theoretical and practical agriculture—where the study and labor would not only be directed to a common point—to the intended business of the pupil for life—but where study would instruct and lighten labor, and labor illustrate and enrich study. Theory and practice, in the learned professions—in the manufacturing and mechanic arts, are reciprocal aids, and agreeable companions. They call into action, when thus blended, our highest powers; they awaken the deepest interest; they excite the purest pleasures; they produce the most beneficial results. Who will say, that all these happy influences would not be realized in a school of agriculture, where the field of observation and improvement is illimitable, and where the object of study and of labor, is emphatically, to augment the happiness of the great human family? They *would* be realized. The experiment has been made, and has succeeded; and other countries, which, from political and contracted considerations, we are accustomed to consider below us in the scale of civilization, are reaping the benefits of these institutions; while we, who claim to be the most free and enlightened people upon the globe, are reposing in ignoble apathy—and striving, not who can, or will, do the most to promote the common weal—but who can do the most to promote his own interest, regardless of the common weal.

By the introduction of manual labor into literary schools, Mr. Weld contends:

"1. *The student would be kept busy.* In the present system, there are three or four hours in all our institutions, during which the student is set free from all requisitions. He has *nothing to do.* Then, if universal experience proves any thing, he stands upon slippery places. It was when the unclean spirit had found the house *empty*, that he introduced seven other spirits fouler than himself. Let any man visit our literary institutions, and take an inventory of facts upon this subject, and he will be convinced that hours of idleness are a gift to the student, originating in very questionable benevolence. In fine, modern education, by throwing into the hands of youth a number of vacant hours each day, *holds out a premium to insubordination*, and practically legalizes those innumerable devices of mischief, indecency, and outrage, which abound in our literary institutions. Instead of surrounding the forming character with bulwarks of defence, it opens a thousand avenues of access, and surrenders the individual to indiscriminate assault. Yea, more; it furnishes temptation with a passport to its victim, smooths the way for it, beckons it onward, and by refusing to make those requisitions which would keep it at bay, becomes its endorser, appears as its apologist and its advocate, and pleads for justification of the ruin it produces. Whereas, if this defect in the existing order of things should give place to a regulation which would fill up with suitable exercise those hours of idleness so perilous to the student, he would be kept 'out of harm's way.'

2. Sufficient exercise would be a preventive of moral evils *by supplying that demand for vivid sensation so characteristic of youth*, whose clamors for indulgence drive multitudes to licentious indulgence, or to ardent spirits, tobacco, and other unnatural stimulants. It would preserve the equilibrium of the system, moderate the inordinate demands of animal excitability, and quell the insurrection of appetite.

3. Sufficient exercise would operate as a preventive of moral evils, by removing those *causes* of irritability, jealousy, fickleness, and depression of spirits, which are found in an unhealthful state of the system. In corroboration of these views, permit me to introduce the following testimony.

'The most effectual security against external and internal causes of corruption, is *constant occupation*; and without this, *no system of discipline can be efficient.* * * * And it is especially important, while the character is yet unformed, and the appetites and passions yet unaccustomed to submission and self-denial.'—*Annals of Education.*

'Industry is the great moralizer of man. The *great art of education*, therefore, consists in knowing how to occupy *every moment in well directed and useful activity of the youthful powers.*'—*Fellenberg.*

'The declaration is as trite as it is true, that *exercise promotes virtue, and subdues the storms of passion.*'—*Dr. Harris of Philadelphia, on Physical Culture.*

'Labor of all kinds favors and facilitates the practice of virtue.'—*Dr. Rush.*

'Make men work, and you will make them honest.'—*John Howard.*

I. *The manual labor system furnishes exercise natural to man.*

That agricultural and mechanical employments are natural to man, is an obvious inference from the arrangements of Providence God designs that the human race generally should engage in these employments. He has placed men in circumstances which require it; and are those kinds of exercise for which infinite wisdom designed the human system, *ill adapted* to that system? Can human ingenuity devise an *artificial* system, better adapted to the necessities of man than that which God has prescribed?

'*Manual labor*, has in my opinion, decided advantages over *gymnastic exercises.* In addition to the superior moral influence which it is calculated to exert, the *kind* of exercise is better adapted to promote the healthy and vigorous action of the system.'—*Dr. Brown, late Physician to the N. Y. Hospital.*

'It appears, I think, from principle, as well as experience, that horticulture and agriculture are better fitted for the promotion of health and sound morals, than any other human occupation.'—*Dr. Caldwell, Professor Med. Depart., Transylvania University, Ky.*

II. *It furnishes exercise adapted to interest the mind.*

Agricultural exercise, and various mechanical employments interest the mind of the student,

1. By presenting a variety of objects to allure his attention.

2. By the successive changes effected in these objects *by his own efforts*, and the different forms which they continually assume under his hand, as the work goes on.

3. By the exercise of ingenuity, tact, and skill which they demand.

4. By the associating idea of their *usefulness*, not merely to himself, but to his country, and the whole family of man, in multiplying the comforts and conveniences of life; in promoting practical habits, and giving countenance to industry.

'No mode of exercise can in ordinary cases be compared, either as to profit or pleasure, with some kind of *efficient labor.*'—*Rev. Dr. Woods, Andover Theol. Sem.*

'If two or three hours ought to be spent in healthful exercise, why not employ those hours in the pleasant occupation of horticulture, agriculture, or mechanics.'—*Rev. Dr. Alexander, Princeton Theol. Sem.*

'I am equally convinced, that *manual labor* of some kind, is *peculiarly* adapted to this end,'—[for the purposes of exercise.]—*Professor Goodrich, Yale College.*

III. *Its moral effect would be peculiarly happy.*

IV. *It would furnish the student with important practical acquisitions.*

A practical acquaintance with agriculture and gardening, with some knowledge of mechanical employments, and skill in the use of tools, are accomplishments more than convenient to every man, whatever his station in life; accomplishments befitting the nature of our government, and the character of a republican people.

'Who would not wish for the capacity to help himself, on a thousand little occasions, at home and abroad, when a familiar acquaintance with the use of common mechanical implements, would enable him to avoid those many vexations which are wont to arise from the absence of mechanics, and their want of punctuality; which are so precisely suited to annoy the very persons, who take the least care to provide against them.'—*President Humphreys, St. John's College, Annapolis, Md.*

V. *It would promote habits of industry.*

Habit is formed by the repetition of single acts. To be constantly employed is to be forming a habit of industry.—*Constant occupation is the peculiarity of the manual labor system.*

VI. *It would promote independence of character.*

Exercise is the universal law of improvement for the faculties of the mind, as well as the powers of the body. If the memory is to be improved, it must be exercised. If scope is to be given to the imagination, stability to the judgment, and energy to the reasoning powers, the object can be accomplished only by the exercise of the several powers. Giving, enlarges benevolence; daring, increases courage; enduring, augments fortitude; and *self reliance promotes independence.*

Independence is an intelligent reliance upon one's own resources. If we would develop this principle, we must call it into action; and how shall it be called into action, except by creating a *necessity* for its action by throwing the individual upon his own resources; thus not only developing, but multiplying them? That system, then, by which the student can support himself with the least amount of aid from others, is manifestly better calculated than any other to promote independence of character. This, the manual labor system accomplishes.

When will a child learn to walk if it is never set upon its feet? He who bears all his weight upon others is in a fair way to become a cripple; and he must either lose his legs, or throw away his crutches.[*]

VII. *It would promote originality.*

The student who has been accustomed for years to tax his own resources for the supply of his wants, has formed a habit of inestimable value to his *mind.* Habituated to resort to himself for the means of his own support, he would be far more likely to construct his *intellectual* fabrics from the materials of his own producing. Instead of being a petty retailer of other men's wares, he would have a wholesale manufactory of his own. Let a demand be made upon such a man for thought, and instead of applying to his library for aid, and fumbling over every thing, from a commentary to a catechism, he will dig in the depths of his own mine, coin the metal in his own mint, and stamp it with his own image and superscription.

VIII. *It is adapted to render permanent all the manlier features of character.*

A system of seclusion, inactivity, idleness, and dependence, has a tendency to weaken the strong points of the character, and render it sickly and effeminate.

On the other hand, a system requiring activity, industry, exposure, energetic action, and self reliance, incorporates into the still forming character, the elements of firmness, decision, perseverance, courage, constancy, and generous self-sacrifice. It produces a commodity which the exigencies of our own age call for with deafening clamor, but which is a scarcity in the modern market—*manhood, full grown manhood.*[†]

IX. *It would afford facilities to the student in acquiring a knowledge of human nature.*

Whoever would understand human nature, must lay bare the springs of human action; the pulsations of the naked heart must be seen. The natural successions of thought and feeling must be marked as they come and go, and these lessons must be conned often and long, if he would be more than a mere smatterer in the science of human character. But how is the student to witness these exhibitions? Students generally are introduced into the higher classes of society, as they are called; and they will hardly get a glimpse at them there; where etiquette is law, actions are measured by rule, and the heart studiously covered up. The middling and lower classes of society, which are not wrapped up in the innumerable folds of ceremony, nor entangled in the endless meshes of fashionable forms, furnish the best text book in the science of the heart. But how shall the student narrow down the distance between the learned and the laboring classes, and thus get sufficiently near the latter to see them as they are? He may mingle with them a lifetime, but if he cannot make them *feel at home with him*, he can never see that unobstructed flow of thought and feeling which constitutes nature. He must first remove that instinctive aversion and prejudice which keep them from him; and these cannot be done away effectually, except by removing the causes which produce and perpetuate them; and the *main* cause is total dissimilarity in habits and mode of life. *Similarity of habits* strikes a common level, produces familiarity of intercourse, establishes a bond of union, and excites a feeling of mutual interest.

Let our students put on a working dress, and spend three hours a day in agricultural or mechanical employment, and they would disarm the laboring man of his prejudices, and beckon him toward them. That discontent, jealousy, envy, disgust, and those heart-burnings, which keep in a ferment the laboring classes in the vicinity of our higher seminaries, would give place to kindlier feelings. These classes would become approachable—a brotherhood would be established—and the student would enjoy a variety of facilities for acquiring a knowledge of men as they are, which would otherwise be denied him.

---

[*] "I cannot here omit particularly noticing, a quality of the manly character which our effeminate education is continually rendering more scarce. This is a certain wise confidence in our own powers, which prevents us from crying out for help, or falling into despair on every trifling occasion—a quality which must be at the bottom of every great or little enterprise, and which is indispensably necessary to enable us as men and citizens, to preserve a certain independence."—*Salzman.*

[†] "In a word, industrious habits of daily labor will metamorphose a book-worm into a *man*; a man prompt and ready for all emergencies.—*a man of the nineteenth century.*"—*Professor Staughton, Med. Col. Ohio.*

X. *It would greatly diminish the expense of education.*

XI. *It would increase the wealth of the country.*

Such a system would enable the sons of our farmers and mechanics, to acquire a thorough knowledge of those branches of science whose *practical application* to agricultural and the mechanic arts, would greatly increase both in quantity and quality the productions of the soil, and enhance the value of mechanical products. The benefits resulting to the *farming interest especially*, from a thorough acquaintance with the sciences of chemistry and geology, are little appreciated in comparison with their practical importance.

The system would increase the wealth of the country in another respect. In our academies, high schools, colleges, and professional seminaries, there are not far from thirty thousand youths. Let each of these fill up three hours a day with productive labor, and he makes no inconsiderable contribution to the resources of his country. He multiplies the means of subsistence, and augments the common stock of conveniences and comforts. These thirty thousand, by laboring three hours per day, would furnish an addition to the productive labor, and of course to the wealth of the country, equal to the labor of at least five thousand working men, who should labor ten hours per day. Besides this, the manual labor system would increase the wealth of tbe country, by contributing to its *health* and *muscle*, and no less to its *mind.*

XII. *It would tend to do away those absurd distinctions in society, which make the occupation of an individual the standard of his worth.*

Let the contents of our sixty colleges, and fifty professional seminaries, with a thousand academies and high schools, pour themselves into our fields and workshops, and there, for three hours each day, ply the implements of agriculture and the mechanic arts, would it not have a powerful tendency to render labor honorable, and the laboring man more respected?—Would it not create sympathies between the learned and the laboring classes, a permanent community of feeling, and identity of interests?

The thousand repulsions arising from dissimilarity of habits, which have so long operated to estrange them from each other, cease with the causes which produced them. Instead of being driven asunder by jealousies, and smothered animosities, they approach each other with looks of kindness, and form a compact, based upon republican equality, and the interchange of mutual offices of courtesy and kindness. He who does not perceive in such a system a tendency to these results, has mingled little with men; and however profound in other things, is a novice in human nature.

XIII. *It would have a tendency to render permanent our republican institutions.*

This would be the result of such a state of society, as has just been noticed. The elementary principles of republicanism are equality and reciprocity, its basis industry, economy, practical habits, general intelligence, and morality. We have seen that the connection of manual labor with study is calculated to produce these effects, and consequently to perpetuate our republican institutions."

A Compliment to our Correspondents.

The two hundred correspondents, who have given a value to the Cultivator, cannot but feel deservedly flattered by the following, which we quote from a letter, dated

"*Nashville, Tenn. March* 4.

"I have, independent of the $70 above, placed in the hands of Messrs. Trabene & West, 15 or 20 dollars, since they consented to become agents for the Cultivator. When the merit of the work was unknown in this section of country, I found it difficult to get an agent for the work; *but things have vastly altered.* I have no doubt, and I feel fully warranted in saying, that the circulation of the Cultivator, in middle Tennessee, has done more to improve our agriculture within the short space of eighteen months, than eighteen years would have done without it."

The compliment and invitation which are subjoined, by the writer, to the conductor, are very gratefully received, and the latter will be accepted, as soon as circumstances will permit.

A Comparison.

By comparing matters that are rather abstruse, with objects that are familiar with our senses, we often bring home to the understanding, truths of much practical benefit. The farmer who profits nothing from the better practice of his neighbor, but depends solely upon his personal experience, may be compared to the isolated spring, which bubbles from the earth always the same. The farmer of more enlarged mind, who sees and adopts the better practises of his neighborhood, may be likened to the brook, made up of the waters of several springs and which propels the water-wheel of the manufacturer. While the farmer who combines science with practice—who profits from all the improvements of our land, and of other lands, may be likened to the noble Hudson, which is fed from ten thousand fountains, and which bears upon its bosom the riches of every clime. Let those who consider the comparison bordering on the extravagant, contrast the powers and usefulness of a Fellenbergh or a Thaer, of a Chaptal or a Davy, of a Sinclair or a Coke, whose labors are adding millions annually to the products of the soil, to the drivelling ignoramus, who is delving in conceited ignorance, exhausting those riches of the soil, which Providence designed for his posterity.

The Corn Laws of Great Britain,

Are often spoken of in the public journals, without their object, or their operation at home or abroad, being generally understood by the American reader. The better to illustrate the matter, for it is a question which, if our agriculture ever reaches the state of improvement which it ought to reach, that may deeply concern Americans as well as Britons, it is proper to premise, that the farmers in Great Britain are not generally the proprietors of the land which they improve, but merely tenants to the nobility and gentry, who are the land owners. The rates of rent depend materially upon the ability of the farmer to pay; and this ability depends upon the price of grain in the market; the higher the price the better ordinarily for both landlord and tenant. Leases are given for different terms, often for twenty-one years; and if the improved condition of the farm and the price of grain will warrant it, the rents are raised at every renewal of the lease. To protect these two classes, or rather the first of them, or in other words, to secure a home demand, and a good price for the products of British husbandry, free from foreign competition, the corn laws impose a heavy duty upon foreign grain coming into British ports, so great as to amount to a prohibition, except in times of great scarcity, when the average price in market is sixty and seventy shillings the quarter of eight bushels. Were foreign grain admitted free, or by paying a nominal duty, prices would fall, and rents would have to come down, or the farmers be ruined. This explains the reason why the northern products of American agriculture are virtually excluded from British ports.

The continental powers of Europe have greatly increased the products of their agriculture, since the establishment of a general peace; and finding that these products will not be received on fair terms for British manufactures, they have been for some years turning their attention to the manufacture of their own goods. The consequence has been, that the demand for British merchandize has been constantly lessening in these countries, until the manufacturers, and a portion of the merchants, have become seriously cramped and alarmed; and meetings are now being held in all the manufacturing districts, to petition for a repeal of the corn laws.

On the one hand it is alleged, that if the corn laws are repeapled, and foreign corn admitted free of duty, English farmers, burthened as they are with heavy rents, tithes and taxes, can never sustain a foreign competition; that prices will consequently fall; that rents must come down; that the land holders and tenantry must consequently suffer severely; that the culture of poorer lands must be given up and abandoned; that the farm laborers, unable to obtain employment at prices by which they can live, will be reduced to want and misery; and that ultimately every class will be seriously injured.

The merchants and manufacturers, on the other hand, contend, that a reciprocity of trade can only secure the custom of foreign nations; that many of the manufactures have been stopped, the workmen thrown out of employ, and reduced to want; that the corn laws operate in favor of the land owner, at the expense of the merchant and manufacturer, the great supporters of British power, and the great sources of British wealth.

At our last dates matters were assuming a serious, if not an alarming aspect. Lord Melbourne, the premier, had declared in the House of Lords, that it would be the wildest and maddest scheme imaginable, to leave the agricultural interest unprotected; and in both houses, ministers oppose the repeal of the corn laws, and are supported by heavy majorities. In the mean time a radical convention was sitting in London, of which O'Connell and the Rev. Mr. Wade were active members. In reference to the determination of the government not to repeal the corn laws, and the strengthening of the military power of the throne, the convention recommend a rural police,—every man to go armed with a bludgeon, and to resist any attack on his person, &c. The Woburn, or Duke of Bedford's estate, is pointed out as among the spoils to be divided, if the landlords and capitalists, who are denounced, as "robbers, traitors and murderers," do not yield to the people—that they ought to be pursued by fire and sword, &c. All Yorkshire is said to be actually armed.

This state of things in England should admonish us, sedulously to protect our own resources, the agricultural and manufacturing labor of our country, and to avoid those enormous burthens upon agriculture, which there have become necessary, to pay the interest on an immense national debt, and to maintain, in idle extravagance, a privileged nobility, and a host of sinecure pensioners.

Wire Ropes.

It will be remembered, that many lives were lost during the last year, by the tiller-ropes of steam-boats being burnt off, when the boats have taken fire, thus leaving the boat and its passengers at the mercy of the stream and the fire, without the means of running the boat on shore. Samples of wire tiller-ropes for steam-boats, and also of wire tow-ropes for canal boats, have been left for examination at the Cultivator office, patented by J. McCord, of Harrisburgh, Pa. The tiller-ropes are already in extensive use in steam-boats on the Mississippi and Ohio; are three-eighths of an inch in diameter; have two strands of one hundred wires each, and, when submitted to a white heat, and cooled instantly in water, are as pliable as a hempen rope. The other sample is one-quarter of an inch in diameter, and has three strands, embracing one hundred and twenty wires. The larger kind is sold at twenty-eight cents, and the smaller at twenty cents per foot. We consider this a useful invention, calculated alike to economize expense and to preserve human life.

G. Farnham, No. 7 West-street, New-York, is agent for the patentee.

Items of Intelligence.

"Nothing," says Sir H. Davy, "is more wanted in agriculture, than experiments in which all the circumstances are minutely and scientifically detailed—this art will then advance in proportion as it becomes exact in its methods."

A Steam Threshing Mill has been put in operation in Switzerland. The machine is a five-horse power, and portable. It may be set at the barn-door. A few quarts of coal suffices for half a day. It requires but two men to tend it; and their work is equal to the labor of ten men with flails.

The state of Maine paid a bounty last year, of $87,352.39, on 1,107,849 bushels of wheat raised in that state; and $66,628.80, on 1,630,996 bushels of Indian corn—making an aggregate of $153,981, paid in one year, "to encourage agriculture."

THE BUDGET.

Under this head, we shall hereafter notice such correspondence as our limits will not permit us to give in detail, and such as requires to be noticed in a summary way. We have considerably increased the contents of our sheet, by the use of small type, yet our correspondence has been so enlarged as to compel us to condense some portion of it.

DWARF BLUE IMPERIAL PEA.

Joseph Kellogg, of Holland Patent, Oneida, a veteran of 72, has sent us an account of the field culture of a remarkable large blue garden pea, which he believes to be the dwarf blue imperial, and which he highly recommends. Mr. Kellogg received a handful of these peas in 1834, which were then selling at $6 per bushel; from this small beginning, he was enabled to raise, last year, twenty-four bushels of extraordinary beauty, and perfectly free from the bug. Mr. K. considers the pea as the best preparatory crop for wheat. In locations where the pea bug does not prevail, and on suitable soils—and clay loams and clays are the best—the field culture of garden peas, for seedsmen, may be made a lucrative concern. At present, most of the garden peas sold in the shops are imported, and sell at high prices.

APPLE ORCHARDS.

Philo Mix, of Waterbury, Conn. has sent us an interesting communication, recommending the attention of the young farmer to the cultivation of orchards, for farm stock and for family use. Mr. Mix remarks, that the old orchards in Connecticut have most of them died from old age, and that very little effort has been made for many years to replace them. Our correspondent seems to have been long familiar with the propagation, transplanting and management of fruit trees. He urges the importance of care in taking up trees, so as to preserve the fibrous roots—the mouths; and of making large holes to set the trees in, that the roots may have their natural position; of surrounding the roots with fine surface mould; of pressing the earth firmly round them, and of spreading upon the surface, around the tree, some litter or coarse dung, to counteract evaporation, to protect them from the cold of winter, and to prevent the growth of grass. Mr. Mix prefers autumn planting, and that the orchard be tilled two or three years, taking care, however, not to cut or bruise the roots or the stem in the operations of tillage. Mr. M.'s directions are all proper and beneficial.

REMEDY AGAINST THE BLACK ANT.

Joseph F. Plummer, of Richmond, Ia. sends us the following:—"Put half a tea-cup full of tanners oil—the more rancid the better—in a large dinner plate, or any vessel as shallow and broad, and set it on the floor of the closet, close the door, and in a day or two the ants will disappear. We have had them feasting in our sugar barrel, and by setting a plate on the sugar, with a cloth steeped in the oil, they soon left; and indeed I know of nothing more offensive to insects than the smell of this oil."

Mr. Plummer is informed, that there *is not* any agent in the United States, that we are advised of, for the importing of foreign cattle and horses; and that we receive subscriptions at all seasons.

SILK CULTURE IN POOR-HOUSES.

G. W. Forman, of Fleming county, Ky. asks—if it would not be a good plan to establish the silk culture in the poor-houses through the United States? We concur with him in the opinion that it would. We have urged the propriety of adopting this plan some years ago. And, to adapt the business more to the ability of the children and invalids of such establishments, we recommended that the mulberry be cultivated in hedges, or as shrubs, rather than as trees, to facilitate the gathering of the leaves.

AN AGRICULTURAL GLOSSARY—THE CORN CROP.

It is suggested by W. P. Vail, of Stroudsburgh, Pa. that we give a glossary of those terms in the art and science of agriculture, which are not generally understood. We gave a glossary of chemical terms in No. 1, of vol. iv. and we propose to carry out further the suggestions of Mr. Vail, as soon as opportunity will permit.

Mr. Vail says, that twenty-five bushels of corn per acre is deemed a good average crop, in his neighborhood; and that his neighbors are rather sceptical of their being able to get eighty bushels per acre. If they will plant northern seed, at the distance we plant, feed every acre with twenty-five good loads of long manure, on a dry sandy or loamy soil, and cultivate as we cultivate, our Stroudsburgh patrons may have their doubts removed in this matter. The great bar to heavy crops of corn at the south, is the tall habit of growth, which necessarily requires thinner planting, and, we fear, a scantiness of dung to feed the crop. The Pennsylvania mode of planting, 4 by 3, gives but 3,600 hills to the acre; and if there are but two stalks in a hill, it gives but 7,200 stalks. In our mode, 3 by 2½, and four stalks in a hill, we get 5,808 hills, and 23,232 stalks—and every stalk will yield at least one good ear—*if the crop is well fed and well worked;*—but upon poor ground, or even upon rich ground, without good manuring, all the stalks would not produce ears, nor would all the ears be good ones. The business of corn raising is the manufacture of dung into grain; and without a plenty of the raw material, we cannot expect a great abundance of the manufactured article. There is scarcely any farm crop that makes a more liberal return for manure than Indian corn.

THE MULTICAULIS.

"Some complaints are made here by your subscribers," says our Georgetown, (D. C.) correspondent, "because you do not *encourage* the cultivation of the morus multicaulis. Many of my neighbors have been inocculated for the disease, and some have taken it in the natural way. I hope they may not be much *pitted* by it." We hope so too; and doubt the propriety, therefore, of administering *stimulants* during the paroxysm of the *fever*. But we can say to our patrons on the Potomac, that our remarks in regard to the multicaulis have been meant to apply to the north. We do not doubt the tree may grow well, and *sell* well, and become a profitable and useful article of culture, perhaps in all the country south of New-York—but *here*, while we think it no better than other and hardier varieties, we should feel it a dereliction of duty to encourage its extensive culture, especially if it is to be purchased at the present high prices.

THE DESTRUCTIVE SYSTEM.

Luke Fish writes from Brush Creek, Ohio—"We are three miles east of the *Great* Miami, which, by the way, is not very great here. Our land is very flat in general, with large timber, beech, ash, bur-oak, hickory, lime, poplar, elm, buckeye and some walnut. Land rates from ten to twenty dollars an acre. Farming with us is in a most wretched condition—to take *all off*, and put *nothing on*, is all the go here." This system has been *all the go*, in the old east, till the meal-chest has become empty—the field wretchedly poor. We beg our patrons in the west to pause, and to consider the inevitable tendency of this *destructive* system of farming.

NEW DISCOVERIES.

A worthy friend in Lancaster co. Pa. B. Clendenon, writes us, what seems to be new to him, and what we fear many have not yet found out—1. That our doctrine in regard to manure constituting the proper food of plants is orthodox; for, says he, "some corn that I manured lightly, was fifty per cent better than that alongside without manure;"—and 2. That the government expends millions of dollars annually, "for the benefit of the commercial interest, while the agricultural interest is left to take care of itself, though I admit it is incidentally aided by commercial facilities."

EXPERIMENT IN HARVESTING CORN.

S. Hitchcock, of Sharon, Ct. has sent us the result of an experiment which he made last season, in harvesting Indian corn; and we are pleased to find that the result corresponds with the results of our experiments, made in 1837 and 1838—and shows a manifest advantage in *cutting up* over *topping* the stalks. "I counted off 48 hills," says Mr. Hitchcock, "and cut them up at the roots. I counted off other 48 hills, and topped them according to the old mode. On harvesting, I found by weight, that there was at the rate of eight bushels per acre more corn on the cut up, than on topped corn. There was no manure on the spot experimented upon, and the crop was not large, otherwise the difference might have been greater."

Mr. Hitchcock asks what grasses will grow in a maple grove. It will be difficult to make any flourish, unless the ground is first ploughed. The orchard grass and white clover will, we think, do best under the shade of trees.

REARING CALVES WITHOUT MILK.

We have several inquiries as to the most economical mode of rearing calves. The practice of many, and we are included in the number, is to take the calf from the cow at three days old, and to give it sweet milk ten or fifteen days, and afterwards skimmed milk, with a gill of flour or Indian meal, till it is fit to wean, at twelve weeks old. This is the common mode. The following, from the Bath Society papers, is perhaps a better, if not a cheaper mode.

"The following is as near a calculation of the expense of rearing my calves, without milk, as I can at present assert. In the year 1787, I weaned seventeen calves—in 1788, twenty-three, and in 1789, fifteen. I bought, in 1787, three sacks—[three bushels each]—of linseed; I put one quart of the seed to six quarts of water, which by boiling ten minutes, became a good jelly; this jelly is mixed with a small quantity of tea of the best hay, steeped in boiling water.

"Having my calves to drop at different times, I did not make an exact calculation of the expense of this hay-tea; but out of my three sacks of seed, I had better than two bushels left at last. I gave them the jelly and hay-tea three times a day. To the boy who looked after them, 6d. (11 cents) per day: the price of the linseed was 4s. 6d. (say $1) a bushel: the whole three years' feed £2.5s. ($10.) My calves are kept in a good growing state, and are much better at this time than my neighbors, that are reared by milk; they do not fall off so much when they come to grass."

We beg of our dairy folks, who are in the habit of murdering their calves at their birth, to save milk, to try the above mode. Here were fifty-five calves raised at an expense, in linseed jelly, of about 18½ cents each, with hay-tea and attendance, as cheap here as in England, without a particle of milk. If interest does not prevail, humanity should.

As a cure for *scouring* in calves, mix a ball of wheaten flour and chalk with gin, and give them—or lay before them a lump of chalk, which they can lick.

To young calves, the food, be it sweet or skimmed milk, hay-tea or linseed-milk, as it is called, should be given of a temperature similar to cow's milk when first drawn; as they advance in age, the heating may be gradually dispensed with; and wisps of hay should then be placed before them, in order to induce them to eat. Barley, Indian corn and oat-meal may be given in small quantities in their drink, and increased as they advance in growth. Beets, shredded fine, are said to be excellent for calves, when they get four or five weeks old.

MR. OSBORN'S PREMIUM CORN.

Mr. Osborn has felt called upon, by the remarks of Mr. Dodd, to send us a corrected statement of the profits of his corn crop. He has made his crop debtor for board, threshing, keeping team, &c. a little more than $17, in addition to his former charges, making the expense of an acre $37.85. The manure he still makes no account of, as he says it will sell for nothing, and he can get it from others for carting away. But he also adds to the credit side $6 more for stalks, upon which he says he has kept almost entirely sixteen head of cattle during the winter; and he also raises his corn to $1 per bushel, the market price. So that in striking the new balance, he makes the nett profit of the acre $96.65, instead of $87.71.

TRANSPLANTING EVERGREENS, &c.

Mrs. Sarah Battell, of Norfolk, asks directions for transplanting the white pine and rhododendrons. In addition to the directions in our last, we advise, that a circle be made round the pine or rhododendron to be taken up, with a spade, of such diameter as to embrace the principal roots; that the spade be inserted six or eight inches, or below the roots, and that the plants be lifted carefully, with as much earth as will attach to them, and that they be planted two inches deeper than they stood in the forest, and the roots covered with litter, well wet, and then with earth. In this way we transplanted six large white pines on the 8th July, at midday, thermometer at 82°, and the sun shining bright—all of which lived and are doing well.

We recognize in our correspondent, an amateur florist and pomologist; and we would be glad to instruct her in the means of preserving her fruit trees and her flowers. The diseased branches of the plum should be cut off and burnt *as soon as the disease appears*, and not *periodically*, as has been the practice of our correspondent. We have improved the health and growth of our pears, we think, by throwing round the collars of the tree some shovels full of tan. We have considered a clay soil so essential to the plum and pear, that we have deposited a barrow full of this earth in the hole intended for a plum or pear tree, and about its roots.

The *Brake—(Fern)*—of which our fair correspondent's neighbors complain, and which one says, "will ruin me—will run out my pasture and my meadow," can only be overcome by labor and perseverance—by subjecting the land to thorough tillage, and by collecting and burning, when necessary, the *root* of the evil.—*Ferns*, of which there are many species, are cultivated in Europe, as rare and scarce plants, but in no case, we believe, as useful ones. And yet they cannot be said to be without their use: they admonish the slothful, that if he would enjoy the treasures of the soil, he must win them by the "sweat of the brow." Mrs. Battell's "Cardinal," or "Eye-Bright," is noticed in our floral department, under the name of "*Lobelia*," which is the Cardinal flower.

QUERIES.

"1. What kind of manure is best for a sandy soil, with clay three feet below the surface?

"2. Is deep or shallow ploughing the best mode to protect such a soil, in order to make it produce clover, or small grain?"

ANSWERS.

1. The answer to the first question depends upon the inclination of the surface; but any vegetable or animal manure is good. If the surface is flat, the soil will be inclined to be cold, and will be benefitted by warm unfermented manures; if sloping, fermented or colder manures may be preferable. Unfermented manures should be applied to hoed crops; fermented manures may be applied to small grain crops.

2. The deeper the better, to the extent of twelve inches, provided that the soil to this depth can be made sufficiently rich. Deep ploughing, with the above contingency, should be resorted to once in a course of crops, be it a course of four or six years. But if the soil is poor, it should be deepened gradually, as the means of fertility can be imparted to it.

TEA TREE.

Geo. N. Burwell, of Buffalo, wishes to know the address of the gentleman who cultivates the tea tree, so called, in Ohio. Who will inform him?

The greatest clogs to improvements in agriculture, are indolence, ignorance, and self-conceit; wherever their influence extend, they paralyze the very earth, and produce sterility.

CORRESPONDENCE.

Leached Ashes and Brine—Steaming Ruta Baga.

New-York, April 12, 1839.

Judge Buel—I noticed in your April Cultivator, a communication on the subject of the use of leached ashes, and suggesting advantages to be derived from a mixture of salt or brine, in its application, of which I am disposed to think favorably, and shall try its utility in the western part of this state, where the soil is of a sandy and gravelly loam, and where we have abundance of leached ashes, & where we have used them without much apparent advantage. I, however, must differ entirely with Mr. Easton, as to its utility upon clay soil, having used it in connection with a few loads of manure, at the rate of seventy-five bushels to the acre, some twenty-five years since, on a clay soil, some two miles west of Hartford city, where nothing but five fingers grew; a very stout crop of herds grass and clover was brought forward the first season, and continued a first rate piece of meadow for some years, until I removed from there. And had I clay soil now, I should apply ashes, with perfect confidence of its great advantage.

The distribution of saline qualities over land, must, I think, be attended with beneficial effects. We may at any dry time observe the dampness of the soil where there has been brine turned out, continuing for a length of time; and from this fact, we have a right to anticipate advantages. Its connection with leached ashes may be advantageous, or it may not, farther than in the mode of distributing it. This we must learn from future published experiments.

One of your correspondents complains of the quality of his beef, as made from ruta baga, which I suppose must arise from his having fed it raw. I had a steamer put in operation last fall, made sufficient to contain twenty-five or thirty bushels, which were well steamed in less than three hours; and several hogs and one ox, were fed and fatted on steamed rutas. The ox, with about six weeks feeding, made very fair beef, and my folks say they never ate better. There can be no question but steaming is a great improvement in feeding all kinds of roots, and I am inclined to the belief that all unpleasant flavors may thereby be avoided.

My box for steaming, was made with a door on top, to put in the roots, with a door at the end to haul them out when done, into a cooler, secured by scantling, let in to each other, in the manner ship-carpenters steam plank.
AGRICOLA.

Inducements for Cultivating Fruit.

J. Buel, Esq.—Feeling desirous in common with you as conductor, and the numerous readers and correspondents of the Cultivator, of "improving the soil and the mind," I have taken the liberty of extracting from a periodical I took some years ago, from a subject the title of which is "Fruit a substitute for ardent spirits"—The writer says, "I am fully of the opinion that the habits of temperance and intemperance in different nations, are to be ascribed to some extent at least, to their possession or want of an abundance and variety of fruit, particularly of the finer and more delicious kinds.

The temperance which prevails in the south of Europe has been ascribed to the general use of wine.—That this is a cause of very considerable influence cannot be doubted. For the tendency of wine to produce an intemperate appetite is far less than that of distilled spirits or malt liquors. But when it is considered that in the northern countries of Europe, those wines only are held in estimation which are fitted to produce excitement, and that to a considerable extent they are subservient to intemperance; while in Italy, for instance, where intoxication is of exceeding rare occurrence, those wines are preferred which are sweet and pleasant to the taste, and that they are used solely for the purpose of refreshment; it becomes necessary to look out for some other cause for the singularly temperate use which is made of wine itself in the southern countries of Europe. This cause, it is believed, will be found in the use of fruits, which are very abundant in those countries where the vine flourishes. But the tendency of wine to create an intemperate appetite is comparatively so small, the quantity of weak and therefore harmless wine made and consumed in countries producing the vine is so great, and so excellent is the fruit itself, that the vine may doubtless with propriety be cultivated for the purpose of checking intemperance.

In the United States of America, though well fitted for the production of fruit throughout nearly their whole extent, drunkenness or intemperance is every where common. This may perhaps be considered an anomaly. But it admits, I think, of a satisfactory explanation. The original settlers of this country were principally from the British Isles, and brought with them a taste for fermented liquors, which they had contracted in their native land. For a long period they were of necessity wholly destitute of fruit, with the exception of a few inferior kinds which grew wild. And even to this day the more delicious fruits, such I mean as are suited to the climate, are by no means extensively raised. On probably nine-tenths of the farms in what may be termed the old states, there is little fruit of any value, with the exception of apples, and these often not grafted. Peaches were formerly common, but now they are very rare, though with a little pains easily raised in any quantity. English cherries, with the exception of a few places, are by no means abundant. Good pears in any considerable variety are seldom seen. And strawberries, raspberries and gooseberries, are cultivated in only a small number of gardens. Here and there an individual is attentive to the raising of fruit. Though but few families, probably not more than one in five hundred, are well supplied the year round with the various fruits suited to the season. Hitherto, therefore, in this country the use of fruit can have had but a partial influence in promoting temperance.

The manner in which fruit is made to supply the place of fermented liquors is easily explained, and the statement, it is believed, will correspond with what most persons have experienced or observed. In the intervals of our regularly established meals, we all occasionally, and very many of us constantly, either feel, or fancy that we feel, the need of some slight refreshment. At such times, if fruit is not to be had, many persons resort to fermented liquors, and thus insensibly lay a foundation for intemperance. But if they are in possession of delicious fruits, these are almost always chosen by temperate people in preference to the choisest wines. This need of refreshment is more especially felt in summer, consequent upon the exhaustion occasioned by heat and fatigue. Fruit is then found to answer the double purpose of quenching thirst, and recruiting exhausted animal nature, and in the most perfect manner. It is a consideration also worthy of remark, that when our friends visit us, the feelings of hospitality very justly prompt us to set before them some refreshment, a refreshment not only generally acceptable, but often needed. Those who have no fruit very commonly offer their friends some kind of fermented liquors, the very thing, perhaps, which is neither needed nor desired. But those who have fruit, almost invariably bring it forward, and to the evident satisfaction of their guests. And when fruit and liquors are both presented, the first is seized with avidity, and the wine, the strong beer, and the spirits are generally left untouched. The man, indeed, whose appetite is not satisfied with the delicious fruits alone, already possesses a dangerous fondness for spirituous liquors. It may be thought by some, that the laboring classes of the community would set but little value upon the substitute here proposed for ardent spirits. Whether they would or not, it is certain that the use which they make of ardent spirits is detrimental.—But what reason can be assigned why they should value fruit less than other men. They have the same appetite, and fruit is equally refreshing to them. The reformation of drunken laborers, by the substitution of fruit for ardent spirits, is certainly not expected; nor indeed the reformation of any class of drunkards. But in those cases where the natural taste has not been vitiated by the use of ardent spirits, it is believed that fruit would be chosen by laborers invariably, in preference to ardent spirits—allowing at the same time, that they were properly aware of the danger of intemperance. Nothing certainly can be conceived of, more suited to the wants of a laborer, toiling in the dust or sun, athirst and weary, than a plate of strawberries, a melon, or basket of cherries, or peaches, or apples.—With these and other fruits, which might easily be raised in sufficient abundance, together with some simple drinks, as common beer, milk and molasses and water, and cider when desired, the laboring classes of the community would undoubtedly be able to perform the greatest quantity of work, with the highest health, and in the best spirits.

The expense of cultivating fruit is much less than is generally supposed. In the court-yards and gardens connected with most houses, there is ground sufficient—and ground usually unoccupied—for raising in abundance, every variety of fruit suited to the climate, with the single exception of apples. The original expense of procuring the trees is trifling; and even this may soon be wholly saved, by a little pains in raising them. That which is indispensably necessary, and which constitutes the principal difficulty in the way of procuring fruit, is the frequent attention requisite for preserving the trees from injury while young, for improving the fruit by introducing good sorts, and keeping up a continued supply. But this requisite attention makes no serious encroachment upon the time; and those who have bestowed it, have found themselves abundantly compensated by the pleasure and healthfulness of the occupation, aside from the direct enjoyment of their labors.

Very great exertions are now making, to banish all improper use of ardent spirits from our land. In these exertions, every Christian and every philanthropist must rejoice. Since the commencement of these exertions, the importance of providing substitutes for ardent spirits has frequently occurred to the benevolent, and various substitutes have been suggested. In recommending fruit for this purpose, it is not designed to have it take the place of other suitable substitutes; but to have it introduced into their number, with that rank and importance in the scale to which its just claims may entitle it."

If in your judgment, there is any thing in the foregoing extract, worthy a place in the columns of the Cultivator, you can insert it. It is submitted entirely to your consideration. Yours, SIMEON McCOY.

Deckertown, March 1st, 1839.

Query.

Westmoreland county, Va. 1839.

The machine for taking off the heads of clover seed, having performed its office, how is the seed to be cleaned, or prepared for market? An answer to this would greatly oblige A SUBSCRIBER.

ANSWER.

The seed is to be taken off in a machine constructed for this especial purpose, called a clover machine, which costs $60 to $70, one of which will serve for a neighborhood. See article Clover, in the editorial department of our March No.

Inquiries in regard to Hedges.

Saline county, Mo. February, 1839.

Mr. Buel—Sir—Permit me to say, that I feel highly gratified to find developed in the columns of the Cultivator, so much useful information to all classes of society, and that I feel a particular interest in common with many of my fellow-citizens, in its circulation and the adoption of its principles in the far west.

Agricultural improvement is certainly one of the most laudable of all pursuits, for thereby the interest and happiness of all classes of society are greatly advanced; and as this seems to be the primary object of your highly useful periodical, permit me, sir, to draw your attention, and, (through your columns,) also your intelligent correspondents, to a circumstance relative to some of the most fertile districts of country west of the Wabash and Mississippi rivers, which greatly retards the progress of agriculture and population: It is the very great scarcity of timber for fencing. This circumstance is at present a barrier to a large portion of our country, best adapted to agricultural purposes. Your attention therefore, to the following inquiries, sir, will be very gratifying, and may be extensively useful in the great valley of the Mississippi.

Can we not enclose land by hedging? If we can, what is the best mode or material to be used for that purpose? How should the hedge be treated, and where can we get the seed or quicks? Will not the pyracantha, or evergreen thorn, answer for that purpose? Can any kind of shrubbery be made to grow, to hinder animals from the size of a pig to the sturdy ox, from passing through or over it? Please to give us such information on this subject as may come within your knowledge, or that may be communicated. In doing so, you will, no doubt, save us from many fruitless attempts in the way of fencing, and confer a favor not to be forgotten.

We feel, sir, that we have a right to view the situation which you now occupy, (compared with our opportunity of information,) as a focus of intelligence, on the subject above stated. Any observations, therefore, which you make, (apart from our particular inquiries,) will be gratefully accepted. A. F. BRUCE.

REMARK.

The subject of hedges has been fully canvassed in our fourth volume, to which our correspondent is referred. We doubt if the evergreen thorn would be stout enough to stop cattle. The seeds of hedge plants, and of forest trees, might be obtained from the Atlantic border. See our numbers on planting, volume iii.—*Cond.*

New Disease in Sheep.

Moray Farm, Fairfax co. Va. Feb. 22, 1839.

J. Buel, Esq.—Dear Sir—Will you allow me to solicit your aid in eliciting information through the columns of the Cultivator, which may enable myself and others to understand the cause and treatment of a disease which has recently attacked my sheep. The subjects affected are ewes with lamb. The symptoms, in most cases, are total blindness—a twitching of the limbs, similar to a nervous affection—apprehension of fear, and a state of indolent lassitude, much inclined to lie down, from apparent stupidity. The symptoms in all are very similar, with the exception of the loss of sight.

While writing, will you allow me to request Mr. Whalen, who speaks of his drill-barrow, at page 59, volume 5, of the Cultivator, to favor the public with a description of it. By so doing, I presume he will much oblige many patrons of the Cultivator. Yours respectfully, LEWIS BAILEY.

Culture of the Mulberry.

Judge Buel—Sir—In the spring 1838, I made a plantation of ten thousand white mulberry trees; and the success and trifling expense with which it was effected, have induced me to offer to you for publication a detailed account of my operations, with an estimate of the expense.

In the spring of 1836, I made a small experiment in raising the trees, which was so successful that I determined to attempt the making of a plantation; and purchased from Mr. Thorburn, of Albany, about six shillings worth of seed, which I sowed on the 24th of May, 1837. The land was a light sand, sufficiently rich to afford corn at the rate of thirty-five or forty bushels to the acre. It was prepared for the seed by once ploughing, harrowing and raking. The line was laid down, and drills about half an inch deep, were made with a pointed stick. The seeds were sown by hand, care being taken to drop them in the bottom of the drills: and not to have them so thick as to rise in bunches. To expedite the vegetation of the seed, which, in the mulberry is slow, I poured upon the seeds about a quart of water, as hot as the hand could bear, and left it to cool; then pouring it off and covering the seeds, they were put in a warm place and permitted to stand over night, and just before sowing, they were spread to dry, so much as to prevent their sticking together. The drills were three feet apart. The mulberry plant is small and delicate on its first appearance: and the first weeding is not only somewhat tedious, but the young mulberries are often pulled out, along with the weeds To obviate these inconveniences, I carefully marked the exact course of drills by setting up small sticks at convenient distances along the drills, and pulled out the weeds as fast as they appeared, and before the mulberries came up. After the plants were up, they were kept free from weeds, by frequent hoeing and hand weeding. The bark of the young mulberry, at the surface of the ground, is so delicate that it is often destroyed by the frosts of winter. It is expedient, therefore, to protect them by a covering of litter from the stable, before the hard frosts of the fall. By this means, my mulberries to the number of nine thousand, were carried safely through the winter of 1837–8. In order to have them ready for transplanting, I raised them out of the ground early in May; tied them in parcels of fifty each; cut off the tops within an inch or two of the ground; cut off the tap-root, and such roots as were wounded in the taking up, and buried the plants in the earth to protect the roots from injury by drying. Thus far, I kept no exact account of the labor bestowed, and must rely principally upon estimation. But as the details are given, every one will be enabled to correct my estimate, to suit his own judgment and circumstances. The same remark may be made as to the expense of preparing the ground for the plantation; the soil of which was very similar to that in which the plants were raised. It had been under the hoe in 1837, and was ploughed in May, and harrowed. It was then laid out in broad furrows, six feet apart. To make the furrows straight, I set up a line of stakes about four feet high, quite across the field. By this line of stakes, the ploughman struck his furrow, passing directly over, and ploughing down the stakes; then turning and passing the plough in the same furrow to the side of the field where he began. While he was doing this, another hand set up the line of stakes again, at two paces, or six feet from the first furrow. The ploughman struck his second furrow by this new line of stakes, and proceeding in this manner, the whole field was laid out in broad straight furrows at six feet apart, sufficiently deep and wide to receive the roots of the plants, without the necessity of digging holes for them.

On the 16th of May, 1838, I commenced the setting out of the plants, with four ordinary field hands, wholly unacquainted with such work. Each man took his furrow and his plants. If the bottom of the furrow was smooth, and sufficiently broad and deep to receive the roots, no further fitting of the ground was necessary; otherwise, the ground was fitted by the hand; deepening, filling up, widening, levelling or smoothing it, as occasion required. The plant was placed on the bottom of the furrow; the roots spread out and covered by pulling down with the hand a sufficiency of earth to hold the plant in place, and pressing it down with the hand. In this manner, the furrow was filled with plants, at about two feet apart. The planter then took his hoe, and drew down the earth about the plant, filled up the furrow, and levelled the earth around the plant; leaving at present, that part of the furrow between the plants, to be filled up at the first hoeing, or sooner if dry weather should follow, and threaten injury to the plants.

On this day, the four hands set out four thousand plants. On the 17th, one of the two best hands was taken off, leaving only three hands in the field; but these three set out four thousand seedlings, and about fifty plants of two years growth. The setting of the residue of the ten thousand was done at intervals, but with equal despatch. Thus the setting out of ten thousand trees was accomplished with eight and a half days' work of ordinary and inexperienced field hands, and the whole expense of the plantation, as it then stood, did not exceed fifteen dollars. That the work was well done, appeared from the subsequent growth of the trees; some of which rose to five feet, the whole averaging about two and a half feet. A very inconsiderable number of the plants perished; but I do not believe that a single good one failed by the operation of transplanting. They now appear to have gone well through the winter. The ground occupied by the plantation is three acres, by estimation. The items and estimate of expense stands thus:—

ESTIMATED EXPENSE OF REARING 10,000 PLANTS.

Ploughing and harrowing 1-5th of an acre, by estimation,	$0 40
Raking the ground and making the drills,	0 25
Sowing the seed and covering it,	0 25
Seed,	0 75
Weeding and after culture,	1 25
Covering with litter in the fall, one day,	0 75
Taking up and tying in parcels of 50 each, 2½ days	1 87½
	$5 52½

Expense of preparing three acres of ground for the plantation.

Ploughing, harrowing and furrowing, estimated to be equal to the work of a man and pair of horses three days; but as corn was planted between the rows of trees, only half the expense of ploughing, &c. should be charged,	3 00

Actual and known expense of setting out 10,000 *trees.*

First day, 4 hands, at 75 cents for wages and board, set out 4,000,	3 00
Second day. three hands, 4,050,	2 25
Setting out the remaining 1,950, at the same rate,	1 12½
	$14 90

Our farmers, fearing the expense, and unacquainted with the culture and habits of the mulberry, are reluctant to enter into the silk-growing businss. No farming operation, however, is more easy. It resembles, in every particular, and almost exactly, the field culture of the carrot, and I do not know that it costs more to raise a seedling mulberry, than it does to raise a carrot. The work may be performed by the farmer himself, and a small plantation of 3,333 trees, occupying one acre, made with a very few days' labor, and without the expenditure of a shilling in cash, except for the purchase of a paper of seed. The price of labor or board may be thought by some, perhaps, to be too low; or that the estimate of the quantity of labor bestowed on some of the operations are not sufficiently high. Let such add any amount, to either labor or compensation, which good judgment may deem sufficient; still the expense of a plantation will be trifling, and within the means of any one who is desirous to embark in the business. The tree is very tenacious of life; it will bear stripping of its leaves to a moderate extent, the next year after transplanting, and then begin to yield a return for its cost; the silk worm is healthy, and the attendance it requires can be performed by children, aged people and females; its profits are greater, its risk less, and the labor it requires lighter, than any other farming operation; its production is easily and cheaply transported to market, and meets a ready sale, at a high price.

Why, then, should our farmers longer delay to enter upon the raising of silk, by which they will enrich themselves, render our country independent of foreign nations for our supply, and save at home those millions which are every year sent abroad for its purchase.

R. WESTON.

Sandy-Hill, Washington county, State of New-York.

Light Crops, &c. in Illinois.

Naperville, Ill. March 19, 1839.

Last year, in this section, it was rather discouraging to farmers; on account of the drought, not one-half a crop was realized. Spring wheat very poor—oats very light—last fall very dry; what winter wheat was sown, not one-half came up; I sowed fifty acres, and I do not think that over one-third of that came up. This spring some of it has shown itself, that did not make its appearance last fall; what it will amount to, I cannot tell. The farmers here, generally, are afraid to put in fall wheat, from the fact that much of it kills out during winter and spring. I should judge that the system of farming in this country was bad. Before ploughing, they burn off the stubble, and all other matter which will burn; their straw, instead of converting it into manure, they pile up and burn to get it out of the way. Thus the land is left without support, except from the ashes made from the burning stubble and grass, which does not amount to much in my opinion.

There is a kind of wheat in this country, which by some is called Italian, and by others Siberian; it is a hard flint wheat, large heavy kernels, weighs from 62 to 65 lbs. per measured bushel. Our millers complain about grinding it, on account of its being so very hard. We have another kind here, that is also by some called Siberian, and by others Italian; this latter kind is large kernels, not so heavy or hard as the first mentioned kind. Can you, from my description, say which is Italian and which Siberian, or is it not either? I intend to sow thirty bushels of each kind this spring, so that I shall be able to determine which is the best yield, and most profitable. Respectfully yours,

LEWIS ELLSWORTH.

Artificial Crossing of Vegetables.

Mr. Buel—Dear Sir—By frequently observing seedlings of different species, and of the same family maturing side by side in the garden of the heedless farmer, I am influenced by a disinterested endeavor to mention the subject of *improvement* and *degeneration* of vegetables, by crossing.

It is a very common saying with us, "my seed has run out," when in fact, instead of "running out," the plant, if rightly cultivated, may retain its first purity, and in most cases advance its fecundation, and be beneficially improved.

With many, the common practice is, to select a place in the garden to propagate the beet, turnip, cabbage, onions, &c. of the same and different species, all mingling side by side, seemingly not aware that although the parents may be of a different species, the progeny in the vegetable kingdom, as well as the animal, are inclined to take a new form. It being the natural tendency to mixture in corn, potatoes, cabbage, artichoke, turnip, beet and radish families. Therefore, to retain the present qualities of each variety, the different kinds should seed by themselves, remote from any other species of the family.

Several species among the common productions of our country may be *improved* as well as *degenerated.* Among these are wheat, rye, oats, Indian corn, pease, beans, potatoes and the squash.

The specific change in vegetables, as well as in animals, can be produced only by a slow and gradual process, a valuable property which at first is merely accidental, may, from one generation to another, by a repetition of impressions, become at last confirmed and hereditary.

When new properties are impressed on one generation, they are in some degree inherited by the next, which, after receiving additional and stronger impressions of the same kind, at last the effect is carried to its ultimate point, by selecting the best for propagation from year to year.

The new and choice varieties may be retained, if not carelessly allowed to grow among, or alongside of other inferior species, being exposed to impregnation by the male parent of its inferior, while in blossom.

I have seen this strikingly illustrated, by an experiment on the *pie plant* or *American rhubarb.* The common yellow dock grew near this vegetable, and by a few crossings, a new variety was produced, which partook of the nature of both. Your patron,

SOLOMON W. JEWETT.

Weybridge, 10th April, 1839.

Millers' Tolls.

Burlington Co. N. J. 3d mo. 11th, 1839.

Friend Buel—I had presumed that any thing more on the "vexed question" of "millers' tolls" was inadmissible in your columns; but inasmuch as you have seen proper to open them again, not only in regard to an experiment which it was obligatory upon you to notice, but also some erroneous remarks of a personal character, on which account I think I am entitled to be heard again, after which I bid adieu to the subject and to your correspondent William A. Stone, whose optics, whether natural or artificial, are possessed of too great magnifying powers, presenting that to his vision which never existed; for he cannot show in either of my communications where I have said that all the loss alluded to is to be attributed to fixed air, or that all solid bodies contain it; and I consider his declaration of it but a forced construction of my words, or the effusions of a volatile imagination that can dress off an idea in a garb of gossamer to please its own fancy or to suit its purposes.

I consider it of no consequence what the natural causes of the loss may be, or whether one or many. It is not them, but the effect of them that I wished to make known and am much obliged to our friend of Rahway for his assistance in establishing the fact. I also have made an experiment, confirming a part of my premises, viz: on the 21st of 1st mo. last, I accurately weighed a quantity of wheat brought to my mill belonging to a regular reader of the Cultivator, full as clean as is usual to take to mill. I then cleaned it and weighed again, and found it had lost 1¼ lbs per bushel, which add to W. A. Stone's 10 ounces and it will make nearly 2 lbs. per bushel loss. But since your correspondent contends for causes, I am very willing to admit his first to be a prominent one, but his other lighter than air in every sense. But why does he account for only a part of the loss? Is he afraid of the explosion of fixed air? For can he suppose that air does not constitute a part of wheat, and that too in a fixed or condensed state, although it does not grow as large or as hollow as a pumpkin; for the milky substance he speaks of must either harden and condense, or clarify, as in berries. And what does his favorite Blair say? Why that water, air, and all other fluids are in a certain space equally solid with the hardest body. I am happy to congratulate him in converting *ten*-tenths of the agricultural community to the belief that more than one in a hundred parts of their wheat is water, and is absorbed by heat in the process of grinding. Seeing his proof is so positive, for he says, he has lost 10 ounces per bushel; and as 960 ounces make one bushel or 60 lbs; and the 100th part of that is but 9.6 ounces, therefore it must be composed of more than 100 parts of water, and that it is much more philosophical to attribute the loss to it than to suppose it all to be fixed air as Mr. David Walton has. Now I have no objections to his philosophy being received. It will answer my purpose full as well; for it matters nothing to the farmer whether his grain loses by the form of air or water. The object I contend for is granted, and I am now perfectly satisfied. Respectfully,

DAVID WALTON.

Millers' Tolls.

Medford, N. J. 3d mo. 9th, 1839.

Friend Buel—From a previous editorial remark, it would appear you would not readily give insertion to further comments under this head; but seeing in a late number of your paper, not only the experiment called for by the editor, but an appendage of argumentative strictures on previously advanced propositions, I consider (if I meet with a corresponding liberality of feelling and sentiment from the proprietor) I can with the same propriety, take up a small portion of your paper as your correspondent, William A. Stone, who in his last, contends my former assertions are erroneous, by arguments, the principal facts on which they are founded it will be seen are incorrect. He considers it absurd to say wheat contains fixed or condensed air, "which he says, he will not admit without plain proof; because if it contains air while in its milky state, it has more room as the grain grows." This is an error of no small magnitude. The grain with us contracts from its milky state as it ripens. I presume he was rather hasty in making this reply, or at least not prepared to, from actual observation. Though to do him justice, it is believed the cause he assigned for the loss sustained during the progress of the manufacture of his wheat into flour, is obvious, the effect variable, and the result as justly attributable, (from the profound data of O. Evans, whose experiments no doubt were rigidly exact as his own,) to the escape of fixed air or the loss occasioned thereby. But in opposition to the demonstrations of O. E. and to prove the impossibility of my assertions with regard to fixed air, he exultingly declares this wise man has discovered what no philosopher has done before him; referring to his favorite author, and says, Blair's definition of solidity, "is that property which every body possesses of not permitting any other body to occupy the same place with it at the same time." Here he has inappropriately used the quotation of Blair, and for his further information, I will annex, verbatim, the illustration and experiment of this author belonging to his definition.

Illustration.—"If a piece of wood or metal occupy a certain space, before any thing else can take possession of that space, the wood or metal must be removed."

Experiment.—"If some water be put in a tube closed at one end, and a piece of wood be inserted that fits the inside of the tube very accurately, it will be impossible to get the wooden piston to the bottom of the tube unless the water is taken away."

2d. "The experiment may be made with air instead of water."

Corollary.—"Therefore, water, air and all other fluids are in a certain space equally solid with the hardest body."

I cannot conceive how your correspondent, from these quotations, can invalidate my previous assertion; for a few considerations will show, that two bodies of external figure or form, (for these are essential properties of all bodies,) without regard to their size, composition or inherent properties, cannot exist in the same place at the same time. The author, in this experiment, has no allusion to the substances which, by union or chemical combination, form these masses. Analysis has shown, that during the decomposition of wood are obtained a quantity of water, an acid, several kinds of air, and there remains carbon, a black porous substance called charcoal. These quotations from this author only prove solidity to be essential to all bodies, and before one can occupy the space of another in identity, the latter must be removed or annihilated, which is not acquired by human aid. Since the power of Omnipotence was required to create something out of nothing, that same Omnipotence will be required to reduce any thing again to nothing. His inference from that quotation cannot be admitted; thus his anticipations on this score are completely frustrated, while my proposition remains good and authentic. It would be more wise, at least more exemplary, if this man before making public harangues on the wisdom of others, would be more lavish in giving his own publicity. The critic catches at the word fixed or condensed air, (which I connected as synonymous terms, and are equally appropriate as his own "loose" air,) for there is as much reason to believe it exists in a fixed as a "loose" free state. In his last communication I find no proof against the point I contend for; and from the determination Oliver Evans made to write on this subject, I believe justice was his motive, and his knowledge deduced from experiment and observation; who for many years pursued the business of a miller, and understood the mechanism of mills for grinding wheat and other grains, and at that time was the most skilful millwright and experienced miller in this or perhaps any part of the United States.

From renowned authority, I assume my statement to be correct, and do scrupulously adhere to it until the contrary shall be proved. Respectfully, &c.

SILAS WALTON.

Suggestions to Builders of Stone or Brick Houses —Asphaltum Pavement.

New-York, March 18, 1839.

J. Buel, Esq.—Dear Sir—Having been engaged in building some fifteen years, and feeling much indebted to others for the useful information I have received during that period, I will offer a few remarks in answer to the second and third queries of your subscriber at Morristown; and although they may not benefit him much, they may be of service to those who have yet to erect country dwellings. To such I would say, never erect a house of brick or stone, unless overruling circumstances compel you to adopt that course. If so, fur off all your outside walls with joist or strips of plank, and lath and plaster on them, instead of plastering on the walls. By so doing, a part of the evil arising from a stone or brick building, may be obviated. It is a common opinion, that all the objections to stone and brick buildings in exposed situations, arise from the walls receiving moisture at the surface. That injury does arise from this cause, there can be no doubt; but as human ingenuity and skill can overcome it, it sinks into insignificance. The irremediable evil exists in the condensation of vapor, with which, I presume, every one who drinks cold water in summer, is acquainted.—The walls of an isolated stone or brick building, will retain the cold they have imbibed during winter, until May or June; and holding an unequal temperature with the atmosphere, will condense all the vapor which comes in contact with them. We often see the water running down the walls and windows, and find the rooms chilly, damp and uncomfortable, while the air out of doors is bland, warm and delightful. This fact could be established by a thousand witnesses, while the cause remains almost unnoticed. A stone palace and a stone prison are alike in one respect at least, and both are destructive of health and comfort, unless they are kept warm by fire, and well aired, until midsummer. I would not increase the chills of those who suffer the evils of a stone or brick house in the country, or any exposed situation, but if I could, I would prevent an increase of the evil. It may be asked why these effects are not experienced in cities where most of the buildings are composed of brick, I answer, they are more compactly built, and the walls protect each other and seven in ten of the rooms have fire in them continually during winter. To your correspondent at Morristown, (and there are others there suffering with him from the same cause,) I would say, if your walls have not been painted or whitewashed so as to prevent the cohesion of mortar, take two parts, by measure, of clean sand, and one of good fresh burnt lime; slack dry; mix and use while hot or warm; lay the coat on thin and float it; finish up like hard finish or white wall, and trowel it very hard and smooth. The plastering should be done early in the spring, and the wall receive a coat of boiled linseed oil in October following; this if well done will make the surface of the wall impervious to water—the only point to be gained—without it, the mortar will freeze off. I think no Asphaltum has been used in this city for covering walls. I saw the two pieces of pavement done with it in Broadway, in front of Nos. 167 and 241, and think it could not be well laid on perpendicular walls. It is prepared with coarse sand, in an iron vessel, over a furnace, and requires a high heat to enable the workmen to mix and spread it. The ground received no preparation, except hard treading; the coat is laid on about an inch thick; short iron bars were laid down twenty inches from, and parallel with the curb stone, and the space filled level with the bars, which formed the line and thickness of the first course; and this process was repeated until the whole was finished. It is smooth, and to this time stands well. I have no knowledge of the expense.

Your remarks, elicited by a former communication of mine, have given me new light on the value of manure in the west. If Mr. Osborn carted out the manure, for the purpose of breaking his steers, I have done him wrong, and ask his pardon for it. I am working a farm by proxy, and would like to have a few pairs of steers broke upon it in the same way. Yours truly,

JOHN M. DODD.

Great Crop of Potatoes.

Middlefield, Mass. March 13, 1839.

Mr. J Buel—Dear Sir—Having read with interest, the various experiments, as detailed by your correspondents, and published in the Cultivator, I thought I would contribute my mite, by giving you the account of an experiment which I made the last season in raising potatoes. The piece of ground upon which the experiment was made, contained eighty-two rods, planted the previous year to corn, yielding about twenty bushels of unsound corn. Upon this ground I spread nineteen loads of compost manure, and ploughed it in; I then threw it into ridges of three and a half feet width, planting the hills on each side of the ridge, thus * * * * * * * * * * * * * * * * * hills twenty inches apart. The ground is naturally dry, and the severe drought of last season must have contributed to lessen the crop. The account stands as follows:—

Dr.	To carting and spreading manure, ...	$2 00
	ploughing and ridging, ...	2 00
	11 bushels seed, ...	3 75
	planting, ...	2 00
	hoeing, ...	2 00
	5 days' harvesting, ...	5 00
	manure, ...	7 00
	Interest on land, ...	1 25
	Total, ...	$25 00
Cr.	By 340 bushels of potatoes, at 25c.	$85 00
	Deduct	25 00
	Profit, ...	$60 00

I contemplate making other experiments the coming season, with the different root crops, and if successful you may hear from me again Yours respectfully,

EBENEZER SMITH.

Experiments in Preserving Plants from Insects and Worms.

Huntington, L. I. March 20th, 1839.

Mr. J. Buel—Dear Sir—As the time of planting corn again draws nigh, we begin to think about using some means to prevent the destruction of the seed and young plants, by the grub, wire-worm, birds, &c.

The grub was very troublesome in this section of the country, last season, and I believe there was no remedy better than hunting them out and killing them. Some of your correspondents recommended soaking the seed in warm water, strongly impregnated with nitre, from twelve to twenty hours before planting, and you also recommend a trial of this, and to be favored with the result. We tried it faithfully last season, but we only found that they loved the taste of salt as well as other animals. We carted on our corn ground, a load of old wall, strongly impregnated with lime, and ploughed it under. *No worms troubled the corn where this was put on.* Whilst on every side, they destroyed one-third. In the last May number, page 63, under the signature of "*A Subscriber*," from Dutchess county, feeding the worms is recommended, by laying heaps of mullen, dock, &c. about in your corn, about the time of its coming up. This we have also tried, *with success*. But we only caught the cut-worm. They do but little injury to our corn; but beans, pumpkins, cucumbers, melons, &c. they devour greedily; they come to the top of the ground in the night, and travel till they can find something to feed on, when they fill themselves by eating off the plant near the surface of the ground. If you will take a lantern, and go in the field in the night, where they are plenty, you will see them crawling about in search of food. But the grub that has been so troublesome here, is of a light colour, with a red head, and eats the corn off between the surface of the ground and the kernel, destroying it wholly at once.

Buckwheat sown among turnips will not protect them from the fly, as recommended by "*A Lady*," in the last March number. We sowed a patch of turnips in the middle of a piece of buckwheat, to protect them from the grasshopper; the buckwheat came up all over the patch, and the fly was as thick as I ever saw them any where. I saved my turnips, by putting Scotch snuff on them in the morning, when the dew was on.

H. B. ROGERS.

P. S. Does the Rohan potato vines require to be supported up by stakes? [*Answer*—No.]

Farming—Seed Corn—Calves.

Dear Sir—In offering a few remarks for your consideration, I do not wish to be considered as being actuated thereto by a love of notoriety, or the mere vanity of seeing my name in print. The very flattering notice taken of the contributors to the last volume, in the last number of said volume, is the incentive to the present undertaking. Though I feel willing to give myself a very humble place among said contributors, yet I know that there must have been something worthy of observation in what I have written, or *you* would not, to please *one*, have inflicted a penalty upon *thousands*.—Encouraged by these views, I offer again for your acceptance, a few remarks on the all-important subject of husbandry.

That the tillage of the soil ranks the highest in point of usefulness, of the various occupations of men, I trust there are few or none, in the nineteenth century, to deny. The beneficent Creator of the universe, has connected with this employment, the highest enjoyment of which human nature is susceptible, with the least corroding care. Breathing a pure air, and "catching health from the balmy breezes," rising with the lark and retiring betimes, who so enjoys "tired nature's sweet restorer," as the farmer? He alone that tills the soil receives nature's bounties fresh from her hands; and consequently he only enjoys the produce of the soil in its highest perfection. Though husbandry is generally considered as the most simple of all occupations, there is no one employment to whose aid more *science* can be brought; nor which is more highly improved by the light of science. The greatest talent of the age has been enlisted in its behalf, and every day witnesses more and more of the brightest genius enrolling itself as its ardent admirer and most successful follower.

It is really wonderful, that husbandry, forming as it does the *foundation* of all prosperity, should yet have received so little attention from the legislative wisdom of our country. Much has been done and is doing for schools, academies, and colleges, the object of which is to train the young for mechanics, merchants, lawyers, doctors, &c. This is well; the perpetuity of our free institutions depends mainly upon educating the common mind. But it would be better that attention were given to train more of the young for the healthful, delightful and profitable employment of husbandry. I hope, then, that the agricultural periodicals of the day will exert themselves to attain this most desirable object, and I have been truly gratified to find that yours has done much to forward it.

I will close this article with a few practical remarks on the subject of this communication. My neighbors and I have found, without, I believe, a single exception, that corn planted as it comes from the cob, without any artificial preparation, comes up better, and stands better, than when soaked in any liquid. I, one season, planted corn and put next the corn a handful of unleached ashes, not one grain in a thousand came up; I replanted with corn in its natural state, and it grew well. One of my neighbors desires to state that chamber-lye placed where young calves can get to it, will be greedily partaken of by them, and it promotes their health and growth in a surprising degree; I have not tried it.

The system of agriculture is slowly but gradually improving in this vicinity. Manure in its long state, is more used than formerly; the use of the cultivator in dressing fallow crops is extending; and much more use is now made of clover and other grass seeds, than a few years back. Other improvements might be mentioned, but feeling that I have taxed the patience of you and your readers sufficiently, I close.

E. H. VANUXEM.

Insect Enemies.

Last summer, just after my squash and melon plants put out their rough leaves they were completely riddled by the little striped flying bugs, that literally swarmed upon them. A friend who was visiting me at the time proposed that I should try what had proved to him an effectual remedy: accordingly I put some fresh cow droppings into a tub, mixed therewith water, until so thin that the liquid could be sprinkled over the plants with a whitewash brush. I applied it three times each for two days; the bugs all disappeared from them; the plants soon put out a new and vigorous growth of leaves, nor did bugs again attack them.

ROB. WHITE, Jr.

Shrewsbury, N. J. 3d mo. 25th, 1839.

Farming in Virginia.

Greene co. Va. March 10, 1839.

J. Buel, Esq.—Sir—At this enlightened day of agriculture, there are numbers of people in Virginia, who cut down and wear out one acre of land, to buy another to cut down and wear out, and so on. And finally old age creeps on them, and they find themselves only comforted with but a sun of galls and gullies, the fruits of their youthful labor.

> "For his shrunk shanks, and his big manly voice,
> "Turning again towards childish treble, scisses."

They are no longer able to continue this wretched course; they are brought to rest with this bright example and rich inheritance for their children. Can you not, Mr. Editor, stop them in this wretched system? Can they not be brought to reflect, that their money-purse has a hole in both ends, and that their cash runs out as fast as poured in? Cannot you convince them, that land can be kept at its virgin state, yea, and improved far above it, and at greater profit or saving of labor? I know a number of farms that will not, upon an average, produce two barrels, or ten bushels, of corn per acre, and I overshoot the mark at that. This would appear to you hardly credible, but it is too true.—They certainly do not believe that land can be kept to its primitive state—nor can they believe this exhausted soil can be entirely restored. The new husbandry is what they lack—they do not know how to get out of this old way into the new one. You have the means, and the talents, too, to set them right. This, too, it seems would be a work without faith, for some of them have many fine examples of good farming before them—but some lack enterprise, and others too selfish to take the advice or pattern after others, particularly their neighbors.—And perhaps, Mr. Editor, by its perpetually flowing from you, a foreign and an intelligent source, it may eventually have the desired effect; time will remove the prejudice. For instance, I know a very old gentleman in Albemarle county, who, at one time, (when I was a boy I heard it spoken of,) ridiculed the idea of sowing clover seed—though his land was, I think, then rather under medium quality; but about fifteen years ago, he turned the somerset, and I think I hazard nothing in saying, he is now one of the best and most prolific farmers in that county; his last crop of wheat, I have been credibly informed, was the best in that county—and from the quantity he made, I think two-thirds was the result of the restoration and improvement of his farm. These land killers can see this. Can you not induce them to believe, that it is cheaper to work one acre of land than it is three? I say three, because I think the average crops of new land in Virginia, would be about six barrels per acre, and much far above it. This they would answer as a very simple question.—Why, then, do they work three instead of one, for the same number of barrels? Simply because they have so impoverished their land by this wretched old way.—Persevered in, it takes three acres to produce what they formerly cropped-off of one, and in the latter, the expense increased three-fold in every way—labor and money—and but the same result—how large a hole, too, does this make in the profits. The profits are proportioned by the expense. For instance, a few years ago, when I commenced farming, I had a small parcel of flour sold in market at $4 per barrel; here the expense was one-fourth. My last crop of flour was sold at $8, one dollar deducted for carriage; here the expense was one-eighth, which is less than one-half of the expense when sold at four—though apparently the same, but obviously less than half, for when sold at $4, I had but $3 left, and now sold at $8, I have $7 left, which is more than double of $3, for the same expense. Hence it is plain, that as the profits increase, the expense diminishes, and by this rule I work the renovation of the soil. As the land increases in production, in the same ratio the expense diminishes, or even keeping it in statu quo, increase of expense is prevented.

In the above, Mr. Editor, farmer like, I have given you the true practice of many tillers of the soil amongst us; and if you think it might have a stimulating effect in sliding some out of this bad old way into the new one, and preventing others from getting into it, it is at your pleasure or not, to honor it with a place in your journal, which paper I recommend to every brother farmer.

I have now just finished hauling out my manure.—From my horse stables, in February last, I hauled and spread twenty-two four-horse wagon loads of dung upon meadow land. From my barn-yard, one hundred and upwards, of well mixed, unfermented compost, upon the field I intend for corn, which will be spread only as fast as ploughed under. My manure yard is made in the form of a basin, to prevent the liquid from running off. What straw I generally have left, (which will be nearly half this season,) after wintering my stock, &c. I haul out and spread upon my thinnest land one or two years previous to cultivation. This mode of improving land, from experience, is much faster than ploughing the straw under forthwith. Hence I have come to the conclusion, that the additional improvement gained by covering, over that of ploughing under immediately, is caused by the nitre produced by the shade, and hence I have settled down to give my fields two years successively in clover, previous to fallowing for wheat, or ploughing for corn. The above statement of manure is not given to vie with you northern farmers, nor many in Virginia, but to inform your readers what some of us are doing here, and as a criticism upon some of our soil butchers, who only haul out some eight or ten loads of manure, of the old year's making, upon a little piece of land, for tobacco. In former days, in Virginia, he who cut down and wore out his land the fastest, was said to be the greatest man of business—but the dawning change now cocks up his nose at such a one.

T. G. G.

Much that is to be Commended.

Maryland, March 21, 1839

Mr. Buel—I notice with a peculiar concern and interest, the statement of the condition and circumstances of "Agricola's" farm. His is not a solitary case—there are hundreds of such, and a system that will help them will be doing more than all your premium crops on deep limestone soils, or soils made rich to fatness by the facility of obtaining manure from towns. You may playfully throw the "Yankees" at us, and tell us to follow them—but it won't do, sir. We must have legs like them to walk as they do. *You* made a poor farm rich—so say some of your correspondents. But you were in the possession of the *needful*, and your purchase was near Albany, where you could get lime, and ashes, and bone dust, and street scrapings, and stable manure, &c. Any man that would not make his land rich with all these favorable circumstances, deserves to—— have no land.

My experience and observation tell me, that there is a way for a man to improve a large body of land, without forgetting that he has more than fifty acres, when he has nine times that much. Don't make a man feel poorer than he is, and throw him into the pit of despair! There is no necessity for his forgetting any of his land. Come, don't trump up that old tale, that poor land makes a poor man poorer, just in the ratio of the increased quantity of land he owns, and frighten us from five hundred to fifty acres to make us *feel* richer. No, no! Let him look the whole in the face, without fear or despair. But let him have a beginning—a starting point—any thing within the compass of his capabilities to improve—five, ten, fifteen, twenty acres, or more—let the determined quantity be properly tilled, and manured, and cropped so as to pay its way, and then put down in grass.

As to spreading manure on a sod, and ploughing it down immediately, *true* theory and enlightened experience must condemn it; and particularly if the subsoil be porous. If the manure be mere straw, or grass, or other substances, containing little or no soluble matter, it will be better to cover it any way, without being particular whether it be turned down on the subsoil or not; for fermentation must be promoted, and the gases retained. Here all is right. But when the general term *manure* is used, without a particular application, we understand the productions of our stables and barn-yards. Now, in this kind of manure, there will always be more or less matter that will mingle with the rain, and will pass down into the *pan*, leaving the coarser particles to be formed into manure by the process of fermentation. The loss in this case must be equal to the urine and other finer parts of the manure from the yard.

I admit that manure of all kinds ought to ferment *in* the land where it is to be applied; fermentation and drainage in the yard, reduces it both in quantity and quality; and the sooner manure can be got out and properly covered the better. But it must not, if we would get *all* the benefit, be turned down on the subsoil.

But, say you, how is the objection to be obviated, if I intend putting a grass field in corn, on which I would have my manure? No other way than to plough the ground first—harrow well—then spread your manure and *list* it. By forming the *list*, you throw two furrows together, which will nearly if not quite cover all the manure, if not planted too wide; and by the time you harrow your corn, you will find it sufficiently short to mingle with the earth, so as to prevent loss in fermentation. In this way you get the benefit of all the manure, both of the soluble and gaseous particles.

Now, as Agricola is not to forget that he has three hundred and fifty acres of open land, he is to be kept from despair of ever reclaiming the whole. And to do this, he must see how, after having improved one piece, he can apply his resources to another, without suffering that which he has improved to relapse into its former condition. It will be impossible for him to do this, if he entirely depend on clover. Clover is too soon gone. And to have to return to tillage operations, and of necessity, the application of manure, to this partially improved land, will prevent the advancement of improvement very little if any beyond that which he improves the first two years. If he plough, he must apply manure, or there will be a perceptible retrograde. Plough down clover! Let this be done where it can. But there are frequent obstructions, which I need not stop to notice. Now, if in the list of grasses, any one can be found that will be permanent, enduring for years, and tending all the time to the melioration of the soil, that is the grass *mainly* to be depended on by Agricola, in his reclaiming system. Such a grass we have—orchard grass, or what in England is called rough cock's foot—(*Dactylis glomerata.*)

This once lauded—sometimes abused—and now much neglected grass, is the only one with which I am acquainted, that will fully answer this purpose. Its durability is wonderful. From its early vegetation, it gets the ascendancy of all other grasses, and from the quickness of its growth after the scythe, it keeps it. I have always found, that where land was occupied with this grass, it broke up more mellow and friable than any other. After being six and seven years *sett*, it has ploughed like an "ash heap." It does not only *not exhaust*, but positively adds, from year to year to the fertility of the soil. It makes an excellent hay, when cut in blossom, and one of the earliest and latest pastures. You will find in the 9th volume, page 81, of the "American Farmer," some remarks of mine on the utility of this grass as an auxiliary on a grazing farm. What is said there on the comparative merits of clover and this grass, I have for some time past dissented from.

Let Agricola seed down all the land he has properly tilled and manured, with this grass, and let that stand. "So far, so good." Let him take another piece and do likewise, and by this means he will get round his three hundred and fifty acres. His means to support an increase of stock will grow upon him—this will increase the quantity of his manure, and by the time he gets round, he will have the means of doubling his operations. Your advice, to economise and accumulate all the matter that can be turned into manure, must be strictly attended to. Let all the bare parts of the barn-yard be thickly covered with leaves—two feet thick.—Let all the corn fodder be saved, by cutting the corn off at the ground, and let this be cut up in the winter, by one of Eastman's or R. Sinclair, Jr. & Co.'s chaffing machines; so that instead of feeding straw, he may have all his straw for litter and yard purposes. Let him raise mangold wurzel and sugar beet, and *try* a little ruta baga. This last does not often succeed, this side the Delaware river. If his land *require* plaster of Paris, let him use it, and if spared a few years, he may *think of all his acres*, with more satisfaction than despair, any how. Z.

A fact or two on the operation of plaster, as I have yet a scrap of paper unoccupied. I have seen a fine limestone land, after having been reduced by a succession of white crops so that it would not bring ten bushels of wheat the acre, restored in a few years, by the application of plaster. One field of this description I saw the clover hay and seed mowed off three years in succession—then ploughed and bring a heavy crop of wheat. The clover could not have produced this effect as a manure. There are other lands on which plaster makes but little impression. If plaster only acts as food for plants, what can make this difference? May it not bring out the carbonic acid gas, latent and inert, in the subsoil of limestone lands, so it can be reached by the mouths of the plants?

A hit some time or other *may be* on your summer pruning.

A new Correspondent,
But an old Thinker.

The Silk Business.

Shrewsbury, N. J. 3d mo. 25th, 1839.

Jesse Buel—Dear friend—From some notice of the proceedings of the *Convention of Silk Growers*, lately held at Albany, I see that it had decided to form a *State Silk Society*. There has been one organized in New-Jersey, and in Pennsylvania they have a *Sugar Beet Society*. Is it not questionable whether thus dividing the strength of the farming interest into various and distinct associations, will be the best means of establishing permanently any particular branch? If it be not, then those mostly engaged in raising corn, growing wool, breeding cattle, &c. &c. may each get up a society to promote such business exclusively.

I do not see it avowed by those who have associated to further the silk business, that the growing of food for man and beast is to be superseded, or that wool and cotton may not still be used as a part of our clothing; but on the contrary, the producing of silk is urged upon the attention of every farmer, as being an *addition* and an *auxilary* to the ordinary course of husbandry, which if combined therewith, promises to increase the profitable use of land, labor and capital. There is no doubt in my mind, of the correctness of this view, nor yet of the vast benefit already conferred upon the country, by those who have so zealously and praiseworthily labored to enlighten our farmers on this subject. The success of a small experiment made by me last season has encouraged me to increase my investment in the silk business twenty-fold this, and my limited influence has been used to induce others to embark in it

I have been looking for a caution from thy able and ready pen, against the getting up of these separate and unconnected societies, and to encourage the concentration of strength and unity of action amongst us in county and state agricultural societies, as one means of placing agriculture in this country, in proper relative posi tion with manufacturing, mercantile and professional business. If we silk folks would but take our place in agricultural societies, and trust this particular branch to the action of committees, would it not be as effectuly promoted?

Having thus mentioned what I have thought to be a matter of some importance, I leave it with thee, not doubting that if it really is so, it will be duly considered and attended to. Respectfully thy assured friend,

ROB. WHITE, Jr.

Encouragement to Agriculture, &c.

Brooklyn, March 15, 1839.

Judge Buel—Sir—Your zealous and efficient efforts to promote the agriculture of this country, continue to produce results which justify the most sanguine anticipations. Science must be combined with practice, to effect great improvement in any art, especially in agriculture. This desirable end cannot, I conceive, be better attained than by the establishment of agricultural schools, which you so ably advocate. I have been led to this reflection, by noticing the following extract from the late annual report of the Treasurer of the United States:

"It is an interesting fact, that during the last three years, more than $86,000,000 annually, or an average of nearly *nine-tenths* of our whole domestic exports, have been derived from agriculture. More than *seven-tenths* of our whole population, are probably employed in that useful pursuit."

What a commentary upon the neglect of this subject, by our State and National Legislatures. It is a lamentable fact, that political strife has engrossed the attention of our Legislature. Who are responsible for this neglect? I, sir, can assign the responsibility where it mainly belongs, but where it is rarely charged. The *public press*, (exclusive of agricultural journals) are censurable not only for *failing to aid*, but actually for *retarding* improvement in agriculture. The enactments of the Legislature are made in unison with *public sentiment*: which is controlled by the press. Am I not therefore justified in charging the responsibility upon the press? I have facts, however, to support my case: I will cite but one. The New-York Courier & Enquirer of the 24th March, 1838, after stating that $77,000 had been paid by the State of Maine, as a bounty on wheat, thus remarks:

"It would seem that as in other countries, the absurd notion is exploded, of encouraging by legislative grant, the pursuit of any particular branch of industry; in the United States, it is immediately taken up and acted on. What can be more in opposition to every sound principle of political economy?" &c. &c.

Again, he adds: "And if we mistake not, a similar policy is pursued in Massachusetts, and we believe has even been suggested in the legislature of this state.—Are the people in this country of intellect so obtuse that they cannot discover, without a bribe, those branches of industry?" &c. &c. pursuing the same strain of school-boy argument, for nearly half a column of his paper.

These, you will observe, are the editorial remarks of a paper, in general, as ably conducted as any in the United States; certainly enjoying the greatest circulation, and possessing, therefore, a corresponding influence. This editor probably does not imagine, that agriculture may be made a science; and would be surprised to hear that the very bounty he so rails at, has been already the means of saving more than its value in wheat, by causing a discovery, by which the destructive ravages of the *weavil* may be arrested.

The formation of county agricultural societies, is another powerful aid to agriculture. The combined efforts of these societies and the public press, would soon place agriculture in the high station among the useful arts, to which she is justly entitled. To effect this desirable object, I suggest, whether it would not be advisable that each county agricultural society, should appoint a suitable committee to awaken the public, through the public press, to the vast importance of agriculture to this country.

Pennsylvania, Ohio, and many other states, are far ahead of this state in the improvement of farm stock. The high price of the improved breeds, places them out of the reach of our farmers. This must necessarily be the case, while our great breeders are endeavoring to raise only the *pure blood*.

True policy dictates that we should obtain a good breed by *crossing*, while we at the same time, obtain the best breed from the pure blood.

The great improvement in our horses, was effected by carrying studs of blood, to "stands" through the country. The same course might be pursued with the improved breeds of imported bulls, Berkshire boars, &c. &c. In this way, the attention of our farmers would be led to improvement in breeds; they would be better enabled to appreciate the good breeds, and would thus gradually acquire a desire to improve their own stock. Breeders would thus sooner experience ready sales of the high priced stock, and would, I have no doubt, even benefit themselves, by establishing such stands *gratis*.

In the last November number of the Cultivator, your correspondent, Mr. John Bodden, of Poughkeepsie, states that nearly seventeen acres of his corn were destroyed by the grub worm, although the corn was soaked in saltpetre, which he observed had been stated in the Cultivator as a preventive.

On Long-Island, and in New-Jersey, a worm very similar to the grub worm, has been very destructive to corn for the last two seasons. As very little has been published in relation to this worm, and as it may be desirable to preserve a record of their visit among us, I will briefly describe them. In the month of May, 1837, this worm commenced the work of destruction in our corn fields. It resembles the common grub in size, colour, and general appearance; both are a light gray colour, with red heads. The grub has legs only near its head; this worm, however, is legged as a caterpillar: from head to tail. The grub has a rough, serrated skin; this worm has a smooth, glossy skin. The grub preys upon roots; this worm upon the stalk, under, though near the surface of the ground. In 1837, my corn was planted early, upon an old sod, which was so infested with this worm, that I was obliged, for more than a month, to go daily through the field, pulling out the worm and replanting the corn, where necessary.—In some cases, corn of the third and fourth planting, was destroyed by these persevering rascals.

Their presence in a hill is easily detected, by the withered appearance of the stalk eaten off by them.—The low and wet parts of the field were free from them, while the dry and sandy knolls in the same field, were overrun with them. They disappeared about midsummer. In 1838, they were less numerous. One of these worms ate through a stalk of corn three quarters of an inch in diameter, and two feet five inches long.—One of my neighbors says, these worms, about eighteen years ago, were as numerous and destructive as lately, and that they disappeared after a visit of two or three seasons. They were called, he says, *tiger worm*. Wolf grub, I think, would better designate their voracity.

With regard to soaking corn in saltpetre, my experience fully proves its efficacy as a security against birds. In 1836–7, tame pigeons and crows fattened upon my newly planted corn, despite of fowling-piece and scarecrows. In 1838, however, I soaked my corn, as you directed, in saltpetre, to quicken germination, and as a security against birds. To my delight I found that pigeons, crows, and barn-door fowls, left the corn unmolested; though they all, at first, tried to acquire a relish for saltpetre. And here it is but justice to say, that I have been remunerated twenty fold for subscription to the Cultivator.

I fear I have intruded too much upon your valuable columns. I will only add a question: Have you proved the short horned Durhams to be good milch cows?

By the bye this privilege of questioning, is no inconsiderable benefit to the patrons of the Cultivator, though it doubtless imposes on the kindness of the editor.

BROOKLYN.

Inducements for entering on Rural Pursuits.

Greenfield, Mass. April 2, 1839.

Mr. Editor—In speaking of the inducements that present themselves to young men, for embarking in agriculture, we cannot forbear saying a few words with regard to the pecuniary profits that are held out. We do this, not to feed that love of money making and money getting, in which most of our citizens seem all absorbed, and which we are almost ready to pronounce our country's greatest curse, but rather to obviate an objection that is often urged, that but a very scanty and uninviting livelihood is to be obtained from agricultural pursuits. And on this point, let not the profits resulting from the present system of farming be, by any means, taken as a criterion. The ignorance of our farmers, and their prejudices against improvement, preclude them from reaping more than a tolerable subsistence, and we think we do not exaggerate when we say, that our present agricultural products might be more than trebled, by a more enlightened and liberal system of culture. Besides, these products will always find a market. They consist of the necessaries of life, and so much greater, at the present moment, is our consumption than our production, that we are obliged to go abroad to find the wherewithal to feed our citizens. In this, as in every other pursuit, the profits must be in proportion to the skill, industry and intelligence of those engaged in it. The gains of the farmer cannot be rapidly acquired from the nature of his profession; they are generally not inordinate, as more capital is required for extensive agricultural operations than most men can command: but they are sure, and are amply competent for the wants of life, and all the luxuries and gratifications, that mind or body need demand. They are uninfluenced by the changes, that are engendered by the speculations of businessmen, and politicians, and, when restricted at all, are so by the ignorance or blunders of those dependant upon them.

But we wish to view the subjects from higher grounds than those of pecuniary interest. We find one of the greatest charms of an agricultural life in its perfect independence. The farmer's prospects stand unaffected by the many fluctuating relations of society, and depend, in a great measure, upon his single energy as directed to the operations of nature. His hopes and fears are not gauged by every breeze that blows in the mart, and the political arena. He feels, or ought to feel, that his pursuit is the corner stone of all others. He *creates* what the manufacturer works, the merchant barters and the ship master conveys to the different quarters of the globe. He draws from the bosom of the earth the very food of commerce and manufactures. And hence the dignity of agriculture. Its powers are creative, while most other professions are merely constructive. It elicits ten thousand products, that otherwise might never have existed, and which are remodelled in the hands of the mechanic, and converted into cash by the merchant. And this great independence of other pursuits cannot, we think, but create a corresponding independence of character in those engaged in agriculture. It must engender a freedom of thought and action, so desirable for mental development, and which is so often crushed in other callings, by their subserviency to each other.

We particularly admire the character and influence of rural pursuits. Very many, we know, view the farmer through the medium of the plough, the harrow and the spade, and make the most drudging details of his pursuit a criterion by which to measure his profession. For this, it must be allowed, there is in many instances too much cause. But we are urging the choice of an agricultural life on different grounds. It is the character of the men engaged in it, and not of the profession, that gives a dignity and weight to it. The most noble pursuit may be disregarded by the ignorance and baseness of its votaries, and the most humble may be elevated and dignified by education and intelligence. The culture of the soil is becoming a *science*, and one of the noblest of all sciences. Study and discipline are made its ground work, and the structure is raised on the most liberal principles, united with taste and refinement. Natural science in all its departments is made subservient to it. Chemistry, mineralogy, botany, vegetable and animal physiology, mechanics, &c. &c. are constantly in action in all its operations, and their practical application develops every energy of mind or body. New wonders are ever being disclosed, and the harmony of nature brought to view, and that excitement and interest, so necessary in all pursuits, is constant, high toned, and healthy.

We have already spoken of the unadulterated pleasure to be derived from rural pursuits, and we appeal to those who have had the advantages of experience, to correct us if we have advanced any thing beyond the truth in urging the choice of an agricultural life. We offer these imperfect considerations at this time for various reasons, and among others because we see a due sense of the importance of agriculture is beginning to be felt by the public, and a strong desire manifested to elevate its character, and we should regret that this desire should be disappointed from the absence of those, who might meet the wishes of the public. There is a want of pioneers in the cause of those who may disseminate the discoveries of science and the observation of others in the culture of the soil, and impress their utility on our whole farming population. If the public spirited intentions of some of our leading agriculturists are carried into effect in the establishment of an Agricultural School, an opportunity not to be lost offers to those of our young men, who are willing to turn aside from the dazzling visions of wealth and office to the more quiet but not less honorable and dignified duties of the scientific farmer.

H. V.

Proposed mode of Planting Corn.

Petersham, Feb. 26, 1839.

Mr. Buel—I have a piece of green sward which has been mown six years. I wish to take it up in the spring, and plant it with corn. The soil is a dry, stiff, yellow loam; and it has been the practice about here to plough the land both ways, and harrow it down; dung it in the hill and plant it. I told a book farmer in Hardwick, that I thought I should try the new way about planting time, to spread on a large quantity of barn yard manure, say twenty-five or thirty cart loads to the acre, as I have a plenty of it; then turn it over as slick as I can, roll it down; harrow it with a harrow that has short teeth, mark it out into rows both ways, and plant it. As soon as it is large enough to weed, to go through with the cultivator both ways, and then with the hoe, alternately; the gentleman told me that I should not be successful; that if it should prove to be a dry, warm summer, the sod would not decompose in time to furnish the food that the young plants require; that turning over a green stubborn sod with so much unfermented manure, it would firefang, and that the grub worm would be a great deal more likely to injure it, and he thought that I should have a very light crop. I should like to have your opinion through the columns of your paper.

I have another piece of one acre, the soil the same, which I wish to plant with carrots. Three years ago it was a clover ley. I spread on to it a very large quantity of manure two years ago, and ploughed it very deep, say twelve or fifteen inches; then crossed it and harrowed it; furrowed it out, and dunged it in the hill with fine manure, and planted it. I had a very great growth, but the frost came so early that I lost it entirely. Last spring I ploughed it, and it was very light; I sowed it with four bushels peas and oats, two thirds peas; ploughed, harrowed and bushed it, and it was perfectly pulverized like a garden; I also seeded it with timothy and clover. It all came up very fine; the oats grew very rank, and soon began to lodge. I had so much to do, that I let them stand too long, or rather lay, for it took three hands one day to mow them. The weather was bad, and I had to turn them three times. I had four very large loads of straw, and fifty-seven and a half bushels of grain; and I should think there was left on the field as much as ten or fifteen; but if you think this land would bear a good crop of carrots, I should like to know the best way of raising them. Respectfully yours,

D. C. PAIGE.

Remarks.—If the manure had been spread, and the ground ploughed last fall, it would have been better. But as it is, spread the dung and plough early; if the dung is unfermented the better. Do not plough *slick*, if that means a flat furrow, but lap the furrow-slices on to each other; and if the surface is horizontal, gather the land into ridges for three or four rows. If the furrows are lapped, and then well harrowed down, the injury and inconvenience from rain and from grass will be sensibly diminished. The dung, if spread, will not fire-fang, nor is much to be apprehended from the grub—which will feed upon the green matter turned under. The second piece of ground will be in good condition for carrots, though had the soil been more sandy it would have been preferable. See our directions for culture in another column. Will Mr. P. advise us of the result of his experiments?

Directions for making good Mortar.

Schenectady, 5th April, 1839.

Dear Sir—Until the Society for promoting Useful Knowledge, shall be in active operation, the Cultivator appears to be the proper vehicle.

Soon after the great fire in the city of New-York, in December, 1835, I noticed an inquiry in the Commercial Advertiser, "whether the art of making good mortar had been lost," as in the modern built brick buildings, the mortar "did not connect and adhere to the bricks." I wrote, and stated the former and modern method of making and using mortar, and it was published in that paper.

As inquiries on this subject are frequent, and as it is painful to see the impositions practised on those who employ builders, without knowing how to guard against deception, I will give the opinion I have formed, by long observation, and some practice in erecting buildings.

Formerly, hard burnt bricks only, were used for building houses. The bricks were put into a tub of water, kept on the scaffold for the purpose; and when saturated with water, they were handed by the laborers to the mason, who laid them into the wall. Walls made in this manner, when taken down, a crowbar and hammer must be used with force, to separate the mortar from the bricks.

It was noticed by persons who were present at the great fire above quoted, that some of the new brick stores then lately built on Exchange Street, when partly burnt, fell down; and the adjoining buildings, to which the fire had not extended, fell after them.

A few years ago, the six story brick store of Messrs. Phelps & Peck, on the corner of Cliff and Fulton-streets in New-York, fell down, and crushed several persons—an awful sight and calamity. I was in the city, and passed by the store, about one hour before the fall. It was observed, that the bricks separated from the mortar, as clean, as if they had not been laid in the mortar, and the mortar was fine, like dry sand.

Modern brick walls, are chiefly made, not of hard burnt, or what are called weather bricks, but what are called salmon, or half burnt, or imperfectly burnt bricks. These bricks are brought dry, and in some instances, *warm* from the kiln, and laid immediately in the wall. The moment such bricks are laid on the mortar, they absorb all the water from the mortar, as quick as a flash, leaving the mortar merely damp. The mortar when dry, will be soft, and the wall may be taken down with the hands, as there is no cohesion in the mortar. If the bricks are saturated with water, before they are laid in the wall, even such bricks of inferior quality, will make a tolerable wall, though not so strong as of hard burnt bricks.

This is the mode of erecting buildings all over the country, because a little labor and expense is saved, by not wetting the bricks. Too much mortar is often used. Enough to fill the seams and make a solid body, is best.

Those for whom buildings are erected, particularly in the city of New-York, in general, are as ignorant as children, of what constitutes the difference between good and poor walls. Placing perfect confidence in masons, carpenters, builders—as they do in lawyers and other professional men, they get a building for a little less money, and a very little less too; and in some cases, it falls down before it is finished and off the hands of the builders, when the walls are only of the thickness of the width of the bricks, as they frequently are, particularly when against another building, to hold them up.

Another fault is, in making mortar of loam or quicksand, (common in some places,) instead of clean and coarse sand.

One part of quick stone lime, and five parts of clean coarse sand, will make good mortar for brick or stone walls.

The masons object to much sand and little lime, because the mortar will be short and crumbly when used, particularly the over-head ceiling, but when so made and put on, it will be twice as hard as if otherwise made. The loam and more lime, make mortar much more easy for the mason for plastering ceilings. The quantity of lime wanted, is merely to fill the interstices, and make of the sand a solid body, for strength.

When masons want a winter's job, they will tell you that the mortar will *freeze dry*, and be as good as when laid in summer. Such masons, if honest, are not philosophers, nor will philosophers believe and employ them.

In the March number of the Cultivator, it is asked by a subscriber, "What is the best method known among our builders and mechanics, of protecting north-east brick walls, and generally, of keeping stone and brick walls dry." Hard burnt bricks, called clinkers, will not absorb water. If north-east walls are made of such, or covered with boards, water cannot penetrate them. But few persons understand the difference in the quality of bricks. Street pavements made of clinker bricks, will last an age and be dry, except while it rains.

Stone walls are liable to be wet, by condensing moisture from the air, when the atmosphere changes suddenly to a warmer temperature. Respectfully,

DAVID TOMLINSON.

Clover Machine.

Courtland, Ala. March 27th, 1839.

The re-appearance of a paragraph, in a late number of the Cultivator, describing the machine for gathering clover seed, used by M. L'Hommedieu, constructed with an open box and teeth in front, suggested to my mind the propriety of informing you of a trial made of one, made from the same description, published perhaps in the 4th volume. This experiment was a complete failure. The shafts were fastened to the ends of the axletrees outside the wheels, which were eighteen inches in diameter; which left the body completely under control of the driver, to be raised or lowered at pleasure, according to the growth of the clover. On putting the machine to work, the clover-heads and stalks, in a few steps, choked up the teeth, so that the driver was compelled to stop and relieve them; and this happened so often, that I determined to attach a revolving cylinder, with four steel knives, just above where the choking took place, according to a suggestion in the Farmer's Register. This cylinder was driven by a three inch band, running on a notch on the inside of the wheel, twelve inches in diameter. The addition was beneficial in some degree, but the original objection of choking continued to be so inconvenient, that the machine has been laid aside as a complete failure. Very respectfully,

JAMES E. SAUNDERS.

Rotation of Crops.

Putney, Vermont, April 6th, 1839.

Mr. Buel—Sir—Having been for some time a regular subscriber to the Cultivator, and having practised in the rotation of crops, for the last twenty years, I deem it a duty I owe to the public, to speak on the occasion—to add my testimony and experience to what has been published in your valuable paper. My farm is situated on the bank of Connecticut river, and is fast returning to that native purity and fatness, for which these lands were once noted. My land, in 1815, when it came into my possession, poorly paid for cultivation, owing to the successive croppings, without grass seeding, until it would not return a crop, and was left in common to diseases and mullin. I am thus particular, in order to show the downward course a farm will take, if there is nothing returned to the soil, by successive croppings. I commenced in June, 1815, to summer fallow my poorest land, and first of September sowed it to rye, and seeded it to Dutch clover, as the southern clover was not known among us then. I purchased one ton of plaster of Paris, which was just beginning to be used in this section of country—of which, I sowed a bushel or more upon an acre. I had a fair crop of rye. The next year I commenced another ten acres of fallow, in the same course. My clover did well on the first piece. I sowed another bushel of plaster of Paris in April, after I took my crop of rye off—and first of July, I ploughed under the clover, and a heavy job it was. In September, I ploughed it again, lightly, and sowed it to rye, and seeded it to clover and herds-grass. The next year I mowed it—the next year, I planted it to corn; and the next year I sowed it with oats. My next crop was rye, and seeded to clover as before. At the same time, I was bringing up other lands in the same way, and with equal success, until I had brought all my farm into this mode of cultivation. For the last ten years, I have left out the crop of rye, as not so profitable a crop—and left my land heavier, and adopted a three course system, which I think is the better way. I have only to sow my oats early, in order to seed clover, which takes surer and better when sown early than late. I have used plaster of Paris freely on my grass crops and corn land. I use a roller on my oats, as I always have seeded to clover all my small grain crops, which I think much of, both for seeding and rolling down the ploughing before planting. I use the southern clover, which is much the best for rich land in the rotation of crops, as you get the first crop for hay, and of a better quality than the Dutch clover, and the second for seed, which is a clear profit, and a good one this last year, as it is worth twenty dollars per hundred pounds, and 200 lbs. is our average crop.

I use my manure in its green state, and plough it under as soon as possible; as I plough all my planting land, and plant as soon after as possible, I am not troubled with worms but little. When I mow but one year, I prefer planting early, and much thicker than is generally practised.

My experience in making manure, may be worth communicating, as it is to me an important branch of agriculture, and should excite the energies of all farmers. I have yards attached to my hog-houses, that the hogs may go in and out at leisure; these I keep supplied with soil, loam, or muck from swamps, with a good quantity of straw, or litter from the barn-yards, which every good farmer has for the occasion, from which, by care and some labor, almost any quantity of manure can be made, and that which is good. I have only to add soil, weeds, straw, green clover, summer manure, or any, or every vegetable substance, as all are acceptable to the hogs, who are very industrious, and will manufacture more manure in value, than their expenses in keeping. I feel that my position is good—that my lands are continually increasing in fertility. If any of it flags, or decreases in richness, I have only to plough in a crop of clover, and it immediately takes its place among my richest lands.

Thus you will readily see, that where lands will produce clover, by the aid of plaster, there is no trouble in raising land to a high state of cultivation. I have always returned to my lands all my crops, except my grain, which I market, except what is needed for farm stock &c. With much esteem, THOMAS WHITE.

Curing Hams.

Hanover, Mich. March 7, 1839.

JESSE BUEL, Esq.—Sir—Having had the perusal of your valuable paper from the commencement, I beg leave to present to the public, through its columns, my manner of preserving hams. I turn my barrel over a pan, or kettle, in which I burn hard wood, (commonly hickory or maple,) for seven or nine days; keeping a little water on the head of the barrel, to prevent it from drying. I then pack two hundred weight of ham in my barrel, and prepare a pickle, by putting six gallons of water into a boiler, with twelve pounds of salt, twelve ounces of salt-petre, and two quarts of good molasses; this I stir sufficient to dissolve the salt, &c. and let it boil, and skim it. I then let it cool, and pour it on my ham, and in one week I have smoked ham, very tender, of an excellent flavor, and well smoked. When the weather becomes some warm, there will a scum rise on the pickle; by keeping my ham under the pickle, it will keep the year round.

N. B. It is better to have a *good* white oak barrel than any other. Try it, and if you ever have had meat smoked earlier after killing, and more palatable, please inform the public through the columns of your paper, and oblige a subscriber. Yours, &c.

H. FOWLER

JUDGE BUEL—Dear Sir—I send you a copy of the within directions for using urate and poudrette—if you are of the opinion it is of sufficient importance to the agricultural interest to publish it in the Cultivator, you will do so. I think highly of it myself, and intend to make some experiments on it in the ensuing season, and propose to submit the results to you for publication.

Very respectfully, your most obedient
A. DEY, 63 *Cedar street.*
New-York, 7th March, 1839.

Urate and Poudrette.

The attention of the public has recently been directed to the use of *urate* and *poudrette.* It has long been known in France, as the most efficacious of all manures, and the few experiments made the last year (1838) in the use of *poudrette,* in and around the city of New-York, has awakened the attention of farmers and gardeners. The Royal Academy of agriculture in England have caused experiments to be made of the respective power of the different manures, and upon the trials so made it appears beyond a doubt, the superiority of manure, made from sinks and privies, over any other productive agent for agricultural purposes.

DIRECTIONS.

The following directions are given by *Peter Barthelemy,* (who was one of the first discoverers, in France, of the present system of preparing the articles,) how and in what manner it should be applied, and who recently has introduced its manufacture in the city of New-York.

Urate is the product of the *liquid* part, and *poudrette* of the *substantial* part of sinks, or privies, both of them reduced by different processes, to a dry and inodorous substance, and used as the best of all manures known to the agriculturists or horticulturists; *being animal manures of the richest kind, and the most powerful of any application that can be made to the earth.*

URATE.

The urate may be used in its dry state by spreading it on the land as you would lime or ashes, *or* after having been dissolved in water, may be used through a watering pot, or by a cask, on cart wheels, in the same manner as the streets in the city of New-York are watered in summer.

For all kinds of small grains, such as wheat, rye, oats, barley, flax, and others of a like kind, it may be sowed dry, upon the soil in the proportion of 12 to 18 bushels per acre, according to the quality of the land.

For *corn* and *potatoes*, and such like, it is best to mix the urate in an equal quantity of dry soil, and put in the hill about a gill, or handful, sprinkled round the seed corn and potatoes, as is usually done with ashes.

For beets, turnips or other vegetables, sowed or planted in drills, the urate is to be prepared in like manner and sowed in the drill.

For grape vines, fruit trees, forest trees, flowering trees, flowers; also for garden vegetables, such as cauliflower, cabbage, melons, cucumbers, and the like, *urate* is dissolved in water, in the proportion of one pound to a gallon of water, and poured on the subject; *one application* is sufficient: and for articles not herein enumerated, it may be sowed dry on the surface of the ground.

Where the land retains water, during the *winter, urate* must be used only in the *spring,* in order that its salts may not be absorbed in too large a quantity of water.

Where the land is dry, or does not retain water, during the winter, *urate* may be used in the autumn; if however the sowing takes place, shortly before the hard frosts, it is better to use urate only in the beginning of spring.

As a *general rule,* more urate is required upon the same quantity and quality of land in *autumn,* than in the *spring,* if used in the *spring* it is better to apply the urate in a damp day, or immediately after a heavy rain, if it cannot be applied shortly before the rain.

There is a great advantage in *soaking corn* or other *grain for one hour only* in a strong solution of *urate* before planting or sowing it, the corn or grain will *start sooner,* be stronger and less liable to attack by worms or birds.

POUDRETTE,

Is to be used, in the same manner as urate, with the following exceptions, namely; the *quantity* must vary from 18 to 35 bushels per acre, according to the quality of the land, less than 18 bushels to the acre may not be very satisfactory, and more than 35 is useless.

Poudrette is never dissolved in water before being used, as is urate, but in other respects, it is used, in its dry state, or by mixing it with dry soil in hills or drills, or sown broadcast, as lime or ashes.

The difference of the season, between spring and autumn, and the state of the atmosphere are to be considered, before using either urate or poudrette; damp weather is always to be preferred. Neither of them contain any seed of weeds of any description; an application of urate and poudrette once in every three years is sufficient.

Urate and *poudrette* may be sent to any part of the country in barrels or bags, barrels to be preferred, when it is liable to get wet. Orders may be given, post paid, directed to "*The New-York Urate and Poudrette Company,*" *Box No.* 1211 *post-office, New-York.*

The urate and poudrette, made by this company is not confined to distribution among its stockholders only, and therefore farmers and gardeners may expect a supply in the order in which their application is made without any condition of becoming a stockholder, or advancing any more money than may be sufficient to purchase what they need.

The public should be on their guard in relation to the use of the poudrette, as it is feared, it may be brought into dispute by other manufacturers of the article, where quantity, rather than quality is considered most desirable.

It may be that on trials of urate and poudrette, a different application may be found more desirable; in such case it is hoped the experimenter will make known to the public his discovery.

FURTHER TESTIMONY.

Dr. Granville, in his report to the Thames Improvement Company, in speaking of the immense source of agricultural wealth which the sewers of London afford, but which is now worse than lost, makes the following statement of facts furnished by them.

If a given quantity of land sown, and without manure, yields three times the seed employed, then the same quantity of land will produce 5 times the quantity sown, when manured with old herbage, putrid grass or leaves, garden stuff, &c; 7 times when manured with cow dung; 9 times with pigeon's dung; 10 times with horse dung; 12 times with urine; 12 times with goat's dung; 12 times with sheep's dung; and 14 times with night soil, or bullock's blood. Or in other words, an acre of land sown with two bushels of wheat, without manure, will produce 6 bushels; 10 bushels with vegetable manures; 14 bushels with cow dung; 18 bushels with pigeon's dung; 20 bushels with horse dung; 24 bushels with goat's dung; 24 bushels with urine; 24 bushels with sheep's dung; and 28 bushels with night soil, or bullock's blood. But if the land be of such quality as to produce, without manure, 5 times the sown quantity, then the horse dung will yield 14, and the night soil $19\frac{2}{3}$ the sown quantity; or land that will yield without manure 10 bushels an acre, manured with horse dung will produce 28, and with night soil about 39 bushels of wheat per acre.

These results, and multitudes of recorded experiments, prove that they in no case vary far from the facts, show the immense superiority of night soil, or Flemish manure, over any hitherto employed. In addition, Dr. Granville found that some crops which yield large profits, and are so extensively cultivated in Flanders, can only be obtained in abundance, and of the finest quality, by employing what may emphatically be termed Flemish manure in the preparation of the soil.

Another important matter in the comparative value of manures, and of essential practical interest to the farmer, has been established by the same authoritive investigations; and that is, that while night soil has produced fourteen times the quantity sown, where horse dung has yielded only ten—the proportion of the former, or Flemish manure, was, to the horse dung employed, only as one to five; so that with one ton of the Flemish, a larger produce was obtained than with five tons of the best stable manure.

Defence of the American Society for the Diffusion of Useful Knowledge.

CONCLUDED.

This communication has already reached such a length, that we shall say but a very few words, on the only other subject, which we proposed to touch; the character of the published library.

Your correspondent observes, "Many of the volumes are excellent works in their way; but most of them are not adapted to the capacities of the young;"—and your own remark is, that they are "wholly unsuited to form the *basis* of a common school library for an agricultural population."

The circumstances under which that library was published, have been mentioned; and it is only necessary, to refer you to what has already been said, and to remark here—that the library published, was never offered as specimens of what the society proposed to produce in the way of school libraries; such libraries, as the society well knew, could not be produced without the means requisite to employ capable men in producing new books, and re-modelling old ones.

As to the character of the books—we think an examination of them, will show many of them to be intelligible and interesting to the most youthful readers at our district schools, and scarcely one above the capacity of the elder pupils. The objections too, that are made, are not for any bad qualities which the books have, but for the absence of certain qualities which they ought to have possessed; no one has denied, that the books are valuable as books, but they are not considered as possessing all the qualities which should be found in such publications. We could add more than this negative praise; we could mention those, whose names have added lustre to some of most lofty stations both in our state, and in our national governments, who have examined the published library, and have given it their most unqualified approbation. But we have no wish to discuss the character of those books; they are before the country, and the people may judge for themselves. All that we ask, is, that the library may be judged with reference to the circumstances under which it was prepared: that the motives which led to its publication may be appreciated; and that it may be considered not as a *basis* of a common school library, but as a commencement of a new undertaking, made under peculiar difficulties, prepared to meet a peculiar emergency, which would not admit delay.

We make these statements, not, from feeling that our conduct calls for justification; but, because we are not willing, that a combination of means, the result of great labor, and capable, as we believe, of effecting great ends, should be rendered useless, by a misconception of our proceedings, or a misconstruction of our motives.

We embarked in this cause, under a sense of duty; we have devoted to it money, time, and labor, under a feeling that we were bound to do what we could to supply the great want of our country—a want, which every reflecting man sees, and every good man desires to remove. We have, after much exertion, provided means, which we believe, if carried to perfection, will be commensurate with the great objects we wish to effect; we shall proceed in using our utmost powers in perfecting those means; and should we fail, however much we may regret not having accomplished what we had hoped for our country's good, we will have the satisfaction of having done our duty in this great matter, and will have relieved ourselves from all responsibility for our failure, by having done all we could to ensure success.

But we shall not fail. An interest in education, has always been a predominant one in the minds of the American people: and every day are we receiving from different quarters of our country, encouragement to go on in the work we have undertaken. Arrangements are making, which will soon produce a library possessing those qualities, which the inauspicious state of the times, prevented our giving to the first series; and the benevolent and the patriotic, are responding cheerfully to our applications for pecuniary aid.

We call upon every lover of his country, to aid us in our undertaking; we ask him to examine for himself, whether the measures we have adopted, are, or are not adapted to the ends we propose; and should there be any thing erroneous, or any thing defective in our plans or proceedings, we ask his friendly counsel and advice, and while he corrects our errors, to do justice to our motives: But should he find, that the means we have selected, are well calculated to elevate the character of our national education, and to extend its limits, we do not solicit as a favor to ourselves, but rather demand, as a duty to his country, to his children, and to himself, not to stand an idle spectator of our proceedings, still less, to throw obstacles in our path—but to exert to the utmost the powers which God has given him, whether talent, wealth, or influence, in co-operating with us in the great enterprize of extending the benefits of sound education throughout our whole land. *New-York, March 1st,* 1839.

EXTRACTS.

[*From the New-England Farmer.*]

We proceed in the publication of Premium Farm Reports—intending to give them to the public with as much despatch as the state of our columns admits. They will be read, we are pursuaded with much interest. We give them without regard to any order, as is most convenient; but we shall very soon wind off the worsted. The subjoined account is from Mr. Fay, in Southboro', who received a gratuity of fifty dollars. H. C.

A SCHEDULE OF PETER FAY'S FARM, SITUATED IN SOUTHBOROUGH, IN WORCESTER COUNTY, MASS. 1838.

Question 1. Answer—one hundred and fifty acres.

2. It consists of loam, gravelly loam and gravel, and under the stratum a clay gravel.

3. The best method of improving my land—the *plough* is decidedly the best.

4. I till about eighteen acres, and I put twenty-five loads of manure to an acre on that which I plant with corn and potatoes.

5. I apply it both in its long or green state and in compost.

6. I do both spread and plough in the manure put upon fields to be planted with corn and potatoes, and also put it into the hills.

7. My method of cultivating green sward is by ploughing it at any part of the year, and of frequently harrowing the same the year previous to its being planted.

8. I mow from thirty to thirty-two acres of upland, and averaging two to two and half tons to an acre,

9. I irrigate about four acres, commencing about the first of May, and allow the water to flow about one month, and I think I get about one-fourth more in quantity, and the quality not as good.

10. I do manure the land that I irrigate, and a part of my other land that I mow, once in two years, and I put twelve loads of compost manure to the acre.

11. I have mowed about ten acres of land not suitable for the plough, and the quality of the hay very ordinary, and producing more than five tons upon the same the present season.

12. My method of reclaiming my low land has been to dig out the stones and then to smooth or level the same, and give it a top dressing of loam or gravelly loam or gravel and then compost manure, and by seeding of herds grass, red top or clover, and roll in the same. On bog or peat meadow I never have performed any operations.

13. I have planted nine acres of corn the present season; my method of preparing the ground has been, of ploughing the same fine in the spring, then harrowing it, then carting on my manure and spreading it, then ploughing in the manure fine, and then rolling the land where it will admit, if not bushing it. Six acres of it I have cultivated in this way, by putting ten loads of long or green manure to an acre, and fourteen loads of compost manure in the hills, and planted the same in hills three feet and six inches apart each way. And on the three acres in addition to the ten load of long or green manure to an acre, I spread fifteen loads of compost manure to an acre, by putting the loads between the long or green manure, and ploughing in the same, and not manuring it in the hills; hills four feet and six inches apart from east to west, and three feet apart from north to south. I soaked about one half my corn in water about twenty-four hours and rolled the same in gypsum; the other half I planted dry without any preparation. When I planted my corn I put a table spoonful of gypsum into each hill, and when the corn had come up I put six bushels of wood ashes, lime and gypsum around the corn upon the hill, in the proportion of one half ashes, one fourth lime and one fourth gypsum to an acre upon the said nine acres. I used the cultivator instead of the plough among my corn and hoed the same three times, and made the hills of a small flat form.

14. I have planted five acres of potatoes the present year, four acres of which I ploughed the land fine in the spring, then harrowed it, ploughed it the second time fine, then spread twenty loads of compost manure on the acre and harrowed it in, furrowed the ground four feet and six inches apart north and south and three feet apart east and west, and planted them the first week in May, when the ground froze every night, and on the north side of the wall the ground did not thaw through the day; when I planted the potatoes, I put a table spoonful of gypsum into each hill, and when the vine made its appearance through the ground, I put twelve bushels of wood ashes, lime and gypsum on the hills in the proportion of one half ashes, one fourth lime, and one fourth gypsum; I ploughed and hoed them three times. The produce was one hundred and sixty bushels to the acre. The kinds, a part of them a red potato called among us here the Rutland, and a part of them were the blue potato: the soil a gravelly loam.

The one acre was a green sward ploughed in about the middle of May, this spring, then harrowed the land and spread twenty-five loads of long or green manure to the acre, and planted it in rows three feet and six inches apart each way; ploughed and hoed the same twice: the soil was a gravelly loam: the produce one hundred bushels to the acre. The hot and dry weather in the month of August, was very severe with my potato crop upon both fields, and the product not half of an usual crop. The kinds of potatoes were the same as planted upon my other field.

15. I have among the corn in one of my fields of about three and a half acres, the English turnip, where my corn was very much injured by the cows, and the growth is extremely promising, but I have not harvested them now.

16. None this year of winter grain; of spring grain three acres and three quarters. The ground was prepared by ploughing it fine, then harrowing it; then cross ploughed it, then rolled it, sowed the grain and got it in with the cultivator; put no manure upon my land in the spring; the land the season previous having been planted with a potato crop, sowed two and a half bushels to an acre. My grain was all of wheat of the Black Sea kind, except one half bushel, and that was of the Italian: the soil of a gravelly loam of a hard pan bottom: my method of preparing the grain was by washing all the foul seed therefrom, then put the grain into baskets and let it drain until dry, then put the grain into tubs and soaked it in as strong a solution of salt and water as could be made to dissolve in the water at a heat of one hundred and twenty degrees, and soaked the same ten minutes, then took it out upon a floor and raked in as much of dry lime as would adhere to the grain. When the grain was up about three or four inches in height, I sowed eighteen bushels of wood ashes, lime and gypsum in the proportion to one half ashes, one fourth lime and one fourth gypsum to an acre; this dressing is highly valuable to the wheat crop and to the succeeding crops of grass, and visible for a number of years, and one of the cheapest and best manures used.

The half bushel of Italian wheat was sowed upon the same field side by side of the Black Sea wheat, and the same process of preparing the land and seed was had as with the Black Sea wheat, and the produce was about the ssme with the Black Sea wheat, and the crop when ripe for harvest was one week later than the Black Sea wheat. The crop of both kinds was twenty bushels to an acre, and the last year I raised thirty-five bushels to an acre of the Black Sea wheat; my wheat was sown the last week in April.

17. I have laid down three acres and three fourths of an acre to grass the present season; I sowed the seed on the first day of May; my usual practice of seeding is, half a bushel of herds grass, one peck of red-top, and ten pounds of clover seed to an acre, and I sowed the same quantity this year; and was sown with the grain crop after the grain was got in with the cultivator and then rolled in.

18. The means and manner of collecting and making manure, are from my cattle and hogs, and by digging the loam out from under my walls; where I new set them or make new walls; the loam and sand beside the roads and from loam pits in my pastures, and the same carried into my barn yard.

19. I keep six oxen, twenty-six cows, no young cattle, two horses, sheep none. One of my barns is 84 feet long and 30 feet wide, one other barn 50 feet long, 36 feet wide, and 20 feet posts, and a cellar under two thirds of the same; one-third part of said cellar occupied for my hogs to lie under in the winter. Manure not covered.

20. My cows are all of the native breed.

21 I have raised no calves. I have fatted all my calves for the market this year and for several years past; I have fatted 37 calves for the market this year, which have brought me at my house $317; but I am convinced that I am pursuing a wrong course, and I intend to raise ten or twelve of my best calves yearly in future.

22. Of butter I have made up to the 15th day of October the present year, twenty-five hundred pounds, and of cheese only for my own consumption, six hundred and fifty pounds of two meal and four meal, and none of new milk.

23. Of swine I have on hand three old ones and twenty-two pigs; I intend to fat the three old ones and seventeen of the pigs, and keep five of the pigs through the winter for breeders; my swine are all of the native breed, and I make my pigs weigh on an average at ten months old, when dressed for the market, three hundred pounds, and have for many years past. I fatted seven thousand one hundred pounds of pork the last year, and sold six thousand and five hundred pounds of the same, which brought me six hundred and fifty dollars.

24. I feed my swine through the summer upon the skim milk and whey from my dairy, and give them no meal in the summer: I fat them upon corn and potatoes; I boil my potatoes and mash them fine and make the composition in the proportion of one bushel of potatoes and half a bushel of meal, and keep my hogs dry and warm, and keep them well littered with straw, which is of the utmost importance in the fattening of hogs.

25. I have a yard in front of my barns, 100 feet in length by 75 feet in depth, where my cattle and swine all yard through the summer and winter; and I get from 300 to 400 loads of manure a year from the same, meaning all that I make of long or green manure and of compost. The materials are of loam, sand that I cart into the yard in the autumn after I have taken the manure out, and of meadow hay, straw and corn stover that I throw out into my yard for my cattle in the winter for them to pick over. It is decidedly the best way that cattle and swine be yarded together for the making of manure.

26. I employ upon my farm three men for eight months, commencing on the first of April, and one man in the winter, and one man three months by the day: I have paid fourteen, sixteen and seventeen dollars by the month for the eight months, and from five to six shillings by the day, and boarded said men.

27. I have five hundred of engrafted apple trees and from two to three hundred trees not engrafted

28. I have forty two pear, 35 peach, 25 plum, 14 cherry, 8 apricot, and 4 almond trees.

29. My trees have never been attacked by the canker worm, to my knowledge; the borer has destroyed one apricot tree and four or five apple trees; I have not taken any means to destroy them.

30. I do not use any nor allow any ardent spirits on my farm, and have not for the last five years.

Horticulture.

[*From the Northern Journal.*]

Mr. CLARK—Observing that you occasionally devote a column of your Journal to the interests of agriculture and horticulture, I am disposed to give some of my notions and experience upon the latter; and if you think them *paper* worthy, you are at liberty to give them an insertion.

I have long been satisfied that our country gardens lose much of their interest and utility, by the unskilful and slovenly manner in which they are usually managed. Not only are they suffered, through shameful neglect, to be overrun with all manner of noxious weeds, but the garden vegetables are planted or sowed (as the case may be,) in such a crowded manner, that it is physically impossible that they should ever approximate to within 'gun-shot' of perfection.

Onions, parsnips, and carrots, should be sowed in drills, lengthwise of the beds, at least twelve inches apart, nor should they be suffered to remain too thick in the drills. Beets should be sowed in the same manner, with the exception, that the drills should be made twenty inches apart, and the plants six inches in the drills. Marrowfat peas should be planted in double drills, three and a half feet apart; and dwarf marrowfats in double drills three feet apart; while melons and cucumbers should be planted in hills at least seven feet apart each way, and no more than three plants should be suffered to remain in a hill.

By adopting the rules, as I have just stated, and keeping our gardens clean by often stirring the ground, we should add much to their beauty, and still more to their utility. It requires but a very small piece of ground, properly managed, to furnish in great variety a full supply of garden vegetables, which not only add much to our table comforts, but are eminently conducive to health; without which, life can scarcely be considered an enjoyment. But I must not stop to lecture or moralize; but, adding a little of my experience the last season, in support of my theory, I will close this communication, which I fear will be too long before I have done with it.

About the middle of May, I planted a part of my side border next to the street with cucumbers. The ground had formerly been thrown up and used as a hot-bed. Owing to the continued wet and cold, one solitary plant made its appearance; nor did this, until near the middle of June. But it did not lose much time after it was up. About the first of July, it commenced giving off its branches, and in less than a month from this time it completely occupied a space of six feet by ten, and scores of young cucumbers might be seen at a time, in different stages of development. Seeing it was a plant of great promise, I conceived the idea of keeping an account of its produce, and thought I should get two hundred; instead of which, I picked with my own hands, rising of four hundred as perfect cucumbers, from this one plant, as was ever set upon a table, or put into a pickle tub.

The circumstances which led to this astonishing result, were obviously, the high culture, the kind of cucumber, the uncommon fecundity of the season, and last, but not least, the ample space allowed to this plant.

It may not be improper to remark here, that many of the branches passed through the pickets into the street, and were fed off by the cattle. Others passed over into the walk, and were trodden under foot—and I will add to these, the untimely frost which happened on the morning of the 4th of September, which killed more than half the leaves—all of which operated as so many drawbacks, but for which, I have no doubt, my crop of cucumbers from this solitary plant, would have been augmented to 500! The greatest number I picked in any one day was 35—the greatest number in any three successive days 72. The length of the cucumbers when picked would range from 2½ to 3½ inches; and with the exception of a dozen or so, at the close of picking, were perfect in shape, and without spot or blemish.

I am well aware, that such a result cannot be reached except in highly favorable seasons; but then it should be remembered, that good seasons ever are lost upon us when the culture is bad; and that good culture will do much in supplying the defects of an indifferent season.

If the above remarks and detail of facts, thus hastily thrown together, shall have any influence in improving the state of our gardens, I shall feel myself amply rewarded for the trouble I have taken in placing them on paper.

DAVID PERRY.

Lowville, 16th Jan. 1839.

Extract from an Address of the Hon. JAMES M. GARNETT, *before the Fredericksburgh Agricultural Society, Va.*

The scripture injunction "*seek and ye shall find,*" is eminently true, not only of spiritual knowledge, but of every species which human beings are capable of attaining, and to no class of mankind is the frequent repetition of this most momentous truth more necessary than to ours; for the worst of our besetting sins is an overweening confidence in our knowledge of husbandry, and the consequent neglect of all the means essential to its improvement. Our secluded country lives, if long continued without interruption, serve only to cherish and confirm this self conceit, almost beyond all hopes of cure. The symptom which usually indicates this disease, in its most inveterate state, is, when the infected person is found, whenever an opportunity offers, constantly and most complacently, talking about "*his* method, *his* system."—When the disorder appears in this aggravated form, a recovery very rarely occurs, for there are only two modes of cure, and both of doubtful efficacy. The first is, to persuade the sufferer, if practicable, to go a little from home, and examine *other men's methods and systems;* for he will then surely find, either that *his*, upon which he has prided himself so much, as sole discoverer and practitioner, have really nothing new in them, or that they are much inferior to the methods and systems of many other persons of his own profession. The second remedy is, to tempt him to read (provided he can,) a few scraps or whole articles in print, about husbandry. If well selected, they may possibly coax him on to peruse a pamphlet, or book or two, on the same subject, when he will discover that the great bug-bear which he has always despised so much under the name of book-farming, is, in reality, neither more nor less than a well authenticated record of the best practices in every branch of husbandry, from the earliest ages to the present day. It is true, that he would find some mere speculations—some useless trash; but what books except the Bible, were ever yet exempt from these defects?—Yet, even the most illiterate believe books to be absolutely necessary to the perfection of every honest trade, profession, and calling under the sun. Strange then, most strange would it be, if *that* calling, upon whose prosperity even human existence itself depends, should be the only one which can prosper without books! The vainest fool that ever lived, if he were not an absolute idiot, would not fail to admit this, provided you could prevail on him to think long enough to form an opinion. How shameful—how disgraceful then is it, that any of our fraternity who are certainly *not fools*, should ever be found among the idiotic declaimers against the study of books on agriculture! This study would put him in possession of *one fact*, which of itself should suffice to animate his professional exertions for the rest of his life. It is, that all the greatest benefactors of mankind have been either practical agriculturists, or the devoted friends thereof—that they have deemed agriculture not only an *art* but a *science*, to the perfection of which the study of books is indispensable; and, moreover, that to the end of time, it will always fall so far short of perfection, as to leave ample room for constant improvement, even to the wisest and most experienced of our profession. To strive therefore with might and main after this improvement, and with a zeal and perseverance proportioned to its importance, should be deemed the indispensable duty of every man who presumes to call himself a friend to the great, the vital cause of agriculture. All who give it only *lip service*, should be ranked amongst its worst enemies, since the tongue alone is worse than nothing, unless the heart, the hand, and the purse, unite in its promotion: nay, more, unless this union, in the case of us Virginians, should so work as to obtain legislative aid to our cause. But no man in his senses can hope it, as our legislatures are now constituted, if he judges by their undeviating neglect of agriculture, from the end of our revolutionary war to the present time; although strange to say, a large majority of them have always been agriculturists! Of this there can be but one even *probable* explanation; it is, that they must believe *party politics* to be much more deserving of their patronage than *agriculture*.—To cure them of this hallucination, there is only one remedy, and *that*, thank God, is still in our power, although there is some doubt whether we shall all be sufficiently alive to our own interest to apply it. This remedy is, either to elect no more representatives, without clear, unequivocal pledges to do something for agriculture; or to instruct all who will not give such pledges, that they *must* do something, or never again expect our suffrages. Why this course has not been pursued, after so many fruitless and deeply mortifying applications to our legislatures, is to me utterly inexplicable, but upon the supposition that the majority of us are stone blind to the obvious means of relief; or that those who *can* see them, and are fully aware of all their momentous bearings, want the courage and perseverance to combat that fearful and most formidable obstacle to improvements of every kind, which consists in a union of ignorance and asinine indifference relative to our best interests. We agriculturists *may*, and often *do* live so comfortably at home, by industry and frugality, almost in spite of government neglect, nay, even of government hostility, that we remain ignorant of the vast extent to which legislative enactments have benefitted agriculture in other countries, and might advance our own, if we would only exert over them *that* influence, *that* control, which our constitution has secured to us. Should we much longer neglect to do so, all argument, all persuasion, used for any such purpose, will be as entirely thrown away, as an attempt to show how a dead man's life might have been saved, had a certain nostrum been administered while he was alive. Unless we mean "*to give up the ship*," in other words, to abandon our good old mother, Virginia, to her aboriginal inhabitants, the bears and wolves of the forest, and flee to "the far west," we *must* insist upon the establishment at public expense of a board of agriculture, or an agricultural school, or an agricultural survey of the state, or all three together. One or all of these means are indispensably necessary, if we would maintain among our sister states, that relative rank and importance to which our soil, climate, natural resources and population, so justly entitle us. * * * * * * *

Poudrette.

Mr. Minor, manager of the poudrette establishment at New-York, has furnished us with the following extracts, from highly respectable farmers, demonstrative of the great value of this new species of manure.

Extract of a letter from Dr. Josiah Bowers, dated Smithtown, Long-Island, 14th Jan. 1839.

"I have used poudrette on several crops with very satisfactory results. On one-half of a field of corn containing six acres. I applied it at planting time, at the rate of *one gill* to the hill. The produce was more than double that of the remaining half of the field. It is proper to remark that the soil was clayey and cold, and not calculated to produce good corn without warm manure. One-half of another field of ten acres, was planted with a gill to the hill; the next day the remaining five acres were planted without manure. Both parts came up equally well, but that treated with poudrette, very greatly excelled in rapidity and vigor of growth, being at least twice the size of the other, at the time of second hoeing. At this period, I treated the remaining five acres, with the same quantity of poudrette per acre as had been put in the hill of the first, sowing it on the ground at broadcast, and working it in with the cultivator and hoe. The result answered my expectations. That manured in the hill maintained its superiority for a few weeks, but it became daily more obvious that its rival was gaining upon it, and at the time of cutting up no difference could be perceived in the crop, both being excellent for the season. Forty bushels per acre on ruta baga, produced a result beyond my most sanguine expectations. A large number of experienced farmers examined the crop on the ground, and agreed in pronouncing it the most abundant they had ever seen.

"In the garden it was no less effectual, producing the finest melons, squashes, cucumbers, peas, beans, &c. Indeed I consider it peculiarly suitable for all annual plants, or such as require a rapid and vigorous growth. In addition to my own experiments, I have been careful to observe its effects, as used by my neighbors, as well as to ascertain their opinion of its value, in comparison with other manures. The best evidence of the high estimate they put upon its value, is the extreme solicitude manifest in all who have used it, to secure to themselves a future supply. J. BOWERS."

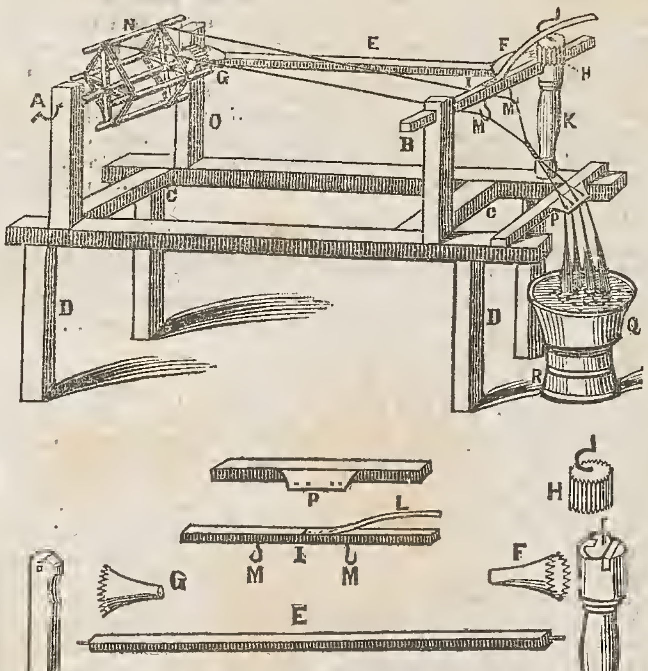
Extract from a letter written by Wm. F. Blydenburgh, Esq. dated Smithtown, L. I. Jan. 29th, 1839.

"To D. K. Minor—Sir—I have used poudrette in the hills of Indian corn, say a gill or handfull to each hill, with very decided benefit. The corn in the same field, manured in the hill with first quality hog-pen manure, for the first 60 or 90 days, appeared to be inferior to that treated with poudrette, at least 30 per cent; but at gathering time, little or no difference in the produce was perceptible. The quantity of hog-pen manure, put in each hill, must have exceeded the quantity of poudrette 600 per cent, or more. I should prefer, for the purpose of manuring corn in the hill, one bushel of poudrette to six of the best hog-pen manure.

"During the first thirty days, after the corn above named was planted, I would remark, that the part of the field treated with poudrette, appeared at least fifty per cent better than that treated with hog-pen manure. The beneficial effects of poudrette upon all spring crops are immediate, so far as I have observed. On grass lands, in the month of May, it has a decidedly beneficial effect, as a top dressing. I should think twenty bushels to the acre on grass, would double the crop, for one year; but the effects on that crop, for the second year, I should deem very slight. So far as I have been able to make up an opinion as to the value of poudrette, I should say a bushel of it is worth 12 bushels of street manure, 7 of horse manure, 6 of hog-pen manure, 3 of ashes, 14 of cow-yard manure, and ¾ths of a bushel of *ground* bones, for any crop, allowing all of them to be on the farm, or at least near to it, so that no freight is to be charged on either. When freight and cartage are to be considered, the difference in favor of poudrette, bating bones, is greater. I should be glad to purchase this season, 1,000 bushels of poudrette, at 30 cents per bushel. In fact, rather than not have it, I would give something more. W. F. BLYDENBURGH."

Piedmontese Silk Reel.

[Fig. No. 12.]



The frame is 6 feet 5 inches long, 4½ by 3 inches thick. Distance of the upright posts A and B, 4 feet 4½ inches.

C, C, length of the connecting bars of the frame, 20 inches in the clear.

D, D, legs, 2 feet 3½ inches long.

E, E, shaft, with the cogs at each end. Cog F has 22 teeth: cog G 25 teeth.

H, cog of 35 teeth, with a crank on the top, 4 inches sweep; point of the crank ¾ths of an inch from the edge of the cog.

I, a moveable bar, 2 feet 10 inches long, ⅝ths of an inch wide, ¾ths of an inch thick, playing through the upright posts B, K.

L, an iron carrier, of wire No. 1, one end fixed to work free, by a screw in the moveable bar, 18 inches from its extreme end K. The other end is fixed by a burr to the centre of the cog on the top of the upright, K.

M, M, two wire hooks, 7¾ inches asunder, at equal distances from the ends of the moveable bar to which they are attached. The hooks are 4¾ inches long.

N, the reel: arms 2 feet 5 inches long; 1½ inches wide; ⅞ths of an inch thick; outer rim 20¾ inches long; 2 inches deep; ⅞ths thick; one of the arms is jointed, to enable the workman to take off the silk when reeled. There ought to be an extra reel, to put in the place of the one taken off, to prevent the work stopping.

O, upright support for the axle of the reel, to which the cogs of the reel, and of the shaft E, are fixed.

P, an iron plate, 12 inches long, projecting 3½ inches from the bar, with 4 holes, through which the threads of the silk pass.

Q, the copper to contain hot water, in which the cocoons are placed, when reeling off.

R, the furnace to contain charcoal, to keep the water of the proper and uniform heat.

The copper bason is 1½ feet long, 1 foot broad, and 4½ inches deep.

Note.—B. F. Pomeroy, turner, corner of Dock and Walnut streets, Philadelphia, will make Reels, at $10 per piece, upon the plan of the one given above.

Address, by J. J. Viele, Esq.

Delivered before the N. Y. State Agricultural Society, February 6, 1839.

Gentlemen—Among the many objects, for the attainment of which associations have been formed, there is none more laudable or philanthropic in its design—none that promises greater utility in its results, than that which has for its purpose the improvement of our agriculture. Whether we view it in its effect upon the welfare and prosperity of the great mass, composing the nation, or whether we have reference only to its effect upon individual happiness, we inevitably arrive at the same conclusions. To ameliorate the condition of mankind—to multiply the blessings of Providence—to increase the productions of our country—to beautify the face of nature—to develop new sources of wealth—to diffuse knowledge, and promote the great cause of universal education—in short, to augment the nation's wealth, and promote the interest and happiness of individuals, is the great object of our association.

In the early ages of the world, it is supposed that mankind lived mostly by fishing and hunting, upon herbage and fruit, the spontaneous productions of the earth. The first step in improvement, was to the pastoral life, or the rearing and keeping of flocks and herds. As mankind increased in numbers, they began gradually to cultivate the earth, and in a measure, to obey the injunction of High Heaven, requiring them "to eat their bread in the sweat of their brows."—This employment however, was not considered the most honorable, and was mostly performed by slaves and females, while the males devoted themselves to the pursuits of war, and the chase. With the advance of civilization, agriculture became more respected, and began to be considered of more importance; but it has always been viewed by many, as a servile and menial employment, and those who pursued it, have been subject to oppressive exactions, to mantain an indolent and corrupt clergy, to defray the expenses of war, and support the administration of the affairs of State.—Land became the property of the successful chiefs, and was considered among the legitimate "spoils of victory." This was parcelled out in large tracts, among the favorites of the conqueror; and in their turn subdivided among their servile followers, on condition, and with the most solemn asseverations, "that they would, from that day forth, become their man, faithful of life and limb, and terrene honor." Here is the origin of the feudal system, under which Europe has groaned for centuries, and a landed aristocracy has been built up, and engrafted upon their governments, which the advance of civilization and free principles, has as yet in vain endeavored to shake off. Grants of large tracts by the crown, to particular favorites, entailed upon their posterity in perpetuity, and by them leased to a degraded and oppressed peasantry, borne down by tithes and oppressive taxation, are among the causes, if not the principal, why agriculture has slumbered in ignorance for ages and centuries, while the other useful arts and sciences, have advanced with a rapidity only equalled by the march of time itself.

But thanks be to the spirits of our forefathers, that we can congratulate ourselves that our lot has been cast in a land of free and equal privileges, and that we have "a goodly heritage." By the constitution and laws of our country, estates entail, and in perpetuity, have been abolished, & there is no intermediate being requiring homage and fealty, between man and his God. Yet, as our population and laws were originally derived from countries where unequal laws prevailed, and where, through their influence, great and wide distinctions had grown up in society, based not upon merit, but upon government favor and patronage—the accident of birth, or the influence of other adventitious circumstances, we could not at one blow, entirely throw them off, and rid ourselves of their baneful influence. The established principle, however, is working admirably, and it needs not the eye of prophecy to foresee that the time is not far distant, when our farmers, hitherto despised by the "*ruffle-shirt*" or "*blue-stocking*" gentry, shall have arisen from the low, degraded, and ignorant state of the oppressed peasants and serfs of the old world, to the first station in the ranks of a highly civilized and enlightened nation. This desirabe result is not to be produced by the flattering appeals of noisy demagogues, and candidates for popular favor, but by the action and combined efforts of the agriculturists themselves, seconded and aided by the co-operation of an enlightened and liberal government.

The United States of America, extending from the twenty-fifth to the fiftieth degree of north latitude, embraces a greater variety of soil and climate, than any other nation; and is capable of producing in perfection, almost every article of necessity or luxury, now afforded by any part of the civilized globe. Yet, notwithstanding these advantages of climate, soil, and government, our agriculture has been suffered to languish and decline, to an extent that almost makes us tributary to foreign powers, for the humblest necessaries of life.

> "Can such things be,
> And overcome us, like a summer's cloud,
> Without our special wonder?"

The truth is, that even in our comparatively free country; while every other interest has been fostered and encouraged by bounties, appropriations and protective duties, the humble, but all important business of agriculture has been left to take care of itself. While the other avocations have been aided and forced by artificial stimulants, agriculture has been overlooked and neglected. While the light of science has been reflected upon all the other pursuits and avocations of man, agriculture has been left to grope in darkness, unaided, unnoticed, and without any particular inducement to stimulate her sons to action. The old impressions still lingering upon the minds of men, that she was of humble and menial origin, and that the only road to honor, distinction, or even any great degree of respectability, was through the learned professions, or the pursuits of commerce. The effect produced by this state of things is, that the consumers of our country are increasing in a ratio vastly disproportioned to the producers. The professions are overstocked, mercantile business is overdone, and speculation becomes the great business of the community, instead of the ordinary pursuits of industry.

Hence it is of the greatest importance not only to the agriculturist and manufacturer, but to the real and lasting wealth and prosperity of all classes of our citizens, that by a liberal and enlightened policy, our government should adopt measures for educating those who desire to till the soil, in the arts and sciences connected therewith; thereby placing them on a level with those who are educated in other pursuits in life, and qualifying them to understand, adopt and bring forth, all valuable improvements in their various departments, and by a proper distribution of rewards and bounties to those who shall greatly excel, encourage and stimulate the industry of the producing classes, by means of which the productions of our country would be vastly increased, new sources of national wealth be opened, and our country rendered in truth and in fact, wholly independent of foreign powers. Thus we should be enabled to sell more, and buy less. The same rules govern the economy of nations, as individuals. If an individual's expenditures exceed his income, he draws upon his principal, and is made poorer in proportion to the amount of the excess. Just so with a nation, which is nothing but a vast association of individuals. If she buys more from foreign powers than she sells, she is impoverished to the full extent of that excess.

That our agriculture is not in a very prosperous condition, is evident from the fact, that although we possess a salubrious climate, and a soil scarcely equalled in fertility, we have for a few years past been dependant upon foreign nations for the necessaries of life. Millions of dollars have been expended annually, for the last few years, for those articles of domestic consumption which our own agriculture should have supplied. Wheat, rye, Indian corn, oats, barley, butter, cheese, potatoes and hay, and a vast many other articles, have been imported to supply the demands of our consumers. There is no question in the minds of many who have investigated this subject, that our own agriculture is susceptible of such an improvement as would not only obviate the necessity of importations, but produce a vast surplus for exportation. By introducing an improved system of culture, greater economy in the use of manures, double, yea, quadruple that is now obtained, might be produced; the fertility and value of the soil enhanced; old, worn out lands might be renovated; and the taxable property and wealth of the nation increased in a corresponding ratio.

In addition to the improvement of our old routine of husbandry, there remain sources of wealth to which American industry has scarcely as yet been directed. I allude particularly to the introduction and cultivation of the mulberry, and the sugar beet. That these are both objects of great national importance, will not, I think, be controverted. When we take into consideration, that the average quantity of silk imported into this country for the last seven years, amounts to the enormous sum of fourteen millions annually, it would seem that wisdom would at once suggest the policy of encouraging, by legislative bounties, the growth and manufacture of an article that enters so largely into our consumption. The manufacture of silk, it is said was introduced into Greece as early as the sixth century. It furnishes one of the staples of China, from whence a sufficient quantity of the eggs of the silk worm to commence business, were clandestinely conveyed in the hollow of a cane, by two missionaries; from whence it has spread to almost every part of Europe that is adapted to its culture. It has been found by experiment that the mulberry flourishes in almost every State in the Union, and in some of them, considerable advances have been made in the manufacture of silk. The growing of the mulberry seems well adapted to our worn out soils, as it requires not the richest land to enable it to flourish best. From the little experience that has been had in this branch of industry in this country, there is little doubt but that it might be made a most lucrative branch of agriculture.

Of scarcely less consequence than the production of silk, is the cultivation of the beet, and the manufacture of sugar. The annual imports of sugar for the last seven years, average about six millions of dollars. This vast amount might also be saved to the nation by the encouragement of this branch of husbandry. The manufacture of sugar from the beet, is of very recent origin in the world. It was first introduced into France in 1811, under the continental system of Buonaparte. It was discovered by that sagacious man, to be an object of great national concern, consequently, it was patronized and encouraged by the imperial government, until its production has swelled to the enormous amount of about one hundred millions of pounds annually, which is about half the quantity consumed by the kingdom. It has been ascertained by experiments in this country, that sugar of equal quality can be made from the beet, with that produced from the cane, and at such an expense, that it might be afforded much cheaper in the markets. Our soil is well adapted to the beet. The product per acre is variously estimated at from twenty to thirty tons, depending of course much upon the state of the soil and the knowledge with which it is cultivated. This will probably yield upon the average about six per cent of sugar, making from 2,400 lbs. to 3,600 lbs. of sugar from an acre. To this may be added the molasses and cakes, also the tops, all of which is said to be highly valuable for the feeding of stock.

If there are so many advantages to be derived from the cultivation and manufacture of these two important articles of consumption, of necessity and luxury, if our soil and climate are adapted to them, if they promise such an abundant harvest of public gain and individual profit; why it may be inquired, may we not become a great silk and sugar manufacturing people? Why may not the twenty millions of dollars that is annually sent out of the country for these commodities be saved to the nation? I answer, that it may; and it only requires that public attention should be called to the subject, correct information with regard to it be diffused, and that some legislative encouragement should be given for a short time, that the difficulties and obstacles always attending the introduction of any new enterprise, may be surmounted.

Hemp and flax are also objects of great commercial importance and domestic utility. They are supposed to be natives of the north of Africa, from the rich alluvial bottoms of the Nile. They are now cultivated almost exclusively in the provinces of Europe, situated in latitudes corresponding with our northern and eastern states. They constitute the staples of Russia and Ireland, and enter extensively into their domestic industry. No soil is better adapted to the growing of flax, than almost any of the grain lands of our country. Our rich alluvial bottoms and western prairies, would doubtless yield great returns, if appropriated to the culture of hemp. But so far are we from producing enough of these commodities for our own use and consumption, that we annually import about six hundred thousand dollars in value of sail-cloth, and about the same amount of the manufactures of flax. Almost all the fine linen that is worn in our country, is imported, and the few linen factories that we have among us, are under the necessity of sending abroad for flax and hemp, to fill out their contracts, to furnish canvass for the United States navy. It is a fact humiliating to our national pride and patriotism, that our country in the fifty-third year of her *independence*, is as yet, *dependent*, upon the empire of Russia, Ireland and the nations on the Baltic, for the canvass which floats our vessels; and upon Europe, the East Indies or China, for the fabric from which to construct the American Flag, that proud emblem of our national character and honor.

There are other important subjects requiring more particular attention from our agricultural community, but it cannot be expected, that in the short compass of an address, I shall be enabled to enumerate them all; nor can I enter into detail as to the "modus operandi" of the culture and manufacture of those, to which I have briefly alluded. At the last annual meeting of the society, committees were appointed having many of these subjects under special charge, and reports will doubtless be made replete with interest and useful instruction.

That these sources of national and individual wealth, if properly fostered and encouraged, would in a few years grow to be of vast consequence, and that upwards of twenty millions might be saved annually, in addition to their being articles of export, I have no doubt. Ignorance may reject them as innovations unworthy of a passing notice, and incredulity may smile at these fond anticipations, but he, who will take the trouble to investigate the subject, in connection with the history of agriculture in the world, and more particularly in our own country, must inevitably arrive at the same conclusions. Cotton and wool, raw and in the manufactured state, are now the great staples of our country. The history of both will show that the time is not very long since they were introduced; and that the obstacles and difficulties that they first encountered, were not less than those that now present themselves to the successful production of silk, sugar, flax or hemp. The cultivation of cotton, the great staple of the south, was first commenced in South Carolina about the year 1783. Its progress was slow, being attended with much inconvenience from the want of experience in its cultivation, and the difficulty of separating the fibre from the seed. In the year 1793, an invention was wrought out, by a young man from Mass. by the name of Eli Whitney, that completely obviated the difficulty of cleansing it. Since which time it has increased with a rapidity, and to an amount, most truly astonishing. From one million of pounds in 1789, it has increased to near five hundred millions in 1838. The quantity exported in 1792, amounted, to one hundred and fifty thousand pounds. In 1836 the exports are swelled to the enormous quantity of four hundred and forty-four millions of pounds, amounting in value to about sixty-three millions of dollars. The increase and growth of its manufacture, has also been very rapid. In 1790, there was but one small establishment of the kind in the United States, which was located in the state of Rhode Island, and contained about seventy spindles. In 1835, there was running about one million, three hundred thousand spindles. It appears from the reports of the secretary of the treasury, that above one-half of our domestic exports are derived from the culture of cotton, and that nine-tenths of our entire exports arise from agriculture.

The growth and manufacture of fine wool, is of still more recent origin, and was in its commencement, attended with great difficulties and discouragements. In 1802, the first pairs of merinos were imported into this country from France, by the public spirited and patriotic late Chancellor Livingston. It was a long time before they were received with favor, and but few years have passed since they were ridiculed and denounced, as unworthy a breathing in our free air. Yet, notwithstanding the obstacles and prejudices in the way of their introduction, they received the favorable consideration and patronage of many of the states, and have multiplied and almost replenished the land. From the best data that we have, it is calculated that the number of sheep now in the state of New-York, is about five millions; and in the United States, about twenty millons. About one-fifth of them, it is thought, are of the native, or coarse-woolled race; and the remaining four-fifths of high-grade, or full-bred Saxony and merino. Our woollen manufactures have increased in a corresponding ratio, by means of which, many millions are annually saved the nation. Wool has now become the great staple of Eastern New-York, and New-England, and a source of great individual and national wealth.

Thus we find that the cultivation of cotton at the south, and the growing of wool at the north, are comparatively of recent origin; that they were introduced and commenced under great embarrassments, and yet have grown to be the prominent and controlling interest of the country. Ought we not to inquire, whether there may not remain sources of great wealth, as yet unopened and undeveloped? And have we not reason for encouragement and perseverance, when we reflect upon the many obstacles that have been surmounted, and the many storms that have been weathered, in the history of wool and cotton? That silk, and sugar, and flax, and hemp, should be regarded as of equal importance, in a national point of view, and that they promise ultimately under proper patronage and encouragement, to become as lucrative branches of industry, I cannot entertain a reasonable doubt.

The wisdom of the policy of making judicious appropriations from the public treasury to improve our agriculture, and to encourage those productions to which our soil and climate are adapted, seems generally to be conceded, and the principle has again and again been acted upon, with reference to other interests of minor importance; but the primary business of agriculture, which belongs to all, and in which all are concerned, is made secondary in our legislation. Special legislation, private and local interests, almost always crowd themselves in advance of matters of general concern. Another reason, perhaps, why legislative action has not been had in this state, is the want of intelligence, comprehensive views, and concert of action, on the part of farmers themselves. So long as they will be blind to their own interests—so long as they will allow themselves to be the mere drudges and slaves, "the hewers of wood and the drawers of water" to the learned professions, and the other avocations of life—so long as they will consent to be the tools of power, and the mere automatons of designing politicians, just so long will their interests be disregarded, and their condition be comparatively degraded; just so long will they occupy a secondary position in the scale of respectability and honor.

Many of the states of the Union, to say nothing of foreign countries, have set a noble and praiseworthy example in patronizing and encouraging this most useful of all the arts. Almost all the New-England states are offering bounties upon wheat, silk and sugar, produced within their borders. A number of the middle, southern and western states, are also turning their attention to these subjects. Foreign nations have, for a long time seen the necessity of doing something to make more broad, and stable, and sure, this foundation of a nation's greatness and glory. The result of this policy is, that the old world, instead of being our market place, produces a surplus with which it supplies the deficiency of our miserably neglected soil. It is to be hoped that New-York, proudly styled the Empire State, will follow, if not lead, in this noble enterprise. With an extent of territory greater than many of the kingdoms of the world; with a population amounting to about one-sixth of the Union; with a salubrious climate, whose fertility is unrivalled, why will she lag behind her sister states and the world, in this march of improvement? The subject of internal improvement seems to engross, at this time, much of the public attention. But our authorities should recollect, that however important and useful they may be, it is not *alone* rail-roads or canals, or mushroom cities and villages, that enrich a nation. Although that species of improvement is, to a certain extent, desirable, it should not be forgotten, that the internal improvements which contribute most to enrich a country, are those which improve and fertilize the soil, adorn the face of nature, increase the productions and enhance the value of the land. It is the successful cultivation of the soil *alone*, that furnishes the means for the support of villages, cities, railroads and canals. If that is left to languish and decline, the former will fall into premature decay, and the latter will truly become "solitudes and desert wastes of waters."

(Concluded in our next.)

Young Men's Department.

Hints to Young Farmers.

NO. XIII.—"DESPISE NOT SMALL THINGS."

The small trees that were set out by your fathers, have grown into a fruit-bearing orchard, and yield subsistence to the family and the farm stock. The once puny saplings which in childhood you assisted to plant about the house, give shelter and picturesque beauty to the old homestead. The grape cutting has become a wide spreading vine, and yields an annual tribute of luscious fruit. The acorn has grown to a towering oak. How many of the comforts and pleasures which you enjoy, do you owe to the happy circumstance that your parents *did not despise small things?*

Our passions and habits, like the oak and the apple-tree, have their small beginnings. We may train them to our will, and render them subservient to the noblest purposes of life. Thus the seeds of useful knowledge, planted in early life, will spring up, and give an abundant increase in manhood. Thus, too, habits of industry and frugality, established in youth, although then often considered *small things*, are the germs of wealth and happiness in riper years. Moral soundness and purity will lead to honor and respect; while the habit of scrupulously respecting the rights, and promoting the welfare of our neighbors, is the surest means of obtaining what we all stand in need of, the kind offices and good will of others. If these *small things* are not regarded while the twig may yet be bent, you cannot rationally expect to enjoy the pleasures and profits which they yield in maturer life.

The vegetables must be planted while they are yet *small things*, and they must be nurtured and protected, or they will fail to yield the promised food and shelter. The good habits, too, must be established in the germ of life, and the passions disciplined, if you would realize the parallel of usefulness and beauty. The plants may become the property of others, and you lose the promised reward of fruit. But your good habits and sound principles are exclusively your own. You can enjoy the rewards they bring, while you live, and can indulge the hope that your children will be benefitted by the influence of your example.

Plant trees and vines, that they may yield you the comforts of life: cultivate the better passions, and establish the good habits, in yourself and children, that you may all truly *enjoy* those comforts.

NO. XIV.—TIME IS CAPITAL.

Every young man has this capital at command, when he reaches the age of manhood; and in this respect all are equal. We may state it at an average, at one thousand dollars; because every prudent laborer, if he is blessed with health and a tolerable knowledge of any useful business, may save from his annual earnings seventy dollars. This seventy dollars, accumulated annually from one's earnings, and prudently husbanded, will, at the end of ten years, form an aggregate of more than one thousand dollars; and if continued ten years longer, will have accumulated to nearly three thousand dollars. Every dollar saved, and duly vested in the outset of life, multiplies progressively as time advances.

How differently do young men employ this capital! Those who best appreciate its value, and who employ it to the best advantage, are such as depend upon it solely as the *foundation* of their fortunes—who do not lean upon a paternal inheritance. The most wealthy and distinguished men of our country were of this class; whose time constituted the only capital they had to begin the world with, and who, with this beginning, which every young man has equally at command, have accumulated vast fortunes. With them time has truly been money.

On the other hand, when we have seen young men, either because they did not appreciate its value, or because they relied too much upon hereditary rank and fortune, throw away this capital—this time of youth—or waste it in frivolity and fashion, we have generally seen them sinking in the scale of society, both in regard to wealth and usefulness; and have too often seen them reduced to want or to crime.

If the young man will look about, and inquire into the early habits of the generation before him, he will find abundant reason to concur with us in opinion, that *time is capital*—is money—which, if discreetly employed in the outset of life, will lead to fortune and happiness; but which if wasted, or unemployed, will give neither increase nor character to its possessor.

We have assumed as the basis of our comparison, the time of a common laboring man, who exerts merely his bodily and mechanical powers. We have made no reference to the powers of the intellect. Where these are brought out, by reading, observation and reflection, and made auxiliary to labor, they very materially enhance the value of the capital of which we are speaking. They add to its value two, three and four fold. A common laborer's time may be stated at $110 a year; while there are others, whose education qualifies them for higher duties, whose services will command twice, thrice, nay ten times as great a salary; so that every young man who expects to start in life with the bare capital of his time, has it in his power very much to increase the value of this capital, by the early improvement of his mind. Thousands and tens of thousands are constantly making experiments and improvements in agriculture, a knowledge of which would double or treble the profits of his labor. These experiments and these improvements are registered in our agricultural periodicals; and he may obtain an early knowledge of them for a trifle, and without infringing upon his labors, and may apply them to the increase, and consequently to the income of that capital. There is no art, no calling, but demands industry and perseverance, to attain to excellence in; and there is probably no business to which this remark is more applicable, than to agriculture. It embraces the whole of animated nature—the animal and vegetable kingdoms—and the crust of the globe which he works. Were the farmer to live the age of the patriarchs, he might continue to learn something useful in his business to the last day of his life.

How to Ruin a Son.

1. Let him have his own way.
2. Allow him free use of money.
3. Suffer him to rove where he pleases on the Sabbath.
4. Give him full access to his wicked companions.
5. Call him to no account for his evenings.
6. Furnish him with no stated employment.

Pursue either of these ways and you will experience a most marvellous deliverance, or will have to mourn over a debased and ruined child! Thousands have realized the sad result, and have gone mourning to the grave.—*Philadelphia Observer.*

*Moneys received up to 20th of April, in sums of five dollars and over. The total receipts are included from post-offices marked with an asterisk.**

PACKARD, VAN BENTHUYSEN & Co.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. JUNE, 1839. No. 4.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, D. LANDREITH, and M. S. POWELL, seedsmen, Philadelphia; ISRAEL POST, bookseller, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; HOVEY & Co. Merchants' Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

☞ To our Patrons. ☜

In order that our next volume may begin with the commencement of the year 1840, the time when most of the periodicals commence their volumes, we propose to finish volume VI. in the current year, by publishing a number on the 15th of August, and another on the 15th of October, in addition to the usual monthly publications —if serious objections are not raised to this arrangement by our patrons.

☞ Failures by Mail.

☞ We are in the receipt of notices, almost daily, of moneys being sent to us by mail, which have never come to our hands. The amount thus lost is too great to suffer without repining; nevertheless, as we have assumed the risk of this mode of transmitting moneys to us, we must suffer the loss, *where satisfactory proof is rendered, that the moneys so presumed to be lost, were actually mailed*—a condition which we are obliged to insist on.

☞ We would suggest to publishers and others, that that notify the General Post-office of all failures in the receipt of moneys by mail, with dates, &c. in order to facilitate the detection of the rogues who violate their duty.

Horticultural Society of the Valley of the Hudson.

☞ In another column will be found a notice for a semi-annual exhibition of this society, to be made at the City-Hall in Albany, on the 25th of June instant.

The object of this association is stated in the notice. Should the institution be sustained, as we think it ought to be, by the liberal and enlightened inhabitants of our valley, it cannot fail of becoming highly serviceable in introducing among us all the more valuable varieties of fruits and ornamental plants, in diffusing a taste for rural embellishment, and in multiplying our domestic and social enjoyments. The descriptive catalogue of Pears, which we this day publish, will serve as an indication of the public service that may be rendered in the fruit department, by the labors of the association. We cultivate much fruit, but we cultivate but comparatively little which may be considered of the first quality.—Our garden productions are as susceptible of great improvement in their qualities as are our fruits. We unite our earnest invitation to that of the secretary, for contributions to the exhibition, and for the countenance and support of the friends of horticultural improvement. The exhibition will probably be kept open two days.

Aid to Agriculture.

We have refrained from noticing any of the proceedings of the legislature in regard to the encouragement of agriculture, from a conviction forced upon us by past experience, that nothing would be done to aid this great branch of industry.

Mr. C. E. Clarke, of Jefferson, chairman of the committee on agriculture in the assembly, introduced two bills into that house, one appropriating $25,000 annually for five years, to be awarded in premiums in the several counties, and to pay the *expenses* of a board of agriculture, and the salary of its secretary—and the other to encourage the growth of silk, by awarding bounties to those of our farmers who should raise it. These bills were each accompanied by a very able report, setting forth the many and manifest advantages which would result to the state from the passage of these hills into laws. Both bills passed the house of assembly, by respectable majorities, and were sent to the senate.—The silk bill was rejected in senate, and the one to improve the agriculture of this state, was virtually rejected there on the last day of the session, by an order to lay it on the table. The motion was made by Col. Young, who said "he could not in conscience suffer such a mischievous and dangerous bill as the agricultural bill to pass without fully discussing it."

We give the vote upon Col. Young's motion, in order that our readers may be enabled to censure or applaud, as they think meet, the conduct of their public servants.

Ayes.—Messrs. Beardsley, Clarke, Dickinson, Hull, Hunter, Huntington, Johnson, E. P. Livingston, Paige, Powers, Skinner, Spraker, Sterling, Van Dyck, Wager, Young—16.

Noes—Messrs. Fox, Furman, Hawkins, Jones, Lee, H. A. Livingston, Maynard, Moseley, Nicholas, Peck, Tallmadge, Verplanck, Works—13.

We confess that we are not familiar with the details of either bill, and therefore feel unqualified to speak distinctly of their merits; yet we are persuaded that something ought to have been done, and might have been done, had there been a disposition to do it. And we are wholly at a loss to conjecture what could have been the "mischievous and dangerous" principles in the bill, which so alarmed the sage senator and his compeers. We cannot but regret, that in a matter which most deeply concerns the interest of every class of community, party feeling should seem to have smothered the nobler impulse of public duty. Several of the gentlemen who voted against this bill, have professed to be friendly to its objects, and one of them reported, not long since, a bill of very similar import. If the details of the one now rejected were defective, they might have had it modified, or at least have made the attempt to do it.

It requires no great discrimination to perceive, that party spirit—the thirst for power and office, in the latitude in which it is now indulged—holds a paramount sway in our legislative halls, as well as in political meetings;—that it is the bane of whatever is generous, and disinterested, and patriotic, and great, and good;—that it infuses its poison not only into our legislative halls, but into the cup of our social enjoyments; and that its tendency is to impair the public morals, and loosen the bonds which unite us as a people. The question now, is not, what will best subserve the public good? but—what will best promote the interests of party?—and in the scramble for power, whatever measure is not likely to increase the political capital of a party, will pretty surely be opposed on party grounds—and whatever measure is advocated, or whatever individual is supported, by one political party, is as sure to be opposed and traduced by the other.*

Banks have, for a long time, been the locomotives of power, till the country has become far too full of them, and until they can no longer be made to exert a favorable political influence. Millions have been expended in canals, to subserve political ends, which are not likely to pay the interest on their cost for a long time to come, if ever. The eye of the politician is now directed to rail-roads, as the great avenues to public favor; and bills involving the responsibility of the state for many millions, have been in progress of passing into laws, for the construction of rail-roads, in the stock of some of which a prudent man would hardly make a permanent investment, at one-fifth of the par value of the stock. We are not opposed to canals or rail-roads, to a reasonable extent, where they promise manifest public usefulness, or any thing like ultimate remuneration for the outlay; but now-a-days they come in batches, as banks came formerly—the bad with the good—and by modern arts of legerdemain, they are so intimately joined and interwoven, that it is difficult to separate them; so that there is no alternative but to reject all, or adopt all.

We have been drawn from our purpose, which was merely to recommend to the friends of agricultural improvement, a steady perseverance in their praiseworthy efforts for the substantial improvement of their country —by the diffusion of useful knowledge, and in encouraging and honoring rural labor. In this way, the next generation which comes upon the stage, may be made to appreciate the value of our agriculture, and the policy and the duty of encouraging its improvement.

In what condition should Manure be applied?

While one set of men, embracing both practical and theoretical, contend that manures should be buried by the plough, at the bottom of the furrow, another set as pertinaciously insist that they should be covered only superficially with the harrow—the first contending that the fertilizing matters which they afford, *rise to the surface*, and the other, that they *sink* below the cultivated stratum. We copy to-day two articles from the Yankee Farmer, maintaining the opposite doctrines. A material distinction seems to have escaped the notice of both the writers, and that is—the *condition of the manure to be applied*—whether fermented or unfermented.

There is no fact better established, we believe, by chemical experiment, than that stable manure loses one-half of its fertilizing properties, by fermenting in mass, in a situation exposed to the influence of the sun and winds. A partial decomposition takes place, and the gaseous and most soluble parts are either scattered by the winds, or carried off by the rains. It is an equally well established fact, that if the fermentation takes place *in* the soil, these gaseous and soluble portions of the manure are retained there, are imbibed by the spongioles, or mouths, of the young crop, and that they contribute essentially to its growth and product. Now if long manure is spread upon the surface, these gaseous matters are lost, for they are specifically lighter than atmospheric air, as any one may see by observing the steam which rises from a fermenting dung heap. If long dung is only superficially covered with a harrow, it will but partially decompose, for lack of moisture, an indispensable agent in the process of fermentation. If, on the other hand, the manure is buried with the plough, it not only benefits by its gaseous matters, but it generates heat and benefits mechanically, by rendering the soil more open, and permeable to heat, air and moisture; it facilitates the decomposition of vegetable food, accelerates growth, and increases the product. And fermentation having exhausted its powers during the first season, in the culture of the hoed crop—for to such alone do we advise that long manure should be applied,—the plough turns to the surface, the coming spring, the carbonaceous parts of the manure which remain, where they operate most beneficially upon the coming crop.

The only plausible objection to burying long manure with the plough, in preference to mixing it with the surface by the harrow, is that adduced by Prof. Jackson, that the rains carry down its fertilizing matters into the subsoil—into wells and springs, beyond the reach of the roots of plants. With the highest deference for the Professor's opinion, we must be permitted to doubt the correctness of his conclusions in this matter. If the soluble salts were carried into the subsoil, as he supposes, this subsoil would be rendered fertile by them when it is turned to the surface, a proof that seldom occurs, until the subsoil is rendered fertile by long exposure to atmospheric influence. Nor do we admit that springs and wells are prejudiced by them, unless the water which holds them in solution, finds a direct passage into such springs or wells from the surface of the earth. We do know that impure water is purified by being filtered through charcoal and sand, and that pure springs burst forth from impure soils.

When we speak of fermented manures, or of such as are to undergo but a moderate fermentation, as rotten dung, bone dust, horn shavings, poudrette, &c. a different rule applies, and a different practice should be adopted. Those give off no gaseous fertilizing matters to the winds. Their only tendency is to sink in the soil.—Hence if they are blended by the harrow with the surface, they are calculated to act more efficiently than if buried deep by the plough.

Catalogue of Pears.

The varieties of the pear, until within a few years, have been few, and the quality, with some exceptions, indifferent or inferior. But through the active exertions of Dr. Van Mons, of the Netherlands, Mr. Knight, and other distinguished pomologists and horticulturists, the varieties have been greatly increased; and among the number now cultivated we have some of excellent quality, that are in eating during eleven months in the year.

The pear is used for the table, for stewing and baking in the kitchen, and for Perry. As most of the varieties now found in our nursery catalogues are new, and their quality, time of ripening, and the uses to which they are particularly adapted, but imperfectly known, even to nurserymen, great difficulty is experienced in making a judicious selection, that shall give a succession of fruit. We have frequently experienced this difficulty ourselves. To assist both the purchaser and the seller, and to disseminate a knowledge of the best varieties, we publish the catalogue below.

The London Horticultural Society published, in 1831, a list of 677 varieties of the pear, which were then growing in their garden. Of these, 278 kinds only had then fruited. These are described in a tabular form, and divided into three classes as to size and form—their time of ripening, their use, their color, and form and texture noted, and remarks subjoined as to the character of the tree, &c. From this catalogue our list is principally taken. And it is proper to remark, that the kinds that have proved to be the best, on comparison, in the Horticultural Garden near London, have not in all cases proved to be of a like character in America—some of No. 1 in quality being here No. 2, and some of No. 2, being No. 1 with us. Our list embraces all of No. 1 in the catalogue of the Horticultural Society, which had fruited there in 1831, and such of No. 2 as are known to be in our nurseries, but none of No. 3. There are some American varieties not named here, because we cannot speak with certainty of their quality, time of ripening, &c.

---

* "Our institutions do not cultivate us," says the Rev. Dr. Channing, "as they might and should; and the chief cause of the failure is plain. It is the strength of party spirit; and so blighting is its influence, so fatal to self-culture, that I feel myself bound to warn every man against it, who has any desire of improvement. I do not tell you it will destroy your country. It wages a worse war against yourselves. Truth, justice, candor, fair dealing, sound judgment, self-control, and kind affections, are its natural and perpetual prey."—*On Self-Culture.*

We have endeavored to procure all the most esteemed varieties of the pear; and have succeeded in introducing into the Albany Nursery, from the London Horticultural Society's Garden, and from the best nurserymen about London, all the esteemed varieties, embracing several not included in this list, of high repute, which have come into bearing since the catalogue was published. Such as we have for sale, are marked by an asterisk. (*)

To aid the purchaser, who may be desirous of obtaining a succession of choice pears, we have classed them according to their time of ripening, into seven classes, those of the largest size, and of the first quality, being indicated by figure 1, and those particularly adapted for stewing and baking forming the seventh class. The synonymes are very numerous. We give, in *italics*, those only which are best known. By selecting one or more from each class, the purchaser will be sure of having a succession of this fine fruit ten or eleven months in the twelve.

NAMES AND SYNONYMES.	*Size.*	*Quality.*
CLASS I.—SUMMER PEARS, *Ripening in July and August.*		
1. *Bergamot, early,	2	2
2. *Bergamot, orange,	3	2
3. *Bon Chretien, Williams's, *Bartlet*,	1	2

Multiplication of the Multicaulis.

From the partial observation we have been able to make at the south, we are induced to believe, that the stock of the Morus Multicaulis, in the Atlantic states, will be increased to the extent of fifty millions of plants in 1839. We were informed at Burlington, N. J. that a million of young plants would be grown this season, within a mile and a half of that city. We were informed by two growers in Philadelphia, that they would raise, each of them, 200,000 plants. Indeed the propagation of this plant seems to engross the attention of great numbers of almost every class of the inhabitants south of lat. 42°. The importations from France, from the West-Indies, and from Florida, have been immense; and so late as the 10th May, they commanded from forty to seventy cents, by the hundred, at auction, in the New-York market. At the present rate of increase, one thing seems to be certain, that the public attention must soon be directed less to the *buds*, and more to the *leaves*—less to speculation in trees, and more to their use in the manufacture of silk—or that we shall ere long fail to realize all our golden dreams. The art of propagating has been so improved, as to render the ratio of increase astonishing. A single bud, or a piece of root, is placed in a green house, or in a hot-bed, or under glass, in January. It soon sends forth a shoot, and as soon as this is three or four inches long, it is cut off near the surface, the plant springs up afresh, the cutting is inserted in a pot of earth, where it grows. In a short time, under a warm temperature, which may be easily maintained, the parent and the cutting will each furnish the germ of a new plant. This process of multiplying may be kept up till June or July, and thus a single bud will become the parent of many plants, in a few weeks, and these plants will yield thirty or forty buds in autumn, attain a height of two to five feet, and be of marketable size. If each bud in this way makes three plants, and each plant grows forty buds, the increase will be one hundred and twenty fold. Thus, if prices keep up, the purchaser and propagator of one thousand buds, at three cents each, may clear by this small operation, upon the basis of the above calculation, the pretty sum of $3,300—a profit that has been more than realized in some cases.

We give the preceding estimate of profits, not to induce our readers *now* to embark largely in the business—for prices must unavoidably come down—but to show the exciting causes of the prevailing multicaulis fever, and the source of the enormous profits which the business has hitherto afforded.

The result of the multicaulis speculation will probably be—that many will make fortunes—that the tree will be extensively multiplied, and widely disseminated—and although some will be "*saddle-backed*," the country at large will be manifestly benefitted, and the silk business established as a productive branch of national industry, on a basis which nothing human is likely to overthrow.

In making these remarks, we do not intend to acknowledge any superiority in the multicaulis, over other species and varieties of the mulberry, for silk, and especially for northern culture. We have had but little personal experience in the silk business; and although our notions may be erroneous, we do not think the multicaulis is the best mulberry for silk, in our latitude, even though it were as hardy as other varieties, which it is not; for it has been entirely killed with us, while other varieties have stood unscathed by the winter's cold. The multicaulis seems about as tender as the sweet water or chasselas grape, which requires a protection of earth to preserve it during winter. Those, therefore, who mean to cultivate it, among us, for the leaves, are again cautioned to take up the young plants in autumn, and to cut down and cover the stumps of the larger ones. They may survive a mild winter, but they will almost assuredly be seriously injured or destroyed in a severe one.

The Rohan Potato,

Has become, next to the multicaulis, a prominent article of speculation, among the cultivators of the soil. We verily think it a valuable acquisition to American husbandry. But when we sold off our crop in October, at $2 and $3 the bushel, we had not a suspicion that the article would reach the price at which it has since been sold. The price has risen to twenty dollars a bushel, and the retailer, who has bought at this price, has realized a handsome nett profit by the purchase.

The Rohan is capable of yielding almost as rapid an increase as the multicaulis, and has certainly other high qualities to recommend it. And we have this further consideration to console us, that without the high prices which both the Multicaulis and the Rohan have borne, they would never have attracted so great a share of public attention, or have been so widely disseminated. At a low price, few would have regarded them as worthy of notice; as a gift they would have been thanklessly received, and little cared for; but as expensive articles, and of real intrinsic value, they are eagerly sought for, and carefully cultivated.—The spirit of agricultural improvement, which is abroad, will be annually adding to our valuable products; and it will happen as it has already happened, that those who are most forward to profit by the information and improvements of the day, will reap the best reward. And no man can expect to profit by this information and these improvements, except he is a subscriber, and an attentive reader, of some agricultural periodical, which registers and promulgates these improvements. Upon a limited estimate, there are ten millions of men, in Europe and America, who are devoting their time to enlighten the labors of the farmer, by which we mean, to render those labors more profitable. Whatever is most interesting and important, is communicated to the local agricultural journals, and by the interchange of these which takes place, the several editors are enabled to transfer to their columns whatever is likely to benefit their particular readers. Thus we are advised, immediately upon their introduction either in Europe or America, of every new species of plant, breed of farm stock, implement of husbandry, or mode of agricultural practice, which is likely to prove serviceable to our readers; and if we have discrimination and practical knowledge enough to separate the wheat from the chaff, the former is distributed monthly or oftener to our customers; and if they are wise and spirited, they appropriate it to their personal use, and get their twenty and fifty fold recompense.

Thus the readers of agricultural journals are enabled to apply to their personal use, the discoveries and improvements which are daily making in their business; while the farmer who reads nothing, who is content to be guided by instinct, or what is but little better, the light of his individual experience, derives little or no advantage from the discoveries of science, or the march of improvement, which so eminently distinguish the age, and which are daily abridging the fatigues, and increasing the profits of labor, in every department of productive industry.

The March number of the Farmers' Magazine, contains the first notice we have seen in the British agricultural periodicals of the culture of this root in England. G. Kimberly states, that in 1836, he obtained, through a friend at Paris, sixty moderately sized tubers; from which, although planted under trees, and suffering much from drought, he obtained, in 1837, 24 bushels full measure—the vines growing eight feet. These he planted last year, and obtained a most extraordinary yield. This potato is frequently exhibited in the Paris market, of ten pounds weight. They are cut in slices of about two inches thick, boiled well, and are pronounced to be very farinacious, or mealy, and of fine flavor.

The Value of Turnips.

"The introduction and cultivation of green crops," says the London Farmers' Magazine, "constitutes an era in the history of agriculture, not less important, or less valuable, than any of the splendid discoveries which have added so much to the value of other arts, and though some real, or rather supposed causes, have retarded a more extensive and easily practicable cultivation, the progress hitherto made, has doubled our agricultural produce, has afforded a better and more regular supply of food, and has added to the general comforts of every class of society. An extended cultivation of green crops, (roots and clover,) joined with our more modern discoveries, would nearly again double our agricultural produce; and the day is fast approaching, when all restrictions and fetters imposed by ignorance, prejudice and power, must snap before the march of intellect, and our common wants, and allow the cultivation of this art to proceed with other arts, and to take advantage of every known means of improvement, to supply the primary and indispensable requisites of life. Self-interest and individual gratification must ultimately give way to the general good."

Here is an opinion expressed, after a half century's experience, on a broad scale, that green crops, consisting principally of turnips and clover, have doubled the agricultural products of Great Britain; and that an extended cultivation of these crops might be made again to double her products. The turnip culture had all the insect enemies to combat, and all the prejudices to overcome, in Great Britain, which it has now to encounter among us; yet it has triumphed, and the land has been enriched, and the farmers prospered. It is not so much the immediate profit of the crop, as the tendency to improve the fertility of the farm, that gives to green crops their intrinsic merit. They afford a profitable means of increasing the fertility of the soil, which no other class of crops can furnish.

It is true, that in England, the main turnip crop is fed off by stock, or drawn and fed in an adjoining field, the economy of which practice is, however, questioned by many intelligent English farmers. Francis Blaikie, in the Farmers' Magazine, states his practice to be, to draw his Swedes in November, top them and cart them to an orchard, or other old turf, where they are *placed*, as he expresses it—that is, the bulbs are placed so close as to touch each other, tops up, and one tier deep. In severe weather, a slight covering of litter, here it might be earth, is thrown upon them. In such situations, says Mr. Blaikie, we have had them keep good till midsummer—if under a shade, the better. They strike fresh fibres into the ground; they are not liable to rot, nor will they become too dry for use. This hint deserves notice from our farmers. Although kept in pits in winter, they might be thus advantageously placed in early spring, and thus preserved for late feeding—the Swede enduring a considerable degree of frost without injury.

In a subsequent communication, Mr. Blaikie states, that he had preserved several acres of turnips in the manner above described; that they remained the whole winter without any covering, except by occasional falls of snow; that they were very little injured by the weather, while two-thirds of the remainder of the same crop, left in the fields, perished and became rotten; and that at the date of his writing, April 6, he had quantities remaining in fine condition.

Anglo-Merino Sheep.

This is the name given to a new breed of sheep in England, produced by a cross between the Merino and English long-woolled sheep, which has been brought to a state of excellence by Lord Western. Fine samples of this cross attracted admiration at the last Smithfield cattle show, and have been since the subject of frequent comment in the British agricultural periodicals. In the March number of the (London) Farmers' Magazine, we find a letter from Lord Western, accompanied by documentary proof, setting forth the high value of this new breed, as regards both carcass and fleece. The object of his lordship was to implant the Merino wool on the Leicester carcass; and although he admits that his sheep may not fat so early, or come to the size of the improved South-Down, still less to the weight of the Leicester, yet they give a handsome carcass, and carry a heavy fleece of equal to Merino wool; and are, withal, an improvement in hardiness, upon the pure Merinos. The carcasses of some of his shearling wethers weighed 150 lbs. 20 to 25 lbs. of which was gut fat; and his two shears weighed a little more. The wool of the cross-breed averaged over 5½ lbs. in a flock of 201 sheep.

Mildew on Grapes.

A. J. Downing, a good authority, states, in the Horticultural Magazine, that foreign grapes, as the Sweetwater, Chasselas, &c. may be preserved from mildew, by securing an annual succession of new plants, which is effected with very little trouble, by layering a thrifty shoot of the old vine in June, of some five to eight feet in length, which takes root, and produces fruit for one or two seasons, not subject to mildew. The layer is separated the next season, and the old plant dug up and thrown away. It is a common remark, that the foreign grape will be free from mildew one or two seasons after it comes into bearing, but that it is afterwards subject to mildew. The cause has not been satisfactorily explained. The finest vine of a foreign grape which we ever saw, grew in the garden of the late Judge Scott, of Catskill. We saw it in several successive years, when the fruit was at maturity, and it had no appearance of mildew. This exemption from mildew, the Judge ascribed to the circumstance of his having placed a large flat stone in the bottom of the hole before planting his vine—and which prevented the roots from penetrating the subsoil, the conjectural cause of the mildew.

Silk Manuals and Silk Periodicals.

There has been recently published, or republished, Silk Manuals, by Cobb, Kenrick and Whitmarsh, of Massachusetts, by Dennis of Rhode-Island, and by Roberts of Maryland. Of these we have seen Whitmarsh's, of which we have spoken, and Dennis's. Roberts has been complimented, in a substantial manner, by the legislature of Pennsylvania, who have resolved to purchase fifteen hundred copies of the author, E. R. Roberts, editor of the Farmer and Gardener, for distribution among the inhabitants of that State. Every silk grower should possess one of these manuals.

There are also now published, in the Atlantic states, the following periodicals, devoted almost wholly to the silk business, besides several, we believe, in the western states, which will also be found highly useful in the management of the mulberry and the silk-worm, viz. *Journal of the American Silk Society and Rural Economist*, published at Baltimore, Md. at $2 per annum—address G. B. Smith; the *Silk Culturist*, published at Weathersfield, Ct. by Judge Comstock; the American *Silk Grower*, published at Philadelphia, by Ward Cheeney & Brothers, the *Southern Silk Grower*, published at Baltimore, by E. Y. Reese; and another is published at Keene, N. H. the title and publisher of which are unknown to us.

Mr. Dennis's Silk Manual contains more than a hundred pages in small type. From the cursory perusal which we have given it, we are of opinion that it will serve as an excellent guide to beginners, and that it contains much valuable matter, in relation to rearing the mulberry, the management of the worms, and the manufacture of silk, which may be useful to those who may claim to be proficients in the business. We subjoin Mr. Dennis's

"TWENTY-TWO REASONS

"*Why the Farmers of the United States should raise Mulberry Trees and Silk.*

"1. Because it is a very certain crop.

"2. Because silk is as easy raised as wheat, and much less laborious.

"3. Because raw silk, or cocoons, will command cash in the market, and at a handsome profit to the producer

"4. Because a pound of silk can be raised to a much greater profit than a pound of wool.

"5. Because three pounds of silk can be produced from the same land that would produce one pound of wool.

"6. Because one pound of raw silk will sell for six dollars, and one pound of wool for fifty cents.

"7. Because the labor of raising silk is performed in six weeks, while the labor of taking care of sheep, and providing them with food, lasts all the year.

"8. Because the labor may be performed by children, or feeble persons, whose services would be worth very little for any other purpose.

"9. Because there can be considerable quantities raised, without materially diminishing the other products of the farm.

"10. Because the climate and soil are as well, if not better, adapted to the growth of the mulberry and the production of silk, than any part of Europe.

"11. Because there is no probability, and scarcely a possibility, of the business being overdone.

"12. Because mulberry trees are easier raised than almost any other tree.

"13. Because the timber of the mulberry tree is worth as much as locust, for building ships, fences, or any other purpose.

"14. Because large mulberry trees injure the crops growing under them, less than almost any other tree.

"15. Because mulberry leaves, when green, are greedily eaten by cattle, hogs, and sheep; when cured like grass to make hay, are an excellent food for cattle and sheep.

"16. Because land cultivated with mulberry trees, and the litter from the worms spread upon it, would be impoverished less than if cultivated with almost any other crop.

"17. Because it will cost no more to transport a pound of silk to market, that will sell for six dollars, than it would to transport a pound of bread stuff, that would sell for six cents.

"18. Because the small sum of five dollars, or even one, expended in purchasing mulberry seeds and cuttings, with a little care in cultivation for a few years, will enable a farmer to produce considerable quantities of silk.

"19. Because the eggs can be kept in an ice house until the middle or last of the seventh month, (July,) and then the worms can be hatched and fed after the busy season of mowing or harvest is over.

"20. Because the man, with a little land, who has a family, can increase his mulberry trees and keep his family employed at home, without the risk of sending them abroad for employment, where they would be liable to have their morals corrupted.

"21. Because it would relieve the nation from paying millions of dollars annually, to other nations for silk.

"22. Because there are twenty or twenty-five silk manufactories already established; several of which have been stopped, waiting for the importations of raw silk."

Agricultural Periodicals,

Have been multiplied among us till their number exceeds thirty in the United States, and even the family of "Cultivators" has increased to six or seven—in 1819, there was but one—and the correspondents to these journals have become so numerous, that it is impossible for any one editor to copy from others all, or but a small portion, of what he may find in them, interesting and profitable to his readers. Original communications, possessing ordinary merit, are ever entitled to precedence; and every editor feels himself under obligation to labor somewhat personally in his vocation. We have ourselves felt embarrassed for want of room to insert articles of merit which have originated in other agricultural journals; but have been obliged, from the number of our correspondents, with whom we are desirous of maintaining a good understanding, to forego this satisfaction. The truth is, that although every agricultural journal may contain *many* good things, no one of them is capable of publishing *all* the good things which are issued from the agricultural press, and which are calculated to improve the soil and the mind.

Under this situation of things, we submit to the consideration of the independent farmer, whether he will not find it to his interest, and that of his sons, to extend his patronage to more than one of these journals—whether ten dollars, the price of a daily political journal, might not be profitably expended in this way, in the subscription to half a dozen agricultural journals.

The editors of the Farmers' Cabinet, Philadelphia, appreciating these facts, and to meet the requests of their friends, have offered to become local agents for all agricultural works. We meet their offer in a spirit of liberal feeling, and tender a reciprocity of favors. Subscriptions for the Farmers' Cabinet, or any other agricultural periodical, will be received at the office of the Cultivator.

Horticultural Publications.

Robert Buist, of Philadelphia, one of our best practical gardeners, has just published *The American Flower Garden Directory*, containing ample directions for the selection of flowers, and for their management in the garden, green house, parlor, &c.—400 pages.

E. Sayres, formerly of this city, has published at Boston, *The American Fruit Garden Companion*, being a treatise on the propagation and culture of fruits in the middle and northern states—170 pages 12mo.

Although we have been presented with the latter of these works, we have not had time to give it that examination which will justify us in speaking of its merits.

The Season

Has hitherto been very auspicious, and so far the prospect of an abundant harvest is highly encouraging. Our correspondent at Emmettsburgh, Md. writes, "the wheat in this county bids fair to be considerably over an average crop." We have heard the prospects spoken of as flattering from most parts of the country, without any material drawback. The clover has suffered considerably from the want of its accustomed fleecy covering in winter. The weather in April was unusually warm, vegetation shot forth luxuriantly, and the season on the first of May was two weeks earlier than usual.

Since writing the above notice, we have made a tour as far south as Philadelphia. From personal observation, and from the information of travellers, we are fully confirmed in the opinion, that the harvest prospects of the winter grain crop are almost every where propitious.

The Tendency of Rail-Roads

Seems to be, to retard the growth of small cities, or at least to concentrate business more in the large ones, to which they greatly shorten distances. We lately took the rail-road through New-Jersey, in order to see the cities of Newark, New-Brunswick and Trenton, and the villages of Elizabethtown, Princeton, &c. but to our surprise, we did not pass through any of them, and some of them we had hardly a distant view of. Where rail-roads have been constructed, they now engross almost the entire travel; and the traveller seldom stops more than five or ten minutes, at any intermediate points, unless he has special business to detain him. In moving at the rate of one hundred miles in six hours, one has hardly an opportunity of seeing the country, much less of seeing, or doing business, in the towns and villages.

New-York Geological Report.

The Reports communicated to the Legislature at the recent session, of several of the gentlemen belonging to the geological corps, comprises about 350 pages, and contains many matters interesting to the farmer. We shall endeavor to select the most interesting of these for publication, particularly those which develop mineral and vegetable sources of fertility.

The first communication is from Messrs. Emmons and Hall, suggesting the propriety of a suitable building being prepared for the reception and arrangement of the specimens collected by the gentlemen engaged in the geological survey—a suggestion which highly merited, but which we believe did not receive, the efficient consideration of the legislature. These specimens will be of incalculable benefit in future time—they will constitute a museum of the natural productions of our state—animal, vegetable and mineral—of great interest to the naturalist, and of essential use to the farmer and mechanic. And when we consider that the number of minerals, fossils, &c. will probably exceed 4,000, the importance of the state providing a suitable place for their deposite and classification, must be apparent to all.—We pay some 120 to $150,000 for the geological survey; and the money will be well expended, if we profit, as we may, from the labors of the corps. We are afraid, however, that like the labors of agriculture, the valuable services of this corps, will be treated by our legislatures, as of minor importance, when put in competition with party politics and rail-roads. We shall be exceedingly happy to acknowledge ourselves mistaken in this opinion.

The second article in the governor's communication is the report of Dr. L. C. Beck, on the *Mineralogical and Chemical Department of the survey*. The report com prises a general view of what has been done in this department. It commences with a tabular view of the minerals which have hitherto been found in the state, which is followed by concise remarks on each. We shall confine our notice to such as are more immediately interesting to the farmer.

ANTHRACITE AND COAL,

are found in various localities, but not in sufficient quantity for any useful purpose.

PEAT.

"Of this useful, but almost entirely neglected combustible," says Dr. Beck, "we have already discovered numerous important localities; and many others will undoubtedly be added before the completion of the survey. The time cannot be far distant, when the value of this article will be duly appreciated. In many countries it is extensively employed as fuel; and in several manufactures it might be used with great advantage, as, for example, in the burning of bricks, limestone, &c."

As a fertilizing material for the soil, peat offers an almost inexhaustible supply, or at least the muck in our swamps, which more or less partakes of the properties of peat. It is vegetable food; but generally in an insoluble state. To render it available as vegetable food, the admixture with it of gravel or sand sometimes suffices; at other times it is necessary, in order to render it soluble, to bring it in contact with recent manures, lime, or other fermenting or heating matters. At other times, paring and burning the surface is the best mode of improvement—the action of fire, and the salts which the ashes yield, effecting a chemical change in its quality. Sometimes thorough draining of swamps induces great fertility. In all cases, we believe, it is profitably used as a bedding in cattle yards. It absorbs the liquids, is broken down and blended with dung by the tread of the cattle, and is thereby rendered completely soluble, and enriching to the soil.

CARBONATE OF LIME,

in most of its varieties, is found in many of the counties. The term marbles is confined to those varieties which are susceptible of a polish; and these frequently contain carbonate of magnesia, which, according to received opinions, renders them unfit for agricultural purposes, though they are mostly adapted to building purposes. Beds of marble are found in Westchester, Putnam, Dutchess, Columbia, Ulster, Albany, Schoharie, Oneida, Madison, Onondaga, Wayne, Niagara, Washington, Warren, Essex, Clinton, Franklin and St. Lawrence. In some of these localities the stone is white, in others grey, variegated, &c.

A great improvement, in the economy of burning lime, is mentioned in this report, which consists in the use of refuse screenings or dust of anthracite for fuel, instead of wood, and the employment of a perpetual kiln. It is stated on the authority of Dr. Jackson, that the lime burnt at Thomason, Maine, and "which serves to supply nearly all the cities on the Atlantic coast with the lime used in their buildings, and for agriculture," brings to that town alone half a million of dollars.

"Here, then," says the Report, "we have the singular fact, that fuel is transported from the city of New-York to Thomason, and the lime procured by its agency again transported to New-York Now, the lime thus obtained must be greatly superior to that which is produced from our limestones, or else our citizens have been strangely neglectful of their interest in this respect. I have reason to believe that the counties of Westchester, Orange and Dutchess, contain limestones which would yield lime equal to any elsewhere manufactured And with the improvements already introduced into our limekilns, as well as in those of Maine, one would suppose that our lime could be afforded at a much cheaper rate in the city of New-York, than that which is transported from a distant part of the United States. This subject commends itself to the enterprise of our fellow-citizens."

HYDRAULIC OR WATER LIME.

We have quoted the report on this subject, in another column.

GYPSUM, PLASTER OF PARIS, OR SULPHATE OF LIME.

"This important article, for which until within a few years past we were almost entirely indebted to Nova Scotia, may now be ranked among the great mineral products of our state.

"Gypsum, when pure, has a snow white colour, but it is often tinged with red, yellow, blue and grey, in consequence of the admixture of foreign substances. When crystallized, it is foliated, but it also occurs granular and compact. The foliated varieties are called *selenite*, while the compact ones are often known by the name of *alabaster*. It is distinguished from carbonate of lime by its being less hard, as it may be scratched by the finger nail; acids, when applied to the carbonate of lime, cause an effervescence, owing to the escape of carbonic acid—but no such effect is produced by a similar application to the sulphate of lime.

"The variety of sulphate of lime which is most abundant, is composed of sulphuric acid and lime, with about twenty per cent of water. Whenever it is used for architectural purposes, this water is driven off by the application of heat, the operation being commonly known by the name of *boiling*. The calcined or boiled plaster, when made into a paste with water, speedily hardens, and it is employed in this way for walls, for stucco, for taking casts of statues, in stereotyping, &c. Gypsum is moreover largely used in agriculture, and it is considered an invaluable fertilizer.

"Of this useful mineral, we have numerous and very important localities. They are, however, almost exclusively confined to the district bordering on the Erie canal. I am aware that it occurs in the counties of Columbia, Albany and Schoharie, but however interesting the specimens here procured may be for the cabinet of the mineralogist, the quantity is nowhere sufficient to answer any other purpose.

"The west end of the town of Starke, in Herkimer county, is the most eastern point at which gypsum has been found in any great quantity. According to Mr. Vanuxem, it occurs in white sandstone, the grey band of Mr. Eaton, and he represents it as being white and equal to the Nova Scotia both before and after calcination From twenty to thirty tons had been obtained by Mr. Crill, the proprietor, during the summer of 1837.

"In Oneida county, gypsum is found in beds of vast extent. It is sometimes pure, being foliated and transparent; but the largest proportion is dark coloured, and is mixed with carbonate of lime, constituting what is usually called *plaster stone*. This last is used for agricultural purposes, and when deprived of its water by calcination, as a cement.

"Localities of this mineral abound in the county of Madison. It is sometimes foliated and granular, but usually as in the above county, it belongs to the common or impure variety. It occurs imbedded in gypseous marl, every where forming irregular or somewhat rounded or conical masses rarely more than forty or fifty feet in diameter, and usually from ten to twenty feet in height These hillocks seem to be detached, and the conclusion is almost irresistible that they have been formed after the upper strata of rock have been deposited. The masses of gypsum are a foot or more in thickness, and weigh from four to six hundred tons. I can give no details concerning the amount of this mineral annually raised in this county, but in the town of Sullivan alone it is said to be from four to seven thousand tons.

"On the route from Chittenango to Syracuse, in Onondaga county, conical elevations similar to those already noticed, are of frequent occurrence; some of which have already been opened and found to contain deposites of gypsum, while others are left as the reward of future enterprise and labor.

"The interesting region around Onondaga lake, of which I have heretofore attempted to give an account, contains in addition to its other sources of wealth, some important deposites of gypsum. At Liverpool, the fibrous variety, then comparatively rare in this state, was found several years since, about twelve feet below the surface of the earth, associated with marly clay Recently the excavations made for the construction of the rail-road from Syracure to the Split-Rock quarry, have opened an extensive bed of the same valuable mineral. At this locality are to be found several varieties; as the foliated, the fibrous, the snowy, and the common or dark coloured—the whole imbedded in a kind of gypseous marl which effervesces freely in acids, and contains variable proportions of the oxide of iron. Gypseous beds, similar in their general character, also occur in the vicinity of Manlius, from which large quantities have been exported. But probably the most valuable deposites that have yet been opened up are those along the line of the Syracuse and Auburn rail-road, near the village of Camillus. We find here, among other varieties, noble specimens of transparent selenite, and what renders the locality peculiarly interesting, are the associated strata of calcareous tufa, and of the singular hopper form crystals of marly clay. From forty to fifty thousand tons of gypsum have been obtained simply from the excavations which were necessary for the construction of this road. And this may be considered as merely a specimen of what is still hidden in the adjoining hills.

"Beds of gypsum occur in various parts of Monroe county. Specimens of the foliated variety, with a rose colour, have been found below the Genesee Falls, at Rochester, and nodules of snowy gypsum are quite common in the calciferous slate at the same place. Gypsum is also obtained in small quantities in the towns of Pittsford, Riga and Chili; but, according to Mr. Hall, the workable beds of this mineral are almost wholly confined to the southern part of the county.—'Along the valley of Allen's creek and Mill creek, two miles north, most of the plaster of Monroe county is obtained. Both these places are in the town of Wheatland At present about 5,000 tons of plaster per annum are obtained from this town; of this quantity, 4,000 tons are used in Monroe Co.'—*Hall's Report for* 1838.

"In the counties of Cayuga, Wayne, Livingston, Ontario, Seneca and Tompkins, beds of gypsum have been found in various places; but I have no means of determining even the probable quantity which they yield.

"The localities of this mineral in Niagara county are of considerable interest to the mineralogist. At Lockport, beautiful specimens of transparent selenite and snowy gypsum have been found, associated with pearl spar, sulphate of strontian, and the rare anhydrite or anhydrous sulphate of lime. Snow white granular gypsum also occurs near the Falls of Niagara, with occasional specimens of foliated selenite of a fine sky-blue colour. At all these localities, the gypsum is imbedded in the geodiferous lime-rock of Professor Eaton, but it does not, to my knowledge, occur in quantities sufficient for useful purposes.

"A very imperfect idea of the quantity of gypsum which exists in this state, will be obtained from the sketch which has now been given. Even if we had the means of ascertaining exactly the number of tons at present annually raised, which I think cannot be less than 50,000, it should be borne in mind that regular explorations are seldom undertaken, and that the amount, whatever it may be, is mainly the result of accidental discovery, and of occasional labor by the farmer during the intervals of his other avocations. Immense beds still lie unopened, which will at some future day yield their treasures. Perhaps one reason why greater attention has not been paid to the enormous deposites of gypsum and marl which exist in the western part of the state is, that the soil is naturally so fertile as seldom to require the employment of those artificial means of renovation which in most other countries are necessary to the success of the agriculturist. Still it cannot be doubted that in many situations even here, much advantage would be derived from the use of these efficient fertilizers. Lime, marl and gypsum, all of which can be so easily and so abundantly obtained in the region in question, have almost entirely changed the agricultural character of the states of New-Jersey and Pennsylvania; but it appears to me that in no part of our state which I have visited, is the value of these articles duly appreciated."

"MATERIALS FOR THE MANUFACTURE OF PORCELAIN.

"The localities of clays suitable for the manufacture of brick and the common kinds of earthen ware, are too numerous in this state to be at present noticed, and their description belongs rather to the department of geology than to that of Mineralogy. Many of these have already been noticed in the reports of the geologists, and Prof Mather has presented some details which show the importance of the branch of industry included under the art of brickmaking.

"The manufacture of the finer kinds of pottery has not heretofore been carried on with much success in our country. Whether this be owing to the superior facilities which are possessed by the English and French in regard to materials, or to the reduced price of labor, it is not easy to determine. My present object is merely to show that New-York is not destitute of the materials necessary for this branch of art.

"The finer kinds of pottery require for their manufacture the purest clays—such as contain little or no oxide of iron and which consequently do not turn red in burning. To these a portion of pure silica is added, which is prepared for the purpose by heating masses of flints or quartz, quenching them in water and then reducing them to powder in a mill.

"Clays of a good quality occur abundantly in various parts of Staten and Long-Island, and upon proper trial they would no doubt be found to answer the purposes of this manufacture. There are also several localities in Orange county, where similar materials may be obtained.

"Near Southfield furnace, in the latter county, is a bed of decomposed feldspar, known by the name of porcelain earth, which will probably be of great value in the manufacture of pottery. This substance is of a pure white colour when dry, a little unctuous, and is supposed to be abundant.

"As for feldspar, used in glazing and also in the body of the finer kinds of pottery, we have several localities in Orange county, in Warren county, near Caldwell, and also in the counties of Jefferson and St. Lawrence; while quartz, of a good quality and in sufficient abundance for the same purpose, is found in Orange, Columbia, and other counties.

"Those who are at all acquainted with the history of the arts, both in this and in other countries, must be aware that their progress has oftentimes been extremely slow, and it will not be surprising if the manufacture in question, although now of so little value to us, should become an extensive and important one. Previously to about the year 1760, England depended wholly upon other countries for the finer kinds of pottery; the English ware being generally of an inferior quality. But in a few years after the investigations and consequent improvements of Mr. Wedgewood the current of importation of even the finer earthen wares was changed in that country to exportation, and their manufacture has at length become of such vast extent that it is not easy to calculate its value.

"So it has been with many of the arts now successfully prosecuted in our own country. A great number of articles, for which we were but a few years since entirely dependent on foreign nations, are now manufactured by our mechanics and in our own workshops."

THE BUDGET.

☞ A subscriber wishes Mr. Garnet's opinion of the best method of applying manures to land.

☞ Mr. Love's request will be made known to Mr. Pitts as soon as the latter arrives at Albany, which is daily expected.

ROOT SLICER.

We have received from our esteemed Lockport correspondent, J. E. a drawing and description of a root-cutter—the knife to cut both ways, fixed in a frame, which is to be moved by manual power, on a horizontal frame, backward and forward, under the hopper containing the roots. The objection to the machine would seem to be, that it possesses no economy or multiplication of power—but must be propelled by main force, without the aid of any of the mechanical powers, as the lever, wheel, &c. We have seen cutters which we deem preferable.

WILD GARLIC OR WILD ONIONS, &c.

A Staten-Island "Subscriber," asks directions for expelling wild onions, or wild garlic, from his fields, and of removing the taste of them from milk, &c. The wild garlic is a bulbous perennial plant, and is a troublesome pest in many districts of our country. It is as hardy as the Canada thistle, or quack grass, and as tenacious of life; and can only be destroyed, like the thistle and the quack, by preventing the growth and maturing of the top—which is effected by ploughing and hoeing during the spring and summer months—by spring crops. No plant can survive the growing season, without leaves, its elaborating organs.

We find in the Memoirs of the Philadelphia Ag. Society, several communications confirmatory of the above being an effectual mode of destroying the wild garlic.—We will cite the experiment made by Paul Busti. He ploughed his field early in the spring, which was infested with the wild garlic, and prepared it for Indian corn. Garlick came up, but was cut down and overturned by the hoe and plough, in dressing the crop. Few escaped unhurt. "Determined, however, that none should remain, and convinced by the simple reasonings of plain good sense, that the frequent stirring of the ground, [destruction of the leaves or tops,] must prove the best check upon the growth of any vegetable, I converted in the spring," says Mr. B. "the corn into a potato field, adding a good deal of manure. I may with truth boast, to have perfectly succeeded in subduing the garlic; for among the rye harvested this year from that spot, not a single seed of garlic was discoverable."

Algernon Roberts wholly destroyed the garlic in a field, by a succession, for some years, of spring crops, corn, oats and clover, accompanied by gypsum and manure.

To destroy wild garlic, says Cooper, a system of good farming must be adopted, founded on good manuring and fallow crops, (not fallows,) where the crop requires careful horse-hoeing.

Quack grass is destroyed by three or four years of close pasturing—because the cattle destroy the roots by keeping down the tops—but as cattle will eat the tops of neither the thistle nor star of Bethlehem, these can only be eradicated by tillage—by spring, by hoed crops.

To remove the taste of garlic or turnips in milk, it is directed, in the Domestic Encyclopedia, to pour into each gallon of milk, when it is fresh from the cow, one quart of boiling water. The flavor of the garlic and turnip being volatile, is set free and expelled by the heat of the water.

A Rev. Clergyman, who has recently located himself upon a farm in Pennsylvania, has described to us a "*pest*," which abounds in some of his grounds, and which he asks directions for getting rid of. He denominates it "*evergreens*," and his farmer "*ripple-grass.*" It grows in *bunches*, has *matted bulbous roots*, and spreads with great rapidity. He says he has seen this detestable weed cultivated in the east, in gardens, with great care. We suspect this "pest" to be the star of Bethlehem, (*ornithogalum umbellatum.*) Be it this or not, the only means of destroying it is that recommended for destroying the wild garlic, the Canada thistle, quack grass, or other perennial—by preventing, by means of the hoe and plough, the growth of the stem and leaves, the elaborating organs of the plant, and thereby starving the root, so that it will die.

POTATO OATS

Are highly commended by L. B. Nottingham, Eastville, Va. His neighbor, Dr. Kerr, from a shot bag full of seed, less than the twentieth part of a bushel, obtained, with ordinary management, three and a half bushels. Mr. Jaynes, another neighbor, raises them to weigh forty pounds per bushel, and sows this year three hundred bushels of seed.

DUTTON CORN AND ROHAN POTATOES.

A. M. D. Robertson, writes us from Rock River, Wisconsin Territory:—"Last spring, I procured one quart of Dutton corn, and three Rohan potatoes, from friend Thorburn, of Albany. I planted them in the Rock River soil. Both were planted late. The corn suffered much from the cut-worm and prairie squirrel; notwithstanding which the product was from sixty to seventy bushels the acre. Every grain is bespoken for seed. The three potatoes were planted in 18 hills.—They suffered much from the cut-worm. I dug them late in the fall, and I had a barrel larger than a flour barrel full, and three pecks over. It is a hard tale, but it is truth, every word truth. I could hardly have believed it myself, if I had not seen it."

J. E. Ferre, of Agawam, Mass. raised from one tuber, weighing six ounces, 34 lbs. Rohans, being sixty-eight fold.

TIME TO SOW CLOVER.

"When is the best time to sow clover seed, on a piece of loam, to he sown to winter wheat in the latter part of 9th mo. (Sept.) after corn?—*E. Mabbett.*" *Answer*—In April, upon the young wheat.

A DECENT PIG.

Lyman Smith, of Westfield, Mass. slaughtered a pig in March, which weighed when dressed, 791 lbs.

RELATIVE VALUE OF POTATOES.

A Columbia correspondent is puzzled to reconcile the various statements we have published, at different times, as to the relative value of potatoes and Swedish turnips for cattle food. He says ruta baga is stated to contain from seven to eight per cent of nutritive matter, and potatoes twenty-five per cent; that in the sheep report of Mr. Rotch, 200 lbs. of potatoes are deemed equivalent to 350 lbs. of ruta baga for sheep; and that in the conductor's report in our March number, upon the comparative value of roots for neat cattle, we stated, that it would seem there is no great difference in the feeding properties of the three kinds, viz. potatoes, mangold wurzel and ruta baga, so far as measure and weight are concerned. In reply to our correspondent, we can only say, that each of the authorities he refers to, that is, Davy, Wagner, and the Prize Essays of the Highland Society, are all highly respectable, and entitled to credit. Davy states the soluble nutritive matters of 1000 parts

Of the potato, to be.........	200 to 260
" ruta bag,....................	64
" red beet,....................	148
" white beet,..................	136
" parsnip,.....................	99
" carrot,......................	98
" linseed cake,................	151

Now every person who has had experience in feeding the above kinds of food, will know that linseed cake is more than twice the value of potatoes for fattening beef, although its nutrient properties are rated twenty-five to fifty per cent less than those of the potato; that the carrot is better for cows, and particularly for horses, than any of the other roots, or than oil-cake, although it ranks in the scale below most of them; that to the pig, the potato in its raw state is less nutritious than the carrot, the parsnip, the beet, or the ruta baga—indeed, that while a pig will thrive on any of the former, he will but live upon the latter, although the potato outranks them all in nutrient properties, from twenty-five to one hundred per cent; and finally, that what may be meat to one species of farm stock, may be poison, or at least may fail to possess fattening properties, to another species. We do not assume to reconcile the seeming discrepancies which our correspondent has pointed out, and still we are disposed to respect them all as good authority. We believe that animals, like plants, have their specific food; and that what is most beneficial to one species is not equally beneficial to another species. One kind of animal, like one kind of plant, will assimilate and retain some portions of food, which another kind of animal will void. There is still one other consideration which we will offer, and that is, that the potato differs one-half in its nutritive or fattening properties, which ranges, in different varieties, from fourteen to twenty-eight per cent. There is much yet to be learned pertaining to the "art and *mystery*" of agriculture.

Having thus endeavored to answer the queries of our correspondent, we beg, that in his next communication he will send us his name, though he should tax us with postage.

QUERIES.

1. *Is June as good a season to bud peach trees as August?* No—August and September are the best months, and stocks should be budded the first season of their growth from the seed.

2. *Is not budding better than grafting for that fruit?* Budding is decidedly preferable to grafting on the peach.

3. *Does it make any difference whether those of the same species are united, or of different species, i. e. clingstones upon clingstones, or upon freestones?* None at all. The peach may also be worked on the plum, the apricot upon the peach, some pears, (the melting kinds generally,) upon the quince, &c.

"*Studioso Evangeliis,*" is too sensitive. The term *producing* classes is applied, by common consent, to those who virtually create wealth by manual labor; and the term *non-producing*, or consuming classes, is used, in contradistinction to the other, to indicate those who do not live by manual labor. We make not war with the learned professions. They are all useful to a limited extent; but in some departments we have certainly an excess, or an undue proportion of these good folks; and our desire is to bring about an equilibrium in the commonwealth—not by depreciating the one class, but by enlightening and elevating the other, and thereby increasing their numbers, and their moral and political influence upon society.

WATER LIME.

"*What is water lime, and how is it prepared?—J. Chaplain.*"

We give the answer to the inquiry of our correspondent, in the following extracts from the report of Dr. L. C. Beck, from the Geological Report, just published.

"*Hydraulic or Water Limestones.*—It is well-known," says the Report, "that the lime obtained by the calcination or burning of the different kinds of limestone, differs greatly in its properties. When the limestone is pure, the resulting lime is also of uniform purity. Upon the addition of water to such lime, a high degree of heat is produced, its bulk is greatly increased, and it at length falls to powder. This powder, when mixed with water, and a due proportion of sand, and afterwards exposed to the air, gradually acquires a stony hardness; but this result is not produced when the mixture is submitted to the action of water. Now these are designated by the name of *air limes*, and their relative value depends in some measure upon the kind of limestone, and the particular mode of calcination.

"But certain impure limestones, when subjected to calcination, afford limes which, while they do not undergo much change by simple exposure to the air, do not slake when moistened with water, but when reduced to powder, absorb this liquid without producing much increase in volume, and without the evolution of much heat; and they moreover form with it a paste possessing little tenacity, and which when placed under water, hardens after the lapse of a few days —These are now known by the name of *hydraulic or water limes.* They differ much in the rapidity with which they harden under water, and in the degree of solidity which they ultimately attain.

"There are still other limestones which afford limes, possessing the remarkable and very useful property of becoming hard almost instantly, like plaster of Paris, whether exposed to the air or in contact with water. These are sometimes called *Roman Cements.* It should he remarked, however, that the French generally employ the term *ciment*, to designate fine pounded bricks or tiles; while in this country, the term *cement* is most commonly used in a generic sense, and includes the hydraulic constituent of mortars, whatever that may be.

"There is still some difference of opinion, as to which of the ingredients of these impure limestones, the hydraulic property is to be ascribed. Some of those who have examined the subject, have fixed upon the oxide of iron, as the important ingredient; while the claims of the oxide of manganese, silica, alumina, magnesia, and even soda, have each been urged by respectable authority. It is, after all, however, more than probable, that the hydraulic property is not due to a single ingredient, but belongs rather to several substances, or to a class of compounds.

"It appears, from the experiments of Berthier and Vicat, the highest authorities upon this subject;—that no mixture, of which silica does not form a part, acquires hydraulic properties,—that limes containing only silica or alumina, or better those containing silica and magnesia, acquire a much greater degree of hardness than the silicates of pure lime; and that the oxides of iron and manganese contribute nothing to the hardening of these bodies.

"More recently, M. Vicat has asserted, that magnesia alone, when in sufficient quantity, will render pure lime hydraulic. The proportions of magnesia which he recommends, are from thirty to forty per cent of it, weighed after calcination, to every forty of pure anhydrous lime. 'M. Vicat also points out the importance of these observations;—hydraulic lime never having been found in the calcareous formation below the lias, is because the dolomites have never been examined; but it is now probable that it may be found in this formation.'*"

"The mode of preparing the cement is sufficiently simple. The limestone is first reduced to small fragments, which are then thrown into a kiln, with layers of the screenings of anthracite intermixed. At an interval of of twelve hours, the lower layers of the kiln are removed, and fresh portions of the limestone thrown into the upper part. These operations are so managed, that each layer is subjected to heat for about three days.

"The lime thus calcined, is of a light drab colour, and when reduced to powder and mixed with about one-third its bulk of sand and made into paste with water, soon becomes hard. The grinding is performed in a mill, and the powdered cement is put up in barrels, which are lined with paper, to exclude as much as possible, the contact of air. The cement thus prepared, is sold at $2.25 the barrel."

Water limestone is found in the counties of Albany, in the Helderbergh; of Herkimer, Oneida, Madison, in most of the western counties, and particularly in the county of Ulster, in which latter place, upon the Rondout, and Hudson and Delaware canal, 3,000 barrels of this cement are manufactured weekly, a great portion of which is employed in the Croton aqueduct, and in the United States' works, near Boston. Dr. Beck gives the following analyses of the Ulster county hydraulic lime, the first set of figures showing the proportions in its natural, and the second set in its calcined state.

Carbonic acid,.................	34.30	5.00
Lime,..........................	25.50	37.60
Magnesia,......................	12.35	16.65
Silica,........................	15.38	22.75
Alumina,.......................	9.13	13.40
Oxide of iron,.................	2.25	3.30
Bituminous matter, moisture and loss,..........	1.20	1.30
	100.00	100.00

Acknowledgements.

From the Hon. James M. Garnet, of Virginia, a drill-barrow, which sows four rows at a time—of which we shall speak further when we have tried it. From Mr. Fitzhugh, Indiana, seed corn, a cross of the Tuscarora and Sweet or Sugar varieties, which we have planted. From George C. Thorburn, New-York, a bushel of the celebrated Whitington wheat, a plant of the Tobolsk rhubarb, the London Gardener's Gazette, and choice flower seeds. Several samples of Indian corn and other seeds, from different gentlemen. A sample of imported Italian wheat from J. Hathaway, of Rome. Several kinds of seedling potatoes, from John McLean, of Cayuga. Seeds from H. Collamore, Esq. Pembroke, Mass. Sample of premium corn, from W. Ingall, of Oswego. It is of the Dutton variety, beautiful—the ears eleven and twelve inches long, and well filled to the tips—twelve ears giving more than thirteen half pints of shelled corn. From the Rev. Mr. Colman, several valuable agricultural pamphlets. From J. W. Proctor, Essex Agricultural Society Transactions; from T. H. Webb, Dr. Jackson's Geological Reports, and other pamphlets.

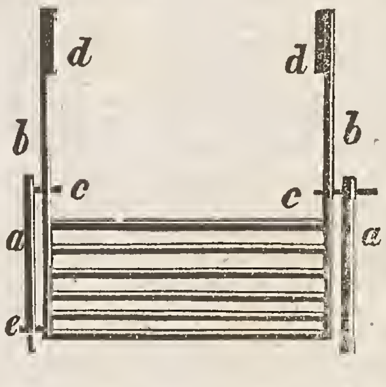
CORRESPONDENCE.

The Revolving Gate.

Norfolk, Litchfield co. Ct. March 5, 1839.

Mr. J. Buel—Sir—I feel a great reluctance to write for an agricultural paper like yours; but feeling it a duty to impart instruction as well as receive it, I herein will attempt to describe a kind of gate that I erected last summer, which I shall term the revolving gate. It is made as follows, viz:—Set two posts, 5 feet 4 inches high from the ground; let the top of the posts incline a little inward, so that the gate will not shut against them; bore a hole in each post 4 inches from the top, and mortise from the hole upwards, to receive the pin or axis of the gate, or the abutments of a stone wall may be substituted for posts. Take scantling say 10 feet long, 3 inches square, for uprights; frame slats, boards or poles into one end of the uprights, to the height of 4 feet; bore a hole in the centre of each upright for the pin or axis, which may be made of wood or iron.

[Fig. No. 13.]



I send you a drawing of this gate, the better to enable you to understand it.

a a Posts. *b b* Uprights. *c c* Pins, or axis of wood or iron, on which the gate revolves. *d d* Weights to balance the lower part. *e* A pin to fasten the gate.

The top of the uprights ought to just balance the bottom or gate part, either by large but ends, or by adding weights. A gate of the above description will swing up 6 feet in the clear. The only objection to this gate is, it will not receive a high load; this may be remedied in two ways—1st, by making them light, so that two men will take them out with ease; or, 2d, the posts may be made higher. If the gate is 4 feet high, and the axis is 8 feet high, the gate when it revolves will be 12 feet in the clear—but I should prefer the former.

The advantages of these over ordinary gates are—

1. They are cheap—they need not cost much if any more than posts and rails, and in the long run are much cheaper.
2. They are very simple, as any farmer can make them without the help of a mechanic.
3. They require no bracing to keep them from dragging.
4. They will not pull over the posts.
5. They are not liable to get out of repair by sagging, or being blown by the wind.
6. When opened they do not form an angle for cattle to run behind.
7. They are not liable to be opened by unruly cattle, and if properly balanced, a child will open them.
8. They will open more handily, when the snow is drifted about them.

---

* London & Edinburgh Philosophical Mag. 3d series, VIII. 591.

9. If an awkward teamster drives a cart against one or both sides, (as some will,) if slightly fastened, he merely shuts the gate after him.

This gate may be fastened shut or open, by a pin or catch near the bottom. Respectfully yours,

HORACE HUMPHREY.

Draining.

Although much has been written on this subject, enough, one would suppose, to convince any agriculturist of its utility, and instruct him in the best mode of performing the operation; yet hundreds of dollars are annually thrown away by injudicious draining; and we deprive ourselves of other hundreds, by not draining at all. I have mowed two or three acres of land, (or rather of mud,) some ten or twelve years, and the hay, (if hay it may be called,) has hardly paid the expense of mowing. A line of springs breaks out along the upper side, the waters of which, slowly meander to a neighboring creek. Three or four years ago, I undertook draining, knowing, perhaps, as much about it as some of my neighbors, and practising full as well. I cut ditches from the springs directly to the creek, say eighteen inches deep, and shallowly left the shallow things open for the frosts of winter to fill: but the sequel proved that all was not right; for my meadow was ne'er the better for all my labor. But thanks to the Cultivator for a better system. Last fall I undertook again, with about half an acre for an experiment. I ordered a drain to be cut two and a half feet deep, and two feet wide, from the creek to within a rod of a fine living spring, in the line of my orchard and meadow, (which spring I did not want to injure,) and then branch off to the right and left along the dry land. By digging this depth, we cut through the clay subsoil, into gravel, when we came into which, ever and anon a vein of water would tell us, that all was going on well; and it went well enough till we came to within a little over a rod of the spring, and then it went quite ill; for all at once, the water gushed up from the bottom of the drain, and away went my fine spring; and two others, one two, and the other three rods distant, were dry in fifteen minutes. Whilst we were digging, some of my neighbors, knowing my intention, advised me by all means to leave the drains open; but I was just stubborn enough not to mind them; for I first flagged the bottom of the drains with flat stones, well fitted together. I then placed narrow stones on each side, and flat ones on these; then filled with small stones to within a foot of the top, then inverted the sods on these, and finished with loose earth. I then tore up the hassocks with a plough, dried and burned them, and spread the ashes; sowed the ground with timothy seed, covered it with manure, and scarified it with an iron toothed harrow. What the result will be, time only can show; but this much I know, the ground that, last summer, dry as it was, would mire a team, is now dry enough to plough, and the timothy looks well.

S. HEATON.

Plattekill, Ulster, 4th mo. 8th, 1839.

Theory in Farming.

Near Brownsville, Pa. December, 1838.

Hon. J. Buel—This has been pronounced an age of improvement, and very truly; but while the mechanic arts have been brought to a high degree of perfection, and improvements in them widely and rapidly disseminated, agriculture, though it has made great advancement in some places, in others remains almost stationary. Now, what is the cause of this difference in these two branches? It would seem to be that mechanics have greater advantages for becoming acquainted with, and appreciating the value of distant improvements in their business; while farmers, from their habits and other circumstances, are forced to rely on themselves for improvements, or at most are confined to their own vicinity; consequently, improvements are slowly disseminated. The only remedy for this evil is to establish some channel, by which improvements, made in one section of country, may be communicated to the others. This channel, is books or agricultural papers. But against book farming, exists a long established prejudice; and the mere mention of theory in farming excites in the farmer a perfect abhorrence; but with what justice, let us further inquire, as it is a matter of great importance. A theory is nothing more than the conclusion at which we arrive after examining the laws of nature. If we understand these laws correctly, and form our theory accordingly, our theory will be correct; if not, it will fail. Every man (farmers included) forms a theory, or in other words, a plan, before he commences any operation. Watt, with his steam engine; Arkwright, with his spinning jennies; Davy, with his safety lamp, and Archimedes, with his mirror; each, made himself correctly acquainted with the laws of nature, on which he wished to operate, and on these, based his theory. Now, in these cases, had there been no theories, there would have been no inventions. But, as theory is admissible in the mechanic arts, why not also in agriculture? Nature is as uniform in her operations in one case as in the other. If the chemist tells us that alkalies neutralize acids, and that lime possesses the properties of an alkali, and if we know that some acid exists in the soil, is not the conclusion legitimate, that the soil will be corrected by the application of lime? This now, is mere theory; yet, we would feel justified in relying on it as strongly as though it were demonstrated. If also, as Davy has shewn, certain gases serve as the food of plants, and these same gases are given off during the fermentation of manure, who would not repose perfect confidence in the theory which would bring these gases in contact with the plants rather than permit them to escape into the air? Draining, also, might be cited as a complicated theory; but on that account, none the less certain in its results. In fact, nearly the whole routine of farming is theory. 'Tis true, many errors are committed in theorizing, but these must be laid to the ignorance of the theorist, and not to the system by which he attempts to arrive at that conclusion by his reason which he cannot reach by sight and touch. But our farmers tell us they want something "practical," and if we should hand them the Cultivator, and tell them it contains the experience of its correspondents and contributors, it will be denounced in round terms as mere book-farming, which deserved no credence, because forsooth they had not seen it. As though they would discriminate between what their neighbor told them viva voce, and that which he communicated to them by his goose-quill. This reminds me of the oriental despot, who dismissed from his empire, as a liar, an ambassador, who told his celestial majesty, that in his own country, water became in winter so hard that armies passed over, for the sage reason that he had never seen the like. While this old prejudice, and the ignorance on which it is founded, and which forms its chief support, remain like ramparts, to stop the wave which is making in our favor, how can we expect to be carried forward to that glorious goal to which we seem destined?

G. E. H.

Farm Buildings.

Plattekill, Ulster co. 4th mo. 8th, 1839.

Friend J. Buel—Among the many appendages to a farm, and the means of facilitating the labors of husbandry, I consider convenient buildings as holding a conspicuous place; and notwithstanding many plans, with different degrees of merit, have graced the columns of the Cultivator; yet I offer the plan of a small building I have lately erected, which, to publish or to be thrown aside with other waste papers, is discretionary with thyself.

[Fig. No. 14.]

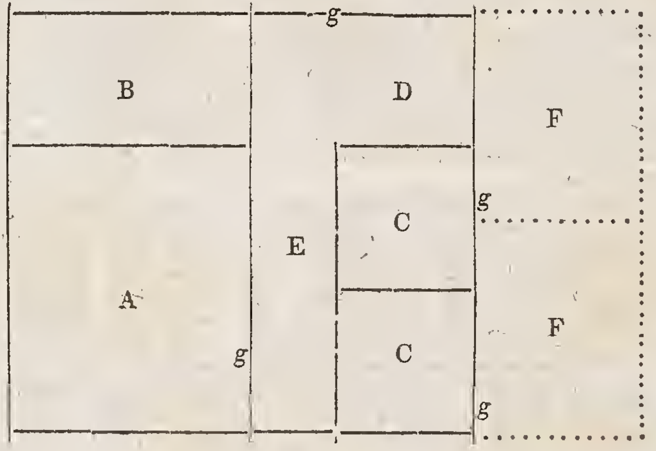


Fig. No. 14, is the ground plan of the building, which is erected on a side hill. A, is a cellar 14 by 16 feet.—B, a space between the cellar wall and the north foundation of the building, filled with earth. C, C, hog-pens, 8 feet square. D, a room for boiling food for hogs, and communicating with the cellar by the alley E. g, g, doors. F, F, yards.

[Fig. No. 15.]

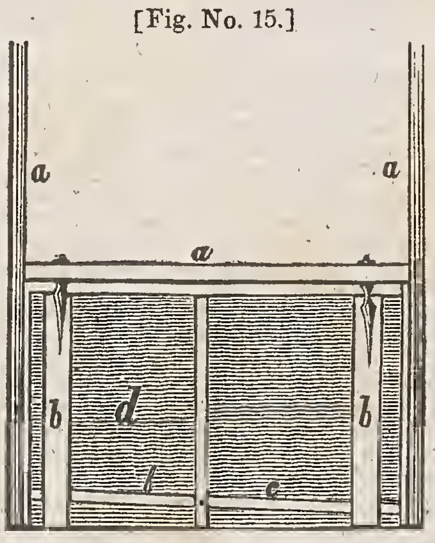

Fig. No. 15, represents the partition between the alley E, and one of the pens. *a, a, a*, the frame; *d*, a door; *b, b*, brackets; *c*, a latch, made fast at *f*, by a bolt; *g, g*, hinges. Under this door, is placed the trough; a piece of board 6 inches wide is nailed to each post, one directly over, the other beneath the latch; in these boards are two notches to receive the latch, so that in two seconds I can shut the hogs from the trough, and have it open to the alley, by lifting one end of the latch out of the notch, and pushing the door back to the opposite side of the trough; when it falls into another notch, the other end fastening in the same way above. This done, I can fill the trough without having to combat the greedy animals, and they have an equal chance after the door is swung back to its place.

Over the cellar, is a building 20 by 24 feet, 14½ feet posts, for a carriage house below and granary above; over the hog-pens, the roof of which is low, is room for housing sleds, tools, &c.

Now the advantages of this building are these—First, I have much room under a small roof;—second, I can draw my potatoes into the carriage-house, and shovel them through a trap-door into the cellar, without having to carry them in a basket, as I always have done, and many still do;—third, the cellar is on a level with the swill-house, or boiling room, so that there is no lugging them up stairs;—fourth, I can, by placing my feed tub in the cellar, boil potatoes for my pigs in cold as well as warm weather.

S. HEATON.

American and British Agriculture Contrasted.

As a large amount of our scientific knowledge of agriculture is derived from British works, let us inquire how far the system adopted there should be modified so as to suit our circumstances; for difference of circumstances renders a difference of system necessary. Many considerations are necessary to be taken into account, in order to determine the relative value of different systems of agriculture; and that one adopted, which suits best the respective circumstances of each. The agriculture of China would not answer for England; nor is that of England, in all respects, suited to the United States. For, first, the rent of land there is exceedingly high; consequently, it becomes necessary that every acre shall produce to the full extent of which it is capable. This high rate of rents is owing to a superabundance of competitors, and but a limited supply of land. There, land is the chief article of value, and hence the chief object of attention; hence a greater outlay would be justified on the same extent there than here. Secondly, on the contrary, in this country, labor is the great article of value. The comparatively low rate of wages in Great Britain, enables the farmer to make improvements which would never compensate in the United States. There, it enables him to bestow more care upon, and work more frequently and thoroughly his soil. We cannot adopt the system of England, for the same reason that she cannot adopt that of China, viz: difference of wages; for best imformed agriculturists are aware that we cannot bestow the same labor on the same object as the English. There is a medium point beyond which the extra profit does not justify the extra labor. This point changes with the change of circumstances. With us it is exceeding low. Thirdly. In England, the superabundance of capital, and low rate of interest, enable the farmer to make those improvements, and farm to that perfection, which would not be justifiable in the American farmer. Many of our farmers can appreciate the value of improvements, but their means are yet too limited to advance with the gigantic strides of the wealthy farmers of England. Grain does not bear the same price here as there. This high price of agricultural produce, and consequent profitablenes of the business, furnish both the inducement and means of improvement. This flourishing state of agriculture arises from legislative encouragement; large proportion of consumers to producers, and great facilities for transportation and exportation; in all which, we are far their inferiors.

All these causes co-operating, suggest that we should adopt a somewhat modified system, until the obstacles which impede our course, shall be removed. Yours respectfully,

G. E. H.

Mode of applying Manure—Antidote to Grubs.

Sing-Sing, April 17th, 1839.

Friend Buel—I frequently notice in the Cultivator, that your advice to farmers respecting the application of manure, to tillable land is, to apply it in the spring for hoed crops, by burying it with the plough to the depth of the soil; and you do not seem to admit of any variation on account of the different kinds of soil. I admit that where the soil under cultivation is dry, it may be best to manure for hoed crops,* and that it should be incorporated with the soil, but not buried very deep. (I write this, under the supposition that farmers, in this country, do not make manure enough, to apply it more than once to the same land, in the course of a rotation of crops.) But there is another description of soil, which, if ploughed at all, should be manured in the fall for the winter grain crop, in preference to any other. I allude to soils naturally moist, and particularly to those underlaid by hardpan; first, because on such soils, without manure near the surface of the ground, winter grain and the young timothy, is apt to freeze out, besides making it very uncertain for clover, the year following.

The rich juices of the manure, in the fall and spring, leach among the roots of the plant, giving it strength and vigor. By being light and spongy, the soil does not settle away from the roots of the young plant after a frost, as does the earth alone. Again, it is all important to most parts of the country, to keep the soil in a state of progressive improvement. If the manure be applied in the spring to a hoed crop, and after that we take two more crops of grain before seeding, we leave heavy land, but little if any better than we find it. And the succeeding grass crops, on which we mainly depend for the means of enriching our land, are sadly deficient in quantity. If we manure in the fall for winter grain, the succeeding crops of grass will be heavy, and when the ground is again turned up for corn, it will bring, I think, as good a crop without, as it would the time previous with manure, and that too, without deteriorating the soil to the condition in which the manure first found it; then our stock of manure on hand may be applied to enrich another piece of ground. If at the commencement the land is too poor for corn without manure, do not plant it, but summer fallow and sow winter grain, and manure at that time, for the reasons above stated. Now for the proof: a few years since I had two pieces of stiff clayey soil broken up, they were both poor and covered with moss, one I summer fallowed and sowed with wheat and grass seed, after spreading about twenty loads of manure to the acre on the furrow and harrowing it in with the wheat; in the spring following, I sowed it with clover seed. On the other I spread about twenty loads to the acre on the soil, ploughed it in about three inches deep,* (the depth of the soil,) and planted it with potatoes, had a tolerable crop, took them off and sowed rye, and seeded as I did the first piece; the result was, that I had from the first, full fifteen bushels wheat to the acre, the next year an abundance of clover, and for two years more, clover, timothy and red top, about two tons to the acre, and is now rich enough to bring good corn without manure. From the second piece I had about four bushels rye to the acre, hardly a spear of clover, and something like three-fourths of a ton of grass to the acre, and is to all appearance as poor as when I broke it up.

---

* We contend that no hoed crop, except potatoes, should be planted upon any but a dry soil—and that even potatoes should not be put upon a wet one. Under, or furrow draining, will render any soil dry, where there is a sufficient declivity to drain off the water.

We well know that the enriching properties of unfermented manure will leach away, thus where it is applied to grass grounds before the spring rains, the effect on the grass is surprising. May not its virtue, when buried beneath the soil, leach still farther down, and is it an expensive way of enriching a subsoil without the aid of the sun and atmosphere? Heavy soils are seldom managed as they should be. It would generally be better to plough but little and manure that highly, and top dress the remainder to renovate the grass, rather than plough much and risk getting any thing, besides toil and trouble. I will add, that in summering manure, I make it into a compost.

I have been informed by a friend, on whom I can rely, that to arrest the ravages of the grub in corn, as soon as you find they are troubling it, take tobacco, add water and boil it up until the decoction is strong enough; pour about a wine glass full on each hill; the remedy will be effectual, the cost trifling, and there is the consoling reflection that a filthy weed is applied to some good purpose. Yours, &c. JESSE RYDER.

Transplanting—Protecting Brick and Stone Walls—Culture of Onions.

Stockbridge, April 27th, 1839.

Mr. Buel—Although not a subscriber to your paper, I have received so much pleasure from it, that I feel bound to make a return, if it is in my power.

I fancy I can write upon two or three subjects on which your correspondents are soliciting information. I begin with the letter of Mr. Seitz, in the Cultivator of March. I beg to tell him that I have transplanted roots, such as sugar beet, ruta baga, borecole and mangold wurzel, with the greatest success for ten years past. I prefer it; but I must be candid, and tell you that they consider me here as an enthusiast. I prefer it, because I raise the young plants with the greatest care in my garden, so as to make them a great deal more thrifty than they would be in the lot. They are placed in the very best soil; highly manured; and if a drought comes on, are watered. Young plants, like young animals, require to be taken great care of; if this is well done, half the toils of agriculture are accomplished. Again, I have great time to prepare my soil, to carry out my manure, and to make the necessary arrangements for after culture; if this is well done, there is no danger in transplanting. I place a garden line to mark my rows; I give a scratch with the fingers, joined together, in the loose soil, and the root is deposited in a reclining position; this is the German method where mangold wurzel is cultivated in the highest perfection.

A gentleman from Morristown, in the same paper, inquires as to the best method of protecting brick walls against a driving easterly storm. I came here from India, where we have six feet of rain in four months; it requires some attention, in the art of building, to protect you against such a climate. Many houses have a broad veranda which brings the roof within nine feet of the ground; this makes the body of the house dry; but I had, what is called there, a top sail house; that is, two stories, to protect my walls, which were substantially built of stone, and well stuccoed. I had a projecting roof of near six feet. Nobody can imagine the comfort of allowing your windows to be open during a heavy storm of rain. A long driving storm will make brick walls damp; but this dampness is greatly increased by the sheets of water which perpetually fall from the roof. My house, in Stockbridge, has a roof of four feet projection, and I have received great advantages from it. The greatest expense in building, are sashes, blinds and window frames; these are well protected, and will last much longer.

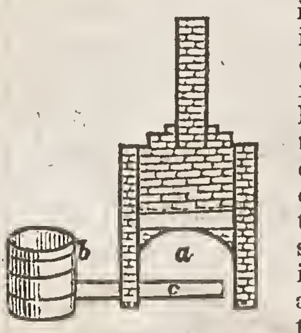
Now, to the third subject. I was amused at some inquiries I saw, from a gentleman from Pennsylvania, on the subject of onions. In Bombay, where I lived the greater part of my life, this root is cultivated in the highest perfection. The mode of cultivation was no doubt carried there by the Portuguese, who, with the Spaniards, produce a fruit that we know nothing of here. It sells in the markets of London, for fourpence and sixpence a piece. The fruiterers keep them in their stores; it is remarkable for its great mildness; the great perfection of the root depends on irrigation and very high manuring, which, by the way, can be used only with irrigation; the seed is sown at the end of our rainy season; when that is over, the ground is prepared by having beds made about six feet square, so as to contain about four inches of water; gutters pass between two rows of these squares. The young onion plants are pricked into the mud, and well manured; during the growth of the plant it is enriched three times, with powdered fish, and in less than three months the crop is brought into market. I have succeeded in this country in producing an onion equal to what I have seen elsewhere; but the climate here is too cold and too uncertain, and the season too short. In Pennsylvania, this would be a branch of industry from which important results might follow. Yours respectfully, L. ASHBURNER.

Boiler for cooking Cattle Food.

Hardeman's Cross Roads, Tenn. April 1st, 1839.

Judge Buel—Sir.—For several years past, I have been much more in the habit of attending to my farm, than writing, but as my paper and pen are before me, I will give you a description of my neighbor Bostick's boiler, which he uses for the purpose of boiling food for his cattle and hogs. It is simply a cast iron pipe, about five inches in diameter and six feet in length, closed at one end and open at the other end. It is fixed in the fire place of the kitchen. By placing it across the fire place, next to the back, on the hearth, and the open end of the pipe extends through the jamb of the chimney about six or eight inches, and passes into a tub or trough, which has a circular hole cut into it near the bottom for the reception of the pipe, which is prevented from leaking, by being corked around with tow. Then by putting water into the tub with corn, or whatever kind of food you wish boiled, and making a fire in the kitchen (which is usually done in this country three times during the day) the pipe becomes very hot and causes the food to be boiled very done.

[Fig. No. 16.]



It surpasses any thing of the kind I have ever seen, on account of its simplicity, convenience and economy of fuel; for we are necessarily compelled to have a fire almost constantly in our kitchen for cooking, and the same fire will serve, with this kind of a boiler, to cook food for hogs or cows, by which plan, they are kept in much better order and at much less expense, during the winter season. Your obdt. servt.

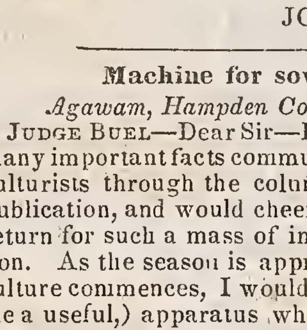
JOHN S. CLAYBROOKE.

Machine for sowing Beet Seed.

Agawam, Hampden Co. Mass. March 30th, 1839.

Judge Buel—Dear Sir—I feel myself indebted for the many important facts communicated by my brother agriculturists through the columns of your very valuable publication, and would cheerfully contribute my mite in return for such a mass of important practical information. As the season is approaching in which the beet culture commences, I would describe a simple (but to me a useful,) apparatus which I have made use of for two seasons past, for sowing all kinds of beet seeds. We sow on drills or ridges, which after they are thrown up with the plough we brush on the top slightly with a hoe, or head of a rake, to obtain a flat surface on the centre of the drill; for forming the drill to receive the seed we use a wheel made of plank 1½ inches thick, and 1 foot 2 in diameter, bevelled on each side of the circumference to nearly an edge in the middle, hung to turn on a pin between 2 handles, about 4 feet in length, which project forward of the wheel four or five inches; near the end a piece is framed in or nailed on to each crosswise in front of the wheel, in which is inserted a small wood or iron coulter or scratch on a line with the track of the wheel. The wheel is run upon the centre of the drills, and makes an impression or furrow 1½ inches deep and about the same width at the top, slightly compressing the earth at the sides and bottom of the drill, causing it to retain moisture, so essential to the germination of seeds. The drills thus prepared, we use the following machine for sowing, and equally distributing the seed.

[Fig. No. 17.]



A, a staff or handle 3 or 3½ feet in length, running through the flat piece B. B. six inches, and terminating at the lower end in an egg-shaped point or pivot; C. a pivot at the opposite end of the piece B. B. 6 inches long and shaped at the lower end like the former; *e e e e* 4 tubes with a half inch hole through the centre 20 inches or more in length, funnel shaped at the top (which may be formed of paste board or leather,) running through and fastened into the piece B. B, to extend about three inches below said piece; *d d*, a strip of lath ½ an inch wide, tacked to the tubes to keep the tops in their places. The tubes are six inches distant from each other, and the 2 outside ones 3 inches from the pivots. The machine we use is made of white pine, tubes and all (tin would be preferable for tubes,) and weighs 2½ lbs. and was made by myself in less than 2½ hours. After the seed is prepared by soaking, or wetting and rolling in plaster, or ashes, to fill their rough surfaces, that the seed may separate more readily, the machine is set up, the pivots in the drill, and a seed is dropt into each tube; it is then turned from the workman towards the right on the front or short pivot into the drill again, and a seed is dropt into each tube as before; it is then turned on the handle pivot, and so on alternately, dropping the seeds at each turn, &c. The workman can stand upright in the space between the drills, and the tubes being so near the ground that the dropping is not affected by the wind; the seed lies regular at 6 inches apart at the bottom of the drill; with a little practice in taking about the requisite number of seeds so as to separate freely, from the planting pocket, a person will drop at a decent walk, without much fatigue. We cover with the head of a rake run along back down nearly lengthwise the drill; if the soil is light and dry, run a hand roller over the rows of about 6 or 8 lbs. weight.

We also make our drills for ruta baga, with the before mentioned wheel, and sow the seed from a small tin box fastened to a staff or handle 3 ft. in length at angle of 45 deg. downward, having 2 holes to let the seed pass out in the lid, which when the handle is held upright is the bottom, filling the box half full of seed and holding it in the left hand over the edge of the seed drill, and rapping the box gently with a light rod in the right hand, a person will sow at a brisk walk with great regularity. Last season I sowed one quarter of an acre in this manner with less than 1½ oz's seed, and they required considerable thinning after they came up.

I obtained from the Albany seed store, last spring 1 Rohan potato, weighing 6 oz. planted it on a dry sandy soil, where it suffered severely from drought for two months; the produce however was 34 lbs. many of them good sized tubers, and a few that grew very late in the season quite small—I have 6 hills in boxes growing in the green house planted about the middle of March, which I design to transplant in the field at the proper season, (the boxes being slightly made for that purpose.) The object is to see if very small tubers of that variety, if sprouted early, by artifical means, will produce large ones. The 2 tubers to make the 6 hills did not weigh one ounce in all. I may give you the result hereafter.

Yours with esteem.

JONA. E. FERRE.

Physiology—Vegetable and Animal.

Dear Sir—In another number of the Cultivator you published my communication relating to the artificial crossing of vegetables, &c. which imitates, partakes of, and has an alliance with, the animal kingdom.

I have frequently met with insects in a dormant state, and at first supposed them to belong to the vegetable kingdom, and the first glance of the elephant only resembled a heap of inanimate matter. If we saw a tree approaching us we should suppose it to be an animal, but if it remains stationary, not possessing any muscular power, it is ranked among the vegetables, though it possess most of the properties of some animals.

The vegetable nor the animal can subsist without food, and upon the quantity and quality depends the health of both; either may be injured by food not adapted to their habits, their appetites or digestive powers.

Animals subsist most entirely upon vegetables; it is through the vegetable kingdom that the different properties of the earth are subtracted, suitable for the support of the animal kingdom; hence the vegetable forms the link between the animal and mineral, or inanimate nature.

I propose to add more respecting the structure of plants, and on the general analogy of vegetable and animal life; and I shall endeavor to notice that which may be useful and interesting to the reader, by referring to Good's Book of Nature for the ground work of the subject.

In the organized bodies and the structure of plants, compared with that of animals, I would first ask, where is the difference between the stone and the plant? If one be removed to another place it will suffer no alteration, by change of place; but as soon as the other is removed it will instantly sicken, and perhaps die. Both have proceeded from a nucleus or germ; both have a tendency to preserve their family configuration; and both have been augmented and perfected from one common soil. It is only by a minute attention to the relative histories, internal structures and modes of growth of the two substances, that we are enabled to offer any thing like a satisfactory answer; and by thus examining we find that the stone was produced by chance, and has grown by external accretion, and can only be destroyed by mechanical or chemical force; while the plant has been produced by generation, and advanced in size in proportion to, and by the nourishment it has received, and destroyed by death; its parts have been mutually dependent and contributory to each other's functions. The consistency of the internal power is unknown; differently modified, we meet with it in both plants and animals; and we denominate it *the principle of life;* and the substance thus produced is called an *organized being.*

The various bodies of nature arrange themselves under the two divisions of organized and unorganized; the origin of the former by generation, the latter a fortuitous origin. The corals, sponges and fuci form the lowest natural order among animals and vegetables; the corals seem to constitute the link that connects the animal and vegetable with the mineral world; it has, in different periods, been ascribed to each.

The difference which consists between the organization of the animals and the vegetables is not very clearly marked out, and we characterize them more by description than by definition. We can readily distinguish the difference between animals and vegetables in their more perfect states; we find the plant confined to a particular spot, its nourishment derived from the same, and presenting no marks of consciousness or sensation; we behold the animal capable of moving at pleasure, exhibiting marks of consciousness and sensation; and a very high degree of intelligence ofttimes. Yet, if we should only lay down consciousness or sensation and locomotion as the two characteristic features of animal life, we should find our definition untenable; for while the Linnean class of worms affords instances, in perhaps every one of its orders, of animals destitute of locomotion, and evincing no marks of consciousness or sensation; there are various species of plants that are strictly locomotive, and that discover a much nearer approach to a sensitive faculty. Therefore the distinction between the animal and vegetable life, in their most striking form, fades away as we approach the extremities of the two kingdoms, where the mutual advances are so close and intimate that it becomes a task of no common difficulty to draw a line of distinction between them, or to determine to which of them an individual may belong.

---

* A three inch stratum of soil, especially with a tenacious and wet subsoil, cannot be expected to produce much of any crop, especially of tap-rooted plants, like clover, with or without dung.

Therefore when we give a distinctive character for animals and plants, we are compelled to resort to, and derive it from the more perfect of each kind; and to leave the extreme cases to be determined by the chemical components eliminated on their decomposition.

Yours, S. W. JEWETT.

Weybridge, Vt. May, 1839.

Culture and Profits of Squashes.

Narrows, L. I. April 24th, 1839.

Mr. Buel—There are several varieties of squashes cultivated for the supply of the New-York markets, but the early white scollop-shell bush squash, is the one principally in vogue. This variety, although more profitable to the cultivator than any other, is not, however, the best for the table. We have a small striped squash, shaped like a heart, which is more dry when cooked, and far preferable in flavor. This last variety came originally from the vicinity of Schenectady, (about forty years ago,) and has since been kept pure by a few individuals. They are ripe about a week later than the first named variety, and are not fit to be pulled until they become so hard that the finger nail cannot indent their shells; they will remain on the vines without spoiling until frost appears in the fall. Probably the reason why the striped squashes have not come into more general use, and why the white ones continue to hold the ascendancy, is, our demanding the same or a higher price for them, although much smaller in size, and the fact that many of the citizens of New-York prefer quantity to quality. I have never known the seed of the striped squash to be sold in the seed stores, and have often been disappointed in purchasing what was labelled for the white scollop-shell, for the produce, instead of proving to be white, I have found to be yellow, although the papers had the usual marks of the Shakers on them.

The cocoa nut and the grey and white long neck squashes are excellent for fall and winter use, but not much cultivated in our vicinity.

The reason why many of the squashes sold in the markets are poor, is their being gathered too green, the cupidity of the cultivators inducing them to pull all that are of a good size, without reference to ripeness, so as to have them for sale as early as possible, to command the highest prices.

Squashes, like many other vegetables, will grow on almost any good soil, but a rich sandy loam with a red clover sod, on low ground, is preferable, and in such a situation, with proper management, they seldom fail.

For early squashes, in the beginning of April, (if the frost has disappeared,) we spread over the ground about thirteen two horse loads of street manure to the acre, immediately plough, harrow until mellow, furrow into hills five feet apart, and place three-quarters of a shovel full of the same kind of manure we use for cucumbers and melons into each hill, which is covered with earth about an inch deep: we then drop from fifteen to twenty seeds into the south half of the hills, (scattering them so as not to have the plants crowded,) and cover with fine earth an inch and a quarter in depth. About a fortnight after the first seeds are put in, we plant over, in the north half of the hills. Formerly I was not in the habit of planting over, excepting such hills as were deficient in plants, but experience taught me in 1834, the necessity of it; for on the 26th of April, after the plants were all up, a black frost swept them clean: by planting over, therefore, a greater certainty is insured of an early crop, which in the markets is of great importance.

Squash seed is far more hardy than that of cucumbers and melons, and will remain a long time in the ground without rotting. They require a rotation, and do not prosper two years in succession on the same ground.

The after culture of the plants is the same as that of cucumbers and melons, except ploughing between the rows when planted on sod at the first hoeing, and using the cultivator at the others. The plants are gradually thinned down to three in a hill, and the last hoeing is given a few days after the blossoms open.

The plants, like others of a similar nature, are liable to the depredations of black worms and yellow flies: it is a singular fact, that the latter often select a single plant in a hill and feed upon it in swarms, while the remaining ones remain untouched. I have frequently known single hills, and occasionally a large portion of some patches of squash plants very much injured, and sometimes destroyed, by a species of aphis taking possession and affixing themselves to the roots of the plants; they are about as large as a pin's head, of a green colour, and when the ground is carefully removed they are found adhering to the roots and stem. Plants infested by them in general either remain stationary or else gradually pine away: those that recover never afterwards flourish. I am unable satisfactorily to account for their appearance, but suppose them to be derived from the manure.

Squash plants on good ground continue in bearing until the frost in the fall destroys them.

Cocoa nut and long neck squashes require to be planted in hills eight feet apart, and at planting, a dozen seeds in a hill are sufficient.

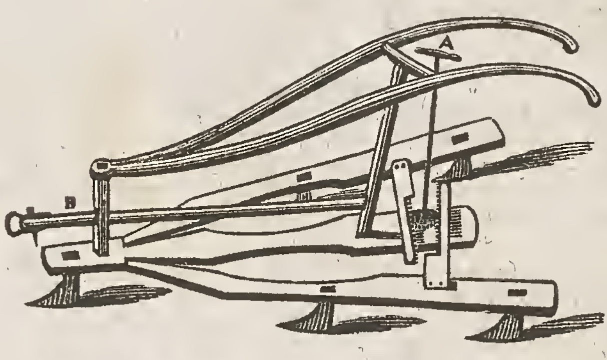
The following is the number of hills planted, produce, (unsaleable ones excepted,) and amount of sales for the preceding four years, viz:—

Year,	Hills planted.	Dozen sold.	Am't rec'd.
Of early white scollop-shell squashes,			
1835,	1,482	851	$179 82
1836,	1,482	1,146	372 00
1837,	1,590	858	167 86
1838,	1,554	780	208 25
Of striped shell squashes,			
1835,	702	268	$80 36
1836,	702	437	122 31¼
1837,	800	215	101 62½
1838,	811	316	76 77½

Yours, TUNIS G. BERGEN.

Improved Expanding Cultivator.

[Fig. No. 18.]



The above is a figure of an improvement on the Cultivator, invented by Jason Smith, Esq. It can be contracted or expanded at pleasure, without stopping the horse, (which is very convenient where the rows are not marked out regular,) by turning the handle A, which is connected by a half inch rod, with a cast iron cog wheel, four inches in diameter, which works in two slides screwed to the slats. The depth can be regulated by raising or lowering the beam B; a mortice is made through the hind end of the centre piece, of sufficient length to receive the wheel and both slats; the side pieces are fastened at the forward end by strong hinges. Yours respectfully. [No patent.] J. S.

Tyre, Seneca county, Jan. 3, 1839.

Dressing Hogs.

Schenectady, 2d April, 1839.

Dear Sir—The following method of dressing large hogs may be useful to your readers; if you think so, publish it. After the hogs are laid on the lumber sleigh, or whatever else is used to dress them on, they are dusted over with finely powdered rosin, from a dredging box; then they are covered with horse blankets, and hot water sufficient to wet them thoroughly, is sprinkled on them with a watering pot. In a short time they will be scalded so that the hair will come off easily, and they will be cleaned as well as in the usual way of scalding in a cask. I received this information from Mr. John Clark, who told me he once had a hog which weighed more than six hundred pounds, dressed in first rate style by this method. Also from Mr. James Rosa, who a few years since, saw in Boston, Mass. several large hogs completely dressed, in the same manner. These are two of our most respectable farmers.

Last year, Mr. Clark raised some sugar beets, and found them so useful in fattening his hogs, that this summer he intends to raise a large supply for the same purpose. Respectfully yours,

CHARLES H. TOMLINSON.

EXTRACTS.

Address, by J. J. Viele, Esq.

Delivered before the N. Y. State Agricultural Society, February 6, 1839.—(*Concluded.*)

I feel as though I am occupying too much of the time of this society, but I cannot conclude this address without again urging the importance of having some system adopted for the diffusion of science, and the improvement of the intellectual character of our yeomanry.—Here, after all that is said on this subject, lies the great secret of improvement in agriculture. Disguise it as we may, there is a lamentable deficiency of knowledge in our agricultural community. We might as well expect a bountiful and luxuriant harvest from a neglected and half cultivated field, as to expect that our system of farming will make rapid progress in improvement, without in the first instance improving the mind. Why is it that we have schools for the professions, the advantages of which are enjoyed by the few, richly endowed by the state, and have none for the many who are engaged in the pursuits of agriculture? Why is it that science is allowed to shed her radiant beams upon every other occupation but that of tilling the soil? It cannot certainly be because she requires not her aid. Every different soil requires a different treatment, and almost every different plant requires different cultivation, different applications, and different ingredients in the soil.

> "Nor every plant on every soil will grow;
> The sallow loves the wat'ry ground and low;
> The marshes alders: Nature seems t' ordain
> The rocky cliff for the wild ash's reign;
> The baleful yew to northern blasts assigns,
> To shores the myrtles, and to mounts the vines."

Every operation of the farmer is a scientific experiment, and unless he understands some of the principles, and is able to reason from cause to effect, he is wholly unable to judge whether he labors for profit or loss.—Without science, he knows as little of the principles which govern the economy of his operations, as does the ox who draws the plough, or the horse who propels machinery. Educate him, then, for his occupation, enlighten and improve his mind, and rest assured that the improvement of the soil will follow. If the science of a Buel, can ameliorate and bring into a high state of cultivation and productiveness, the pine barrens of Albany, and that of a Colman, the worn out, sterile soils of Massachusetts, might we not expect that by its general diffusion, the whole state would soon be devoid of waste places, and with almost the art of magic, be converted into a blooming garden, teeming with fruits and flowers, and the golden harvests of plenty? Will not our state, then, adopt some liberal views on this subject? With a commendable spirit, it has endowed colleges and academies in almost every city and village in the state, but it is well known that comparatively few of the sons of our farmers find their way thither, and if perchance they do, it is for the purpose of preparing themselves for some other pursuit. It is equally obvious that the course of instruction pursued in our colleges is not well adapted to shed light upon rural labor. Let us then have a school, or schools, whose object shall be to qualify young men for the pursuit of agriculture. Let there be an experimenting farm attached, with workshops, where science can be directly applied to the useful arts. There chemistry would direct them in the amelioration and improvement of soils, in the economy and right application of manures, what soils are adapted to particular crops, and whether, to renovate, he should apply compost, lime, gypsum, marl, clay or sand. By mathematics, they would learn the science of computing by numbers, which would enable them to weigh and measure all articles, whether solids or fluids. By mechanics, they would become acquainted with the structure and use of tools, the principles of machinery, and the manner in which the moving power is applied. Botany would teach them the physiology of vegetation, the nature and uses of plants, their powers of generation, the alternation that should be observed for the best development of their powers, so that the the most perfect of its kind should be produced. Geology and mineralogy would inform them of what the earth is composed, and give them a knowledge, not only of its surface, but also what is contained in the strata beneath. From zoology, they would become acquainted with the natural history of domestic animals—also their character and constitutions. Entomology would point out to them the character and habits of the various insects that depredate upon crops, and often destroy the farmer's hopes. Attached might be a department for instruction in veterinary surgery. The constitution and diseases of domestic animals could then be learned, with the appropriate treatment and remedies. Millions might annually be saved to the nation, that is now lost for the want of general knowledge on this subject. In short, all the natural sciences might there be taught, their principles exemplified, and applied to every operation upon the farm and in the workshop. We have colleges, theological, law, medical and military seminaries, richly endowed by the government, furnished with extensive libraries and costly apparatus, for illustrating the sciences, with able teachers liberally supported; but poor agriculture, hitherto a discarded daughter of the state, whose industry sows the seed and gathers the harvest, on whom all depend, and to whom all look for the comforts and blessings of life, she can have no seminary for the education of her sons in the most useful of the arts. The liberality with which all the other seminaries and institutions have been endowed, does credit to the state, and why agriculture should be thus long overlooked and neglected, "is strange, passing strange."

The advantages to be derived from an institution of this kind are incalculable. Hundreds of young men would be annually emanating from its halls, locating in different parts of the state, who by their knowledge and their example, would diffuse light upon the various subjects connected with agriculture, and could not fail to have a most salutary influence upon the moral and intellectual condition of all within their reach. The results of the experiments in all the various branches of agriculture, the mechanic arts and the use of labor saving machinery, would be heralded forth from the agricultural press, thereby reducing to certainty their utility, in the minds of the community, and saving an immense expense that is now incurred in their investigation. Under such an influence, I fondly anticipate, that soon, perhaps within the life-time of the present generation, a very great change would be wrought in the condition of our agriculture. Soon the productions of the state would be doubled—soon would the moral and intellectual condition of her sons be elevated—the entire face of nature would be changed—our rich and fertile valleys would double their increase, the barren plains be covered with verdure, "the desert and solitary place made glad, and the wilderness blossom as the rose."

What a vast field is this for the exercise of fond anticipation! What a delightful view is here presented for the imagination!

> "Oh, knew he but his happiness, of men
> The happiest he; who far from public rage,
> Deep in the vale, with a choice few retir'd,
> Drinks the pure pleasures of the *rural life*."

Nor is this the dream of a visionary, or the vagary of a heated and over sanguine imagination. What is here, by some deemed wild conjecture, or vague speculation, has in Europe, even under their despotic laws, become matters of history and well established fact. Schools of this character have there been established, not only by individual effort but also by the governments. Their beneficial effects are felt and acknowledged, in their increased productions, taxable property and value of the soil.

And has not the time now arrived, when our state, with her ample resources, will aid this noble enterprise? Will she not extend her hand, open and willing, to promote this great object? If she will not be generous, I appeal to her justice; and I ask whether she can longer refuse this pittance to poor, degraded, despised agriculture? Is she, who in war nerves her arm, and sends forth her sons to battle—she who in peace supports the government—pays the taxes—builds our splendid monuments of art—excavates our canals and freights them with the fruits of her toils—who feeds all and clothes all—and supplies all with the necessaries and luxuries of life—is she, I ask, to be denied the meagre pittance of a school to educate her sons? If this be so, I turn, as my only hope, to the public spirited and benevolent individuals in our midst; and I appeal to their generosity, to know if they are willing that this noble project should fall, still-born to the ground? What an opportunity is here presented, by the founding of an institution of this character for posthumous fame—for immortality! Have we not in this great state, some patriotic and benevolent Williams, or Brown, some public spirited Girard, who by doing a great and a good act, will enrol his name upon the scroll of fame, as a benefactor of the public, and confer blessings unnumbered upon the human race?

Farmers' Luxuries.

[*From the Quarterly Journal of Agriculture.*]

It has frequently been matter of surprise to us that small farmers, from generation to generation, pass through life at the same dull pace, going over the same rugged ground, plodding the same apathetic routine, unambitious to vary and increase their innocent recreations, when every facility is within their power to vie with their wealthier brethren in the possession of so styled luxuries. We approve that excellent aphorism, "To enjoy is to obey." Our beneficent Creator has placed innumerable sources of gratification within the reach of all his creatures. His intention evidently is, that the productions of various climes should be consumed by nations "far asunder as the poles;" that Scotland should quaff the vintage of the sunny south, that shoals of her herrings should find their way in savoury heaps to the inland dwellers of wide continents, or He would never have put it into the hearts of men to construct great ships, and to steer their course over the trackless ocean by the guidance of His heavenly sun and moon and stars. If as Lord Bacon says, "Admiration is the superlative of praise," it follows that the more we enlarge our sphere of innocent and rational enjoyment, the greater the number and variety of proofs of His creative power and wisdom we collect around us, the more must our admiration be excited, and the higher ought to be our feeling of gratitude, veneration, and praise. "Use, but do not abuse the good gifts of God," appears to us to be a text worthy of the Creator and His creatures, one that is also, in this restrictive age, cruelly neglected. But to our subject of "Farmers' Luxuries."

Who ever heard of small farmers indulging in those horticultural dainties and delicacies that require the aid of frames and hotbeds to perfect their growth? Yet who would point out a legitimate objection to an enjoyment so entirely innocuous? Why should cucumbers, (in frames of course, we mean) grapes, peaches, melons, and even pine-apples, be reserved for the gratification of patrician palates, any more than that the bloom of delicate tinted flowers should be kept sacred for the solace of the eyesight of the wealthy; or that their grateful odour should refresh exclusively the olfactory nerves of the aristocracy? Employment is the bliss of life: there is not a more unhappy being than the man or woman who is not obliged to exert those mental and bodily functions which have been beneficiently bestowed upon us, to be used for the preservation of our health; nor can there exist a more sickly, silly, pretty sounding, pernicious, little southern phrase than "*Dolce far niente.*" "*Amaro far niente*" would be nearer the truth. Luxuries that may be attained, without unjustifiably employing time and capital, are not only perfectly admissible at the tables of those who can afford them, but the man is to be applauded who seeks to secure them. The extra delicacies which we obtain by our manual dexterity and industry we are fully entitled to enjoy.

A man, however his time may appear to be entirely occupied by his business (we speak not, it is obvious, of our unhappy brethren in squalid lanes and dismal manufactories), say that of a farmer, for example, has always many hours in a week entirely unemployed, which are lolled, or dozed, or smoked, or drunk away, unless he have a love of literature strong upon him. A very few of these wasted hours might be turned to great advantage by devoting them to the cultivation of *luxuries;* and not only luxuries for self-gratification but for the sale of them, whereby many little enjoyments of other kinds might be easily attainable.

Farmers who cultivate their own land possess advantages for the accomplishment of the plan we advocate beyond those who rent their farms, who are bound by the terms of their leases from using the manure for any other purpose than the benefit of the land under tillage. In some parts of the southern portion of our island, we have been informed that the occupant is restricted from the privilege of manuring his garden with any portion of it. This is as arbitrary as it is absurd, since it is an admitted fact that manure is in a better condition for farming crops *after it has undergone that first stage of fermentation, which is precisely the state in which it would effect the desired end in obtaining "farmers' luxuries."* An outlay of a very few pounds in the first instance, would ensure a valuable return, without any increase or renewal of expense for many years. Melon-pits, peach-pits, &c., have a fearful sound; a poor man would as soon think of a service of plate for his table as of such costly and exclusively patrician erections in his garden; but we hope to prove to our farming friends, especially such of them as are industrious themselves, and have one or more sons at home to assist in the labours of the farm, that the erection of a melon-frame, peach-pit,* &c. with their cost and management, is to be as easily and cheaply obtained as any other portion of his stock.

If a man have a mechanical turn, as it is styled, (and how desirable, how valuable, is a talent for carpentering and bricklaying in all situations where the income requires strict attention to meet the demands of a family!) many, many pounds may be annually saved by exerting that talent. We have seen this exemplified in an industrious family, in which the results have been most satisfactory. *Practical* plans are those which we advocate and advise; with vague schemes we would not puzzle ourselves or our readers. The stagnant state of our agricultural brethren is beginning to interest the lords of the soil, and associations are forming to better their condition, by teaching them many elementary principles of subjects on which they are profoundly ignorant. May these institutions prosper! In the mean time, let us, in our humble way urge upon every farming man these simple truths—that active employment is a privilege, a boon bestowed upon the working classes as a compensation for the want of that wealth which the poor erroneously covet through ignorance of its attendant miseries; that industry brings contentment, that blissful feeling which wealth can never bestow; that the fiat which has been called "the curse of the ground," namely, "Thou shalt earn thy bread by the sweat of thy brow," is one of the kindest and wisest of the Creator's commands; that he who best knows how to exert the mental and bodily powers which have been given him for his benefit, is a wise and enviable man; that "knowledge is power," and not only power, but happiness. Hence no one should sit down in the supine consciousness of being a farmer, and merely a farmer, to plough, and sow, and reap and jog to market, and count his gains, and take his pipe and glass, and so to bed the whole year round, and "seek to know no more." As we have said already, there are many hours, nay, whole days, when the routine of a farm moves sluggishly, nay, when it must stand still; these are the opportunities that have been beneficently ordained, and which a mind of energy will gladly employ, in order to better his own condition, and, by the influence of example, that of his children and dependants.

Idleness is mischief, it is seldom mere inaction; and no stronger proof of the truth of this axiom need be adduced than the evident improvement in the morals of our artisans in the thickly populated towns, since the introduction of Mechanics' Institutions. Those hours which they formerly passed in *idleness*, in beer and gin shops, fostering a spirit of fierce discontent and disaffection, are now devoted to peaceful acquisition of science to attain wisdom as well as knowledge, to elevate their minds and to improve their condition.

Parents are little aware of the immense benefit, in every possible way, that results from encouraging industrious habits in their children. Very young lads may be made of essential use in a homestead, and at the same time their enjoyments would be to themselves delightful amusements. A boy who evinces the slightest turn, for mechanics, should always be indulged in his partiality and be encouraged to try his skill. A chest of rough and simple tools might be given as a reward, and opportunities afforded, should his father be unable to instruct him, for the acquirement of the right handling of his hammer and plane. Once set afloat, his own enthusiasm will carry him forward, and his parents will reap the double recompense of adding to their slender income by his pleasant exertions, and of seeing the effects of industrious habits upon his mental and bodily health, which, but for their judicious fosterage, might have been laid waste by idleness with all its train of evils.

Sheep Husbandry.

BREEDING—THE GENERATIVE AND URINARY SYSTEMS.

[*From the Library of Useful Knowledge, Farmers' Series.*]

The object of the sheep-master is to raise and to retain that animal which will pay best for the consumption of its food. With the breeder of cattle, this is a very simple affair—he selects and cultivates that animal which will attain the greatest maturity and weight in the shortest time, and on the least quantity of food. The dairyman wishes to add another quality to the aptitude to fatten, namely, the yielding, and for a considerable time, a large quantity of milk. The sheep-breeder also derives his profit from two sources, the early maturity of the carcass, and the quantity and useful properties of the wool. Both will occupy his attention; the first, in every case, and as his grand object; the second, as valuable, but regarded more as a subsidiary.—How shall he attain his objects? He looks carefully over his flock, and he observes that some of his sheep—the food and general management being the same—fatten more quickly than others. There is the same attention paid to all, but the profit is abundantly more from some than from the majority of their companions. He is anxious to account for this. He compares these sheep with some of their fellows, and he observes that there is an evident difference of conformation, a fineness of bone, a roundness and compactness of form, a condensation of substance, and a beautiful proportion of every part.—He studies this, and he finds that there is more or less of this conformation in every sheep that materially outstrips his fellows. He inquires farther, and if he has employed different rams, the one that possesses most perfectly this peculiarity of form, and its accompanying aptitude to fatten, was the parent of these promising sheep, or their dam had these points in considerable perfection. He now begins to form some notion of the kind of animal that the profitable sheep should be; and he has living proof that these valuable properties may and will descend to the offspring.

His pride and his interest are involved, and he examines these flowers of his flock with still closer attention. He finds that, in the handling, they present as great a difference to the feeling as they do to the eye. There is a softness, a springy elastic softness, in distinction from the hard, harsh, unyielding nature of the skin, and the texture immediately beneath it in others, which once impressed on the mind, can never be forgotten; and he associates this with the certainty of early maturity.

Having satisfied himself with regard to these things, he dismisses the ram that does not exhibit these qualities, or that fails in getting lambs possessing them; and the ewes that do not approach to the beau-ideal which he has formed in his own mind, or whose lambs are inferior in appearance or in thriftiness. He fattens these and sends them to the butcher. He collects together the lambs as soon as their form and qualities begin to develop themselves—a little experience will enable him to judge accurately of this at a very early age—and without hesitation he discards those that are not up to the mark, whether ram or ewe-lambs. He puts by a few of the very best of the males for a second examination at no very distant time, and every faulty one is selected from the ewe-lambs, and prepared for the butcher as quickly as may be. In this way the flock is systematically and rapidly improved, and the breeder is well repaid for the diligent attention which he has given to this important object. *If his flock is large, he will find in this principle of selection, every thing that he can want.*

There is one point more, the importance of which he cannot overrate—*he should never preserve a lamb that has an evident and glaring defect.* In proportion as his flock improves, he should regard this as a rule that admits of no exception; for the principle that "like produces like" extends as powerfully to the defects as to the excellencies of the animal. The progeny infallibly inherits the defects as well as the excellencies of the parent, and no improvement in a good point, already possessed to a considerable extent, can compensate for the introduction of an obvious blemish.

On this principle of selection, the breeder will continue to proceed, if his flock is tolerably large, and he will even be jealous of the introduction of a foreign breed. The good qualities of his sheep, transmitted from one generation to another, are no longer accidental circumstances. They have become a part and portion of the breed, and may be calculated upon with the greatest degree of certainty. They constitute the practical illustration of the term *blood*. It would be long ere the good qualities of a stranger would form an identical portion of the sheep; and no animals will elsewhere thrive so well, or improve so rapidly, as on the pastures on which they and their forefathers have, generation after generation, been accustomed to wander.

---

* Our farmers want neither melon-frames nor peach-pits. These fruits generally ripen well in the open ground of our genial soil and climate. The farmers luxuries which a bountiful Providence has placed within their reach, *and for their use,* are the fruits and culinary vegetables, which our climate will mature, and which add as well to the health as to the innocent enjoyments of life—the apple, the pear, the plum, the grape, &c of the best varieties—the beet the onion, the melon, the tomato, the rhubarb, the asparagus, &c. which are the desire of the rich, which the grower alone can enjoy in perfection—and which, we are sorry to say, very few of our farmers do duly appreciate or enjoy. And the ornamental department, which may tend much to improve our minds, and to enlarge the sphere of our innocent enjoyments, is almost wholly neglected, as though the Giver of all Good had prohibited the use, to the tillers of the soil, of what he has placed within their reach, and impliedly for their special benefit.—*Cond. Cult.*

But, after a while, with a considerable degree of certainty in a small flock, and too frequently in a larger one, the sheep will continue to arrive early at maturity, and to fatten as kindly as before, or even more so, but they evidently are decreasing a little, and yet only a little, in size. They do not bear the severity of the weather quite so well, and perhaps they are somewhat more subject to disease. The farmer will do well to take warning. He has been breeding too long from close affinities; and he must introduce a little different and yet congenial blood. He must select a ram from a soil, and kind of food, not dissimilar to his own, although at a distance perhaps as great as convenience will permit—with points as much resembling his own sheep as may be—quite as good as those in his own flock—superior if possible in some points, and inferior in none, and he must dismiss his own ram for one year, and make use of the stranger. His purpose will be completely answered. He will have infused a tone and vigor among his sheep—they keep their propensity to fatten, and they re-acquire that health and hardiness which they used to exhibit, and the farmer is enabled to go on satisfactorily for a certain number of years; when experience will tell him that a stimulus, in the form of a little foreign blood, is again wanted. Thus is illustrated that axiom with regard to all our domesticated animals—"selection with judicious and cautious admixture, is the true secret of forming and improving a breed." The errors to be avoided are, too long continued and obstinate adherence to one breed; and, on the other hand, and even more dangerous, violent crosses, in which there is little similarity between the soil, the pasture or the points and qualities of the animals that are brought together.*

The ewe is sufficiently matured for breeding at fifteen or eighteen months. The old farmers did not employ them for this purpose, until after the second shearing; but the improvement in the breed, which develops so soon a disposition to fatten, and prepares them so much earlier for the market, hastens also the development of the generative powers in the sheep.

The ewes and rams being kept in different pastures, the farmer can select his own time for bringing them together, and consequently, the time for yeaning; and that will depend on various circumstances. Where there is a demand for house-lambs, or the farmer adopts the rearing of such lambs as a part of his system of management, the period of yeaning should commence as early as September or October, in order that in November and December the lambs may be ready for the market, and, at which time they will obtain a good remunerating price.

In the general course of breeding, however, it is desirable that the lambs should not fall until the cold of winter is over, and the pasture begins to afford some food for the little ones. This is peculiarly important in bleak and exposed situations. Thousands of lambs die every year from the cold to which they are exposed as soon as they are yeaned. On the other hand, there may be some inconvenience and danger if the period of lambing is too late. Hot weather is as fatal to the mother as cold is to the offspring. It frequently induces a dangerous state of fever; and both the mother and the lamb may be then injured by the luxuriance of the grass. If the lamb falls late in the season, it will be longer ere the ewe can be got ready for the butcher, and the ground cleared for other stock—and, in addition to this, the early lambs become larger and stronger and better able to resist the cold of the succeeding winter. The yeaning time will, therefore, be regulated by the situation of the farm, the nature of the pasture, and the demand from the neighboring markets. It will seldom, however, commence before the middle of March, or be postponed beyond the middle of April.

The duration of pregnancy is about five months, or 152 days, and that with comparatively trifling deviation.† The time for putting the ram with the ewes will therefore be from the middle of October, to that of November. No preparation is necessary, except, for a few weeks previously, to place the ewes on somewhat better pasture than usual. Before the ram is admitted, the farmer should always fold and examine the ewes, first as to their possessing that form and appearance that are likely to perpetuate the breed which he is desirous to possess, and secondly, to ascertain whether they are in good health, the proof of which will be the whiteness and firmness of their teeth, the sweetness of their breath—the brightness of the eye and of the countenance, the degreee of fat which they carry, and the firmness with which the wool adheres to the pelt. Every inferior or diseased ewe should be separated from the rest, and prepared, as speedily as may be, for the butcher.

In consequence of the new system of breeding and management, the ram will be sufficiently matured at the same age as the ewe; but it will not, perhaps, be prudent to allow him so many ewes as would be placed with one of greater age. The number should be somewhat regulated by the apparent health and strength of the animal, and the pasture from which he comes.—Forty or fifty ewes may be allowed to the sheerling, and seventy or eighty to the older ram.

Native Stock vs. Durham.

[*From the Yankee Farmer.*]

Mr. Editor—I observed in the Farmer of Jan. 5, an article upon the superior value of the Durham breed of cattle. It is there stated that a farmer can afford to give five hundred dollars for a full blood Durham bull, and the calculation is carried out to show how quickly, easily and certainly he will get his pay back.

I affirm that we have no need to go abroad for stock for our farms. The only secret is in managing well the stock that we have. Take the best Durham breed, or any other that can be produced, and let our farmers treat them as they have heretofore treated our native cattle, hogs and sheep, and in a few generations they will be as poor and mean. The whole art in having good stock of any kind, is to select, from year to year, the best for breeders.

The present goodness of our native stock, considering how it has been uniformly treated from year to year, by the owner, is ample proof of its real goodness. The only thing wanted is constant and proper selection and proper keeping, and our stock would soon be equal to any. As long as our farmers will continue to sell off cows that are worth one hundred dollars and keep those that are hardly worth five, we may never expect to see a fine breed of cattle. The farmers may import what breed they please, and pay as high prices as they please, it will be all the same thing in the end, until they learn to manage better. The rules for selecting for good stock are principally these—deep wide shoulders, wide and deep hips, short and straight back bones, round bodies and well ribbed back, short shin bones, short strong necks, small short heads, and small pointed noses. If these rules were observed from generation to generation, by our farmers, the meanest breed of cattle that were ever seen would soon become first rate. Just so with your hogs and sheep. A very large creature, of any kind, is not so profitable to the farmer, as a good, middling size. The main thing is shape. And no farmer should ever sell at any price, his best and finest shaped animals, if he intends to keep up a good and profitable kind. A gentleman told me lately that he began farming about twenty years ago. He then took a good deal of pains to find and purchase a superior kind of sheep. He could find none on an average better than his own, which were mean. He adopted the practice of selecting his best lambs every year, for stock. In a few years he had the first rate sheep. The same course will produce the same effects in every kind of animal.

Instead of paying five hundred dollars for a Durham bull, let any farmer lay out that sum in extra keeping and care of his present stock, and select his best calves every year for stock, at the end of five years he will be better off. I do not deny the notion of purchasing a superior quality of stock, when it can be done, at a fair reasonable price, but only the notion of running into such great extravagance of prices. A little care and patience will serve our farmers a much better purpose, and, in the end give them full as good and profitable a stock. PHILO.

Portland, January 8, 1839.

Animal Nutrition.

[*From the Genesee Farmer*]

Until within a very few years, little attention seems to have been paid to the subject of animal nutrition; the quantity or kind of food most suitable for this purpose was mostly overlooked, and if life was supported, no questions were asked as to the why and the wherefore. So long as the population of the old world remained few in number compared with the acres from which subsistence was to be drawn, there was indeed little use in inquiries of this kind; then, as now in the United States, or this continent generally, a supply of food of some kind was usually certain. Now and then years of famine in particular sections might occur;—for in those times, when the means of intercourse were so limited, the inhabitants of one country might be starving, while those at a distance of a few hundred miles were rioting in abundance; but they were soon forgotten in the succeeding plenty, and led to no valuable investigations as to the nature of food or nutrition. The population fared more nearly alike in former times than at present, so far as food was concerned; it was bulky and hearty, and if it produced disease, it was of a different kind from that which now assails the modern omniverous eater and drinker, and in all cases was decidedly the same. In these days, the differences in mankind made by rank or wealth, are scarcely more deeply marked than those observable between the diseases of the rich and the poor; a difference in the main to be attributed to the nature of their diet, and its effects on the animal system.

Among the inquiries into the effect of different kinds of food or animal nutrition, Dr. Stark, of Vienna, appears to have taken the lead; indeed he seems to have fallen a marter to his zeal in the cause of science, perishing, as he undoubtedly did, from the results of his long continued experiments on *himself*. By confining himself to food of a particular kind for a considerable space of time, he was able to ascertain its actual effect on the organs of digestion, and its value as a source of nourishment. Bread, meat and milk, each in its turn, for a considerable period, was his sole nutriment; and the result showed that these things, certainly among the most nutritive of substances, could not maintain the vigor of the body, or even life itself, but for a limited time. In this respect man differs from the majority of animals; his organization is such as to admit and even require a variety of food, while many animals are by a law of their natures confined to a particular kind of food, as flesh or vegetables.

The French physiologists, Magendie and his coadjutors, followed up the experiments of Stark, not on themselves, but on animals, and found they could not long survive on food, however nutritious in itself, unless they receive a large portion of that on which they naturally subsist. Thus a dog fed on white sugar and water alone, soon became emaciated, lost its appetite and sight and perished. Few substances can be more nutritive than sugar, but it lacked the power of properly distending the stomach, and exciting its digestive energies.—Dogs fed on pure wheat bread and water lived but little longer; and rabbits, which eat a variety of vegetables, such as clover, cabbage, barley, corn and carrots, were unable to live for any time confined to one of these. It was found that animals, when much emaciated and reduced by one kind of food, were not often restored by another, though they frequently partook of it with greediness—the tone of the stomach could not be regained.

To facilitate proper digestion of food by the animal or man, it is necessary that with the nutritive part, substances more bulky, or containing little nutritive power, should at the same time be taken as food. An experiment has been made in England on the feeding of horses, which demonstrates this fact most conclusively.—Some cavalry horses were selected, and while one part of them received sugar and water alone, the other part had a few pounds of cut straw added to their portion of sugar and drink. Those which received the sugar alone fell away rapidly, while those fed with the sugar and straw throve as perceptibly; and a repetition of the experiment on another set of animals, showed the same result. In man the rich and high seasoned food, the fine flour and the fat meat, are to the stomach what pure wheat or sugar would be to the stomach of the horse. There is much nutriment, but little that can facilitate digestion. A man swallows nourishment enough for half a dozen, but instead of its producing a good effect, his stomach becomes disordered, its functions debilitated, and in the midst of plenty he becomes dyspeptic, and incapable of enjoying any thing. The man who lives on common food, sound and sufficiently nutritious, is rarely troubled with the evils that press so heavily on him who, regardless of the law of nature, takes more nutriment and less substance than is consistent with a healthy tone of the digestive powers.

Perhaps the best estimate of the time required for the digestion of the various substances used as food by man, and their general effect on the animal organization, is given in the book of Dr. Beaumont, from experiments made on the living subject, and under circumstances more favorable to correctness than are known to have ever before existed. We give below a table of the results obtained by him, not as a mere matter of curiosity, but as furnishing information of the most valuable kind in connection with animal nutrition. The first column indicates the substances taken into the stomach; the last the time required for its digestion.

	hour.	min.
Boiled rice,.........................	1	00
Sago, tapioca, barley and boiled milk,..	2	15
Tripe and pigs' feet,.................	1	00
Fowls, beef's liver,..................	2	30
Hard eggs,............................	3	30
Soft eggs,............................	3	00
Custard,..............................	2	45

Cabbage boiled,.......................	4	30

Dr. Beaumont found that the envelop of the seeds in the apple and the skins of potatoes were scarcely acted upon by the gastric juice, and consequently indigestible. As a whole, it would seem that animal aliments are digested easier than vegetable ones; but his experiments show conclusively, that whatever the kind of food, the ultimate principle of nutrition, or the chyle, is the same in all cases.

Digestion is much facilitated by the particles of food being made fine when taken into the stomach, and the quantity of nutritive matter furnished is greater. Individuals, therefore, in whom the digestive powers are weakened, find a benefit in thoroughly masticating or chewing their food. This principle is of great importance in the feeding or fattening of animals, and shows the necessity of grinding or cooking the materials given them, if we are anxious they should derive the full benefit of the nutritive matter contained in them.

---

* See Quarterly Journal of Agriculture, Sept. 1836, p. 250. Low's Elements of Agriculture, p. 492, and Dickson's Practical Agriculture, vol. ii. p. 639.

† M. Tessier presented a valuable memoir to the Royal Academy of Science in Paris, containing his observations on the period of pregnancy of almost every domestic animal — Out of 912 ewes, the shortest period was 146 days, and the longest 161, being a difference of 15 days; but more than three parts of them yeaned between the 150th and 154th day after impregnation; bringing the average as nearly as possible to 152 days, or five calendar months, or twenty-one weeks and five days

The experiments of Dr. Beaumont further proved, that when food of great nutritive powers was taken into the stomach in large quantities, the functions of that organ were evidently clogged, and that usually, in eating, a larger quantity of nutritive matter was received than was beneficial. A certain quantity of solid food, or food of a bulky nature, he found to be essential to digestion with ease, and a proper separation of the nutritive principle. This agrees with the fact, that horses or cattle require cut straw or hay mixed with their grain, both to ensure mastication, and furnish the necessary bulk of solid matter in the stomach. It is a common saying with farmers, that an ox, when feeding on meal, must be furnished with a lock of hay to make him a cud. They require more than this, and the reason, from what has been said above, is perfectly obvious.

Capabilities of Soils—Vegetable Physiology.

[*From Prof. Jackson's 2d Annual Report of the Geology of the Public Lands of Maine and Massachusetts.*]

It is evident that plants are not endowed with creative powers, and consequently are unable to produce any new elementary substances; hence the various substances which enter into their composition, must be derived from the air, water or earth. All the saline and earthy matters which they contain, are readily traced to their origin in the soil; while the carbon, hydrogen, oxygen, and nitrogen that exist in them, are elements which they draw from air, water, and the animal and vegetable substances used as manures.

The atmosphere is composed chiefly of the two gases, nitrogen and oxygen, mixed together in aeriform solution, in the proportion of four-fifths nitrogen and one-fifth oxygen; besides which gases there is always a certain proportion of carbonic acid gas, amounting to $\frac{1}{10,000}$ part, and variable proportions of aqueous vapor.

From the carbonic acid gas of the atmosphere, plants derive a large share of their carbon, which is the basis of all vegetable matter. Some of it is also furnished by the fermentation of vegetable and animal substances, which decompose in the soil, and this gas is either decomposed by the leaves of vegetables, or is carried into their roots by aqueous solution and absorption. All fresh growing plants decompose the carbonic acid of the air, take up its carbon, and exhale oxygen gas, and this operation goes on more rapidly while the sun shines upon them. In darkness, plants give out carbonic acid, but the quantity is relatively small, when compared with that which they absorb during the day. So that if a plant is grown under a bell glass, containing air mixed with this gas, the carbonic acid is soon removed, and replaced by pure oxygen.

Thus vegetation is continually removing a substance deleterious to man and all animals, and replacing it by pure vital air—a gas absolutely necessary for their respiration. This beautiful law of nature should never be lost sight of by the farmer, nor should he ever forget the relation which the green woods and fields bear to the healthfulness of the country.

Seed will not germinate without the joint action of air, water, light* and heat. Without these essential conditions, the germ remains, as it were. asleep for an unknown length of time. Seeds taken from the tombs of ancient Thebes, in Egypt, where they had remained in a dry, dark and sequestered spot, for more than three thousand years, were found still to possess their vital properties, and when planted in a botanical garden in London, sprang forth to flourish in the present age.—How long a seed, thus immured in darkness, shut out from all the causes which would produce germination or decay, would remain alive, is wholly unknown; but from the known facts respecting spontaneous rotation of crops and of forest trees, it would seem that the seeds remain buried in the soil for enormous lengths of time, before the circumstances necessary for their putting forth arrive. Dead leaves of the forest shut out light, and preclude, in some measure, the influence of the atmosphere, while the sombre foliage hangs over the soil, and serves, by its shade, as an additional cause of preventing germination. Thus, I suppose, the seed, buried in the forests, remain dormant until the removal of the shade trees, or the burning of the leaves, gives free access to the causes requisite for germination and growth of the hidden plants; and we consequently perceive a new growth almost invariably follows the removal of the primeval forests. According to Decandole, plants exude from their rootlets certain substances, which have the property of eventually eradicating their own species, while they are not preventive of the growth of other plants; hence he accounts for natural rotation.† It is probable, also, that one kind of vegetables may exhaust their proper nutriment, and thus render the soil incapable of supporting their kind, while there are other principles left suitable for the support of different species. This subject is, however, the most obscure department of vegetable physiology, and one which demands the labor of modern chemists and botanists.—Thus much we know, that the conditions above stated are essential requisites to healthy vegetation, and that the soil must furnish certain substances not attainable alone from air and water. When we analyze a plant, we always find a certain quantity of silex, alumina, lime and potash, forming a large proportion of the ashes which is left on burning the plant. All these matters are contained in the soil, in greater or less proportions, and some of them are essential to the growth of the plants. The coating of wheat, rye and barley straw is silex, and gives the necessary strength and hardness to the stalk.

The analysis of the grain of wheat gives a large proportion of the carbonate and phosphate of lime, and we know that this grain only thrives upon a soil containing calcareous matter. It was long ago observed in Massachusetts, and is also seen in certain districts in Maine, that wheat straw grows very well, but the grain does not fill and present a plump and solid appearance, but looks wilted, and is not heavy. This was formerly supposed to be owing to the climate, but on more careful examination, it is found to arise from the want of lime in the soil. Many animal manures contain a little of this substance. and it accordingly appears, that where a farm is well manured, wheat will grow well upon it, but a large annual expenditure is required for the purpose. It is observed, that all the grain regions of the country have soils more or less calcareous, and we find, that, by adding lime to the soil, we may produce by art the material wanting; and it appears by analyses made in this country, and by the results of certain experiments which have been made in France, and repeated here, that a very minute proportion of lime is amply sufficient for the purpose. Thus one or two per cent of carbonate of lime will answer the purpose, and this small quantity costs so little, that any farmer can well afford to apply it to the soil. Indeed, I do not see how he can afford to do otherwise, since he will be a loser, and his more skilful neighbors will be enabled to supply the market, while he will not be able to recover his seed.

It is a great mistake to suppose, that wheat will grow in any soil; for I know that in many instances, the crop raised the past season, which has certainly been very propitious, did not equal in value the seed sown; and these instances all occurred where the soil was destitute of lime, and was not largely manured.

Unless you wish to waste your labor upon barren and unproductive fields, attend carefully to the nature of your soil, and supply those elements which are wanting, in order to render it fruitful.

When lime is moistened with water, it becomes hot, swells, and falls into a bulky white powder, called by chemists the hydrate of lime, it being composed of water combined with that substance in a solid state.—This powder, if the lime is of good quality, will amount to nearly three times as much as before it was slaked, so that one cask of lime will fill three casks with the hydrate, or water-slaked lime. If, on the other hand, the lime is exposed to the action of the air, it will attract carbonic acid gas, and become air-slaked, which operation re-converts it into its original chemical state. The hydrate also attracts carbonic acid from the air, and is likewise converted into the carbonate, which will weigh nearly twice as much as the quick-lime, from which it is made.

I mention these evident facts, in order to assure the farmer, that when he buys a cask of lime, it will make about three of the article which he uses as a manure, and consequently, that it is not so expensive as he might imagine, since it increases in bulk, and will cover a considerable surface. Moreover, by a skilful management the farmer may, by the use of lime, form a vast number of valuable composts, and may destroy, or not, as he pleases, the seeds and insects in his compost or barn manure. It also has the power of decomposing animal and vegetable substances, the extent of which operations, a skilful hand can regulate at will, and a great variety of valuable saline compounds, the most active of manures, may be formed. There are many cases, also, where the combining power of this substance can be taken advantage of, in the neutralization or removal of deleterious matters, and, by judicious management, those very principles may be converted into valuable manures.

It is a common practice among farmers, to make use of peat, pond mud, or muck, as they call it, and I have observed instances in which it was evident that the soil was greatly injured by its application. In one instance I observed, in Waterford, that a portion of the field on which this substance was placed, presented a dwarfish and sickly yellow crop of Indian corn, while that part of the field not treated by it, was covered with a most luxuriant and healthy growth of the same corn. The operation was tried experimentally, in order to ascertain the value of peat alone as manure.

If it had first been made into a compost, with animal manure and lime, it would have presented very different results. Lime alone on peat renders its acid properties inert, and then it answers pretty well as a manure. But if laid down in layers with barn-yard manure, night soil, dead fish, or any other animal matter, and then each layer strewed with lime, a most powerful fermentation will take place, and a vast quantity of ammonia will be disengaged, which combining with the ulmic acid of peat, will form ulmate of ammonia, a most powerful manure. Carbonate of ammonia, and many other salts, will also result, which convert the whole mass into the very richest kind of manure, forming what may be properly called a universal compost.

If the farmer is desirous of destroying the seeds and insects in barn-yard manure, let him heap it up in alternate layers, with fresh quick-lime, and the heat generated will effectually destroy them.* This operation produces a number of soluble salts, and therefore it should only be done where the manure is soon to be used, for the rain would remove them in solution.

If a soil is charged with sulphate of iron, it is best to use quick-lime in powder, sprinkled on the surface of the soil, for its action is the more rapid and powerful. Generally, however, it is proper to slake the lime with water, and then to expose it freely to the air, in case it is to be sown broad-cast, so that it may become carbonated, which renders it more permanent, it being less soluble in water.

In general, it may be stated, that about four casks of lime are required for each acre of land, and according to the experience of M. Puvis, this quantity, in many cases, was found amply sufficient. If the soil is loose and sandy, without any clay bottom near the surface, it is evident that annual renewals will be required, until the desirable quantity is obtained.

Marl may be used in the same manner as air-slaked lime, and it is found to possess similar properties. Sea-shells may be used when broken to pieces by the action of fire, or by frost, and great benefit is gained by such a dressing. Shells owe their fertilizing properties to the carbonate of lime, of which they are chiefly composed, but their compact texture requires to be broken down in the manner alluded to.

Burnt bones contain a small quantity of carbonate, mixed with a large proportion of the phosphate of lime, and may be advantageously used. Bones ground to powder, have also a very powerful and desirable influence, forming one of the most valuable top-dressings with which we are acquainted. The refuse bone black, from sugar refineries, is also extremely powerful, and is one of the warmest and strongest manures known. It is highly prized in France, and I have formerly mentioned the fact, that orders were even sent to this country for this article. It may be made into a compost with other matters, since it is too strong to be used alone.

Gypsum is said to operate well as a stimulant to vegetation, and acts powerfully where the soils are calcareous. In Pennsylvania, it is is sown broad-cast upon their limestone soils, and operates powerfully, favoring the growth of grain and grasses. In Maine, it is the general opinion of farmers, that this mineral does not succeed upon the sea-coast, while it answers a good purpose in the interior of the state. I am not yet prepared, however, to report upon the subject, since I have not been able to gather the requisite number of facts.

How should Manure be applied?

[*From the Yankee Farmer.*]

Mr. Editor—One of your correspondents has criticised with something of severity on a recommendation of the agricultural committee of Massachusetts to spread compost manure and harrow it in. On what ground Philo calls this an old error, we cannot easily imagine. Having read with some attention treatises on agriculture for nearly forty years, we remember no period when the question has not been in discussion and dispute among theorists, whether manure should be left near the surface, or buried deep under the soil. There has been the manifestations of great zeal and some asperity on the subject. The advocates of surface manuring have generally preferred the charge against their opponents for manurig the antipodes, and they themselves have been as confidently accused of manuring the atmosphere. Each theory has the support of some very respectable names, and the opposition of others of equal weight. Observation and experience should determine the course of the practical farmer. We hope very many will make fair experiments on the recommendations of the committee, notwithstanding what has been written in opposition to it; for we believe after repeated trials, that it is the most perfect cultivation ever practised in this country. Did Philo attend critically to the whole recommendation? Does it not as a whole, approach nearer to a part of his own theory than he has supposed? It is recommended, first to turn the soil carefully over, to such depth as may be indicated by the character of the land, and the plants we propose to place in it. The turf we turn under is never to be disturbed in the subsequent culture. Now we have at the foundation of the soil, such a fermenting mass as your correspondent desires, not perhaps so powerful, but as certain and enduring. A practical objection against turning under all the manure we apply to the land with the turf, is, there will not be action and energy enough in what we make surface soil in ploughing to produce a crop. We want the quick operation of manure that takes place near the surface. We think there may be philosophical objections of great weight against burying manure deep in the earth; we claim not the ability of discussing fully such objections, but beg leave to call the attention of Philo to some remarks of Dr. Jackson, which will at least convince him that all scientific men cannot assent to his doctrines.

"The loss of the saline matters of manures, by solution and infiltration," the Doctor remarks, "is vastly greater than is commonly supposed by farmers. The evaporation, to which so much loss is attributed, is but a drop in the bucket, in comparison with that of solution. Some maintain that manures never penetrate the earth beyond the depth of a few inches; but this is a great error. The most important ingredient, viz: the soluble salts, penetrate the earth to an enormous depth, and we find animal matters in the well waters of Boston, one hundred and fifty feet below the surface. I know also of instances where deep well water, formerly free from saline and animal matter, became charged with them two years after the top soil had been cultivated and dressed with animal manures. Hence it is evident, that since all the fresh water of our wells infiltrates from the top soil, that the soluble salts, whether of animal, vegetable or mineral nature, will be dissolved and carried down by the action of water, and they are as I know, easily detected in the water at great depths. Hence the value of a clay substratum in our fields, where the soils are porous, and the facts coincide with the theory, as I have frequently had occasion to observe."

---

* We think *light* not necessary, but prejudicial, in the process of germination.—*Cond.*

† This theory of Decandolle is not tenable.—*Cond.*

* Of very doubtful utility.—*Cond.*

Philo speaks of the philosophy of nature in the fermentation and decomposition of manures; why should not practical men take rules for the application of manure from indications in nature? All the provision that is made in the order of Providence in the decay and consumption of one crop for the nourishment of another—all the droppings of animals and the defoliation of plants and trees, lodge on the surface of the earth. The order established in nature seems to contradict the idea of any immense loss in evaporation.—Apply manure in any manner, no doubt there will be some loss in it. If, in deep burying, we endeavor to retain the ascending gases to the latest possible period, we shall not at any time have enough of their influences to produce the most vigorous vegetation. If we leave the manure on or near the surface, some of it may grow inert by drying, or blow into neighboring fields; still it is only when placed near the surface, that the most direct and greatest effects are produced on plants.

OBSERVATOR.

"On Burying Manure Deep."

We were much gratified in reading the communication of Philo, in your last number, and have long been a believer in his philosophy of manure. On this subject, we have heretofore briefly given our views, and we ask your indulgence at this time, to permit us to say a word more, "in hopes it may be instrumental in producing some good, although compared with the famous contributions of our friend Ben Barleycorn, it may be thought of no great import." It must be obvious to all who till the soil, that even the salts or earthy particles of manure do not sink deep into the earth,—we have abundant evidence of this in the appearance of the soil, even where fields have been heavily manured. At a certain depth, the soil will exhibit its natural colour and texture, and give no indication, by its effects on crops, of having been impregnated with the solutions of animal or vegetable matter. The philosophy of this is, the earth acts as a strainer, and, as Philo says, "this is a wise provision of nature—that the most impure water is made pure by filtration through a few inches of light soil."

It is a fact well understood, that the gases generated by manure, whilst undergoing fermentation, always ascend, because they are lighter than atmospheric air, and unless the manure is buried sufficiently deep, they escape and are lost, or become a fruitful source of disease."

The influence of the sun and atmosphere have a tendency to prevent even the salts or earthy matter from sinking deep into the soil—the fibrous roots of every tribe of the vegetable kingdom are always on the alert, and are attracted to the depositories of their natural aliment, with the precision of the needle to the pole.

In this our own experience compels us to dissent from some of the views of the learned geologist of Maine, in his valuable communications to the agricultural commission of Massachusetts. [See quotation in the preceding article.]

Now it seems to us a more reasonable thing to believe, that the animal matter detected in wells of that depth, [150 feet,] was driven by the wind through the crevices in the platform, or the waters impregnated with these salts immediately round the well, found their way by some subterraneous passage, through the stoning near the surface. Were his theory correct, we should be very unwilling to take up our abode among some of the intelligent farmers near the city, who are in the habit of dressing their land very liberally with night soil, undivested of its noxious effluvia, by the Frenchman's process of converting it into poudrette. For our own comfort, we hope at least the doctor is mistaken; for all the water we make use of is drawn from a well located in our barn-yard; this well has supplied us with water for fifteen years, and we have never been able to detect any saline or soluble salts in it, but occasionally we detect *animal matter* in the shape of *rats*, which find their way there in the same manner that we imagine all *animal matter* must find its way into a well 150 feet deep. With the exception named we were highly gratified with the perusal of the doctor's communication; it contains a fund of valuable information that should be familiar to every farmer. We are, however, strong in the faith, that farmers in general lose ten times the manure by evaporation, that they do by infiltration.—And we think as a general rule, manure judiciously buried with the plough, is as secure to the farmer for future crops, as is his money when placed in the vaults of a solvent bank.

Mattakees, April, 1839.

Culture of Indian Corn.

[*From the Genesee Farmer.*]

GREAT YIELD.

Mr. Tucker—As the time of year is near at hand, for planting *corn*, I propose giving you for publication, my experience in raising corn, and more particularly my success for the last year. I will first say that I think, in this vicinity, farmers have been in the habit of planting too much ground, or in other words, more than they have well tilled and manured. I had lost my whole crop, or nearly so, for two or three years previous to the last season, except some small patches, and in my garden. I have sometimes planted on ground of clay and muck, that would hold the water so long in the spring that the corn would get backward, and thereby get overtaken with the frost, while a little more than fit to roast. Two years ago I sent to the Rochester Seed Store and got a small quantity of the early Dutton corn. I planted about one-fourth of an acre, which gave me more sound corn than I had on three acres adjoining—same quality of land—but taking the whole together, it was still a losing business. I then resolved to take a different course, first, to plant on a different soil; second, to plant no more than I could make as rich as my garden. My garden is of a gravelly, dry soil, of course rich. In it I had every year planted some corn; sometimes near the first of April, and at other times quite late, but ever have failed to get good corn even in our poorest seasons. Adjoining the garden, the natural soil is the same, and I came to the conclusion that I could take some of it and make it produce as well as my garden. Therefore, last season I planted about an acre with the early Dutton, or Buel corn, and the result was one hundred and twelve bushels of shelled corn to the acre. This is a great yield for this country, and in fact is beyond any thing I have ever before seen. There was more sound corn than I had raised for a number of years before. The season was a favorable one, and aside from that I attribute my success to three things, viz: manuring high, planting thick, and a prolific kind of seed corn. The tilling was nothing but ordinary. In the fall of 1837, the ground was in timothy and clover, with a light sward, having been stocked about two years. I then ploughed it late in the fall. In the spring following I covered it over with common coarse manure from the barn-yard, which was composed of a large quantity of straw. My stock is principally sheep, and straw was thrown into the yard plentifully during the winter for bedding. In drawing it out a load was usually dropped in a place, so that after it was spread, it completely covered the ground to quite a thickness. About the middle of May the ground was ploughed very deep, and boys were sent ahead of the plough and raked all the manure into the previous furrow, so that it was completely covered. Some of my neighbors then said that they should rather have that coarse manure off from the ground than on it, for the good of the corn crop, and said it would do no good till the next crop, or until it should be decomposed. I will here remark, that from reason and experience, I must protest against leaving manure in the yard over summer, or even putting it into heaps to decay as some do to heat and drain off the strength all summer. On the contrary in most cases it is most as cheap to haul it into the field, as to heap it up in the yard. We get the use of it one year sooner, and have all the strength on the land where it should be instead of being washed into the streams of water. I think for corn and potatoes, that the benefit the first year will more than pay the expense of carting ordinary distance. To return to my subject, I next harrowed and furrowed my ground, or rather marked it very shallow, three feet apart. It was now the 17th of May, having been hindered a number of days by a heavy rain. I put three kernels in a hill, and sixteen to eighteen inches apart. It being rather cold and wet, the corn did not sprout quick as usual, and on examination I found that a small wire worm that was probably in the manure, had eaten into the chit of the corn, so that only a part of it was coming up. Although now as late as the 4th of June, I commenced planting over by putting in just as much seed as I did the first time, a hill between every two hills, which made them nearly join. As I had only seed enough left of the kind, to plant over 118 rods of the ground, the rest was planted over to beans. I will here state that the 118 rods was all the ground that was manured, and a cast made on an acre from that ratio. The rest was equally as good corn, but the ground not well stocked. When I hoed the first time, I concluded at the second hoeing to pull out some where it was the thickest, but I left them for some time, and forgot to tell my man to do it; therefore it all stood. I told him to hoe it twice more, but he did not hoe it but once, having for an excuse that the corn got so large, he could not, making only two hoeings. The stalks were 8 or 10 feet high, and a complete swamp to appearance.

Now some of my neighbors said it would be all stalks and no corn. On the night of the 2d of September, I think we had a severe frost which killed the stalks, but the corn was all ripe, the last planted as well as the first; making for the last planted just 13 weeks. It needed no sorting to grind, and handsomer corn I never saw. As to its being all stalks and no corn, the result showed. I am strong of the opinion that great improvements can be made in planting by distributing the seed more over the ground and by putting in more of it.

I fear I have wearied your patience about a small field of corn, and will close by saying that if any of the above is worth publishing you can do it, if not, throw it under the table.

L. C.

Darien, Genesee Co., April 19th, 1839.

The new mode of drawing.

It would appear from the following Report of the proceedings of the London Royal Society, at one of their sittings in February, which we copy from the London Literary Gazette, that the invention called the daguerroscope, which has been claimed by the French, is contested by Henry Fox Talbot, Esq. an Englishman.

A highly interesting paper by Henry Fox Talbot, Esq. was read. It detailed the author's discovery upwards of 5 years ago, of the new process of delineating objects.—From the first volume of the journal of the Royal Institution, it apppears that the late Mr. Wedgewood had some idea of the discovery. That ingenious gentleman in conjunction with Sir H. Davy, made many experiments, but they found all their endeavors to obtain success ineffectual, so much so that it discouraged them, and would have discouraged the author of the present memoir, had he not read the remarks of Sir H. Davy, contained in the journal alluded to, prior to the experiments which ultimately led to his invention. At first it consisted of laying the nitrate of silver on paper, and by means of the camera obscura and the solar ray acting on the paper, a perfect impression is obtained of any object in half a second; it was found, however, that the image thus obtained, by exposure to the light, faded, and after a while disappeared. By repeated experiments and the most devoted attention, Mr. Talbot, by what he calls sensitive paper (a great improvement upon that which he originally employed,) has overcome this great drawback; pictures he has had in his possession for years, are now as vivid as they were when first produced. The image obtained is white, but the ground is beautifully colored, and readily obtainable, either sky-blue, yellow, rose-color, or black; green is excluded; these variations of color, Mr. Talbot considers as so many chemical compounds. Objects the most minute are obtained—the delicate hairs on the leaves of plants, the most minute and tiny bivalve calyx, nay, even a shadow, the emblem of all that is most fleeting in this world, is fettered by the spell of the invention, and remains perfect and permanent long after it has been given back to the sunbeam which produced it; in short, to use Mr. Talbot's own words, the picture is "ended as soon as begun." The extent of the value of this invention cannot at present be anticipated; already the author has applied it with perfect success to the copying of sculpture, engravings, handwritings; and in every case so complete has been the image, that it has been mistaken for the original. The value of it even now to naturalists and others travelling abroad, many of whom are ignorant of drawing, must be immense. Lord Brougham was present, and paid profound attention to Mr. Talbot's paper.

An Act respecting School District Libraries.

Passed April 15, 1839.

The People of the State of New-York, represented in Senate and Assembly, do enact as follows:

§ 1. The trustees of every school district shall be trustees of the library of such district, and the property of all books therein, and of the case and other appurtenances thereof, shall be deemed to be vested in such trustees, so as to enable them to maintain any action in relation to the same. It shall be their duty to preserve such books and keep them in repair; and the expenses incurred for that purpose may be included in any tax list to be made out by them as trustees of a district, and added to any tax voted by a district meeting, and shall be collected and paid over in the same manner. The librarian of any district library shall be subject to the directions of the trustees thereof, in all matters relating to the preservation of the books and the appurtenances of the library, and may be removed from office by them for wilful disobedience of such directions, or for any wilful neglect of duty; and whenever they shall have reason to apprehend the loss of any such books, or their injury, or destruction by his misconduct, and whenever a vacancy shall exist in the office of librarian, the same shall be supplied by the trustees until the next annual meeting of the inhabitants of the district.

§ 2. Trustees of school districts shall be liable to their successors for any neglect or omission, in relation to the care and superintendence of district or joint libraries, by which any books therein are lost or injured, to the full amount of such loss or injury, in an action on the case, to be brought by such successors in their name of office.

§ 3. A set of general regulations respecting the preservation of school district libraries, the delivery of them by librarians and trustees to their successors in office, the use of them by the inhabitants of the district, the number of volumes to be taken by any one person at any one time or during any term, the periods of their return, the fines and penalties that may be imposed by the trustees of such libraries for not returning, losing or destroying any of the books therein, or for soiling, defacing or injuring them, may be framed by the superintendent of common schools, and printed copies thereof shall be furnished to each school district of the state, which regulations shall be obligatory upon all persons and officers having charge of such libraries, or using or possessing any of the books thereof. Such fines may be recovered in an action of debt, in the name of the trustees of any such library, of the person on whom they are imposed, except such person be a minor; in which case they may be recovered of the parent or guardian of such minor, unless notice in writing shall be given by such parent or guardian to the trustees of such library, that they will not be responsible for any books delivered such minor. And persons with whom minors reside shall be liable in the same manner, and to the same extent, in cases where the parent of such minor does not reside in the district.

§ 4. Any person conceiving himself aggrieved by any act or decision of any trustees of school districts concerning district school libraries or the books therein, or the use of such books, or of any librarian, or of any district meeting in relation to the school library, may appeal to the superintendent of common schools, in the same manner as provided by law in relation to common schools, and his decisions thereon shall be final.

§ 5. The legal voters in any two or more adjoining districts may in such cases as shall be approved by the superintendent of common schools, unite their library moneys and funds as they shall be received or collected, and purchase a joint library for the use of the inhabitants of such districts, which shall be selected by the trustees thereof, or by such person as they shall designate, and shall be under the charge of a librarian to be appointed by them; and the foregoing provisions of this act shall be applicable to the said joint libraries, except that the property in them shall be deemed to be vested in all the trustees for the time being of the districts so united. And in case any such district shall desire to divide such library, such division shall be made by the trustees of the two districts whose libraries are so united: and in case they cannot agree, then such division shall be made by three disinterested persons, to be appointed by the superintendent of common schools.

§ 6. The moneys directed to be distributed to common schools by the fourth section of chapter two hundred and thirty-seven of the acts of 1838, shall be applied to the purchase of books for a district library for the term of five years; and the said moneys shall be distributed to the school district in the same manner and proportions as the public school money, and upon the like terms and conditions in all respects. And if by reason of non-compliance with such conditions, any library money shall be withheld, from any school district, the same may be distributed among other districts complying with such conditions, or may be retained and paid subsequently to the district from which the same was withheld, as shall be directed by the superintendent of common schools, according to the circumstances of the case.

§ 7. The superintendent of common schools, whenever requested by the trustees of a school district under the directions of the legal voters of such district, may select a library for their use, and cause the same to be delivered to the clerk of the county in which such district is situated, at its expense. He shall transmit a sufficient number of copies of this act, to supply each school district in the state, with forms and instructions for its execution, to the clerks of the respective counties, who shall forward the number directed to each school district in his county to the clerk thereof.

State of New-York, Secretary's Office.—This act having been approved and signed by the governor on the 15th day of April, 1839, I do hereby certify that the same became a law on that day.

JOHN C. SPENCER, *Secretary of State.*

Insectivorous Birds.

[*From the New-England Farmer.*]

Mr. Fessenden.—These are to the farmer and gardener of great value. They were designed by the Creator to check the too great increase of insects; and no farmer ought to suffer them to be wantonly destroyed on his premises. The number of insects destroyed by the robin, swallow, sparrow, mock-bird, and other small birds, is astonishing. One little family will destroy several hundreds in a single day. Some little time since, a pair of these small birds built a nest on a lilac, which grew close to one of my windows. In the time of incubation, there was a long and severe storm and a strong wind. The eggs were in danger of being thrown overboard by the writhing of the bush. Conscious of this, the female kept on the nest to prevent any accident which might follow on her leaving it, to collect food. Her mate, like a good provider, was busily engaged through the day in collecting food (insects) which he carried to his companion, and she received it of him with apparent affection. This circumstance excited particular attention; and of course this little society was closely observed. In a short time the eggs hatched; but from the roughness of the weather, or tenderness of the brood, the female chose not to leave the young. During this time, the male with surprising industry, brought small insects, in the larva state, to the nest, but was not suffered to feed the nestlings. The female received the food, and divided it among her little charge. When the young gained sufficient strength, the male was permitted to feed them; and from this time, both parents were mutually and incessantly, (by day) employed in collecting small insects from every quarter; and, on a moderate calculation, to the number of about 700 in a day.

One great cause of the increase of many insects, so destructive to vegetation is the decrease of those little friends to the agriculturist. Should a few of them innocently trespass on the property of the farmer to the amount of a few cents, let him remember, that he is greatly indebted to them for services rendered; and not wage a war of extermination.

They are not merely useful in destroying insects—for they call the farmer and the gardener to their business—cause the groves to resound with music, and usher in the morning with melodious praise.

R. GREEN.

Mansfield, March 27, 1838.

Cure for Hydrophobia.

[*From the Liverpool Mercury, July* 2.]

As the hydrophobia season has set in, we comply with the request of a correspondent, by giving insertion to the following. What we happen to know of the extraordinary property of the chloride of lime induces us to put great faith in its properties in the cure of the wound inflicted by dogs, or any other means.

We are indebted to M. Coster, a French physician, for the following valuable discovery, as a preventive to hydrophobia. Take two table spoonfuls of fresh chloride of lime in powder, mix it with half a pint of water, and with this wash keep the wound constantly bathed, and frequently renewed. The chlorine gas possesses the power of decomposing this tremendous poison, and renders mild and harmless that venom against whose resistless attack the artillery of medical science has been so long directed in vain. It is necessary to add that this wash should be applied as soon as possible after the infliction of the bite. Another plan which has been extensively tried at Breslau and Zurich, and many other parts of the continent, consists not merely in cutting out the bitten part, (mere incision has been found too often unavailing,) but in combining with the incision some effectual means for keeping open the wound and maintaining it in a state of suppuration during a period of at least six weeks. Other curative means, as the exhibition of mercury, balladonna or lyetoe, were also employed in the cases; but upon these, it is thought, little reliance can be placed. The following are the results of this treatment:—From 1810 to 1824, the number of persons admitted into the Breslau, was 184, of whom two only died of hydrophobia; from 1783 to 1824 inclusive, there were admitted into the hospital at Zurich 233 persons, bitten by different animals, (182 by dogs,) of whom only four died—two on the second day of admission, and in whom the disease had probably become developed before they were submitted to the treatment, and the other two were bitten in parts (inside of the cheek and eyelid,) where the prescribed means could not be employed with the requisite exactness.

Literary Statistics.

[*From the American Almanac.*]

The number of new works which appeared in the United States, in 1834 and 1835, amounted to 1,013, forming 1,300 volumes, and the cost of which may be estimated at $1,220,000. In 1836, the number was considerably increased, and the cost of the books published in that year cannot be computed at less than $1,500,000. Boston, New-York, Philadelphia and Hartford, furnished 19-20ths of the total amount.

Another statement for the years 1833, 1834 and 1835, is as follows:—Originals 1,030, reprints 854; total 1,884;—number of volumes printed, (1,000 for each edition,) 1,884,000.

In most cases the editions of one and the same work are larger and more frequent in the United States than in any other country. Many reprinted English works have here passed through three or four editions, while the publishers of the original in England have but one. In one instance, the sale of a book in America amounted to 100,000 copies, whereas in England only four editions of 1,000 copies each, were disposed of.

The amount of literary productions in America has more than doubled during the last ten years. The sale of five bookselling establishments amounted, in 1836, to $1,350,000. A single publisher paid, in the five years preceding 1834, $135,000 for copyrights, out of which $30,000 were for two works only. Carey, Lea & Blanchard paid last year $30,000 to American writers; and Harper & Brothers have paid about the same sum for several years past.

The following statement will show the relative proportion of native and imported literary productions, in 1834:

	Native.	*Imported.*
Education, ...	73	9
Divinity, ...	37	18
Novels and Tales, ...	19	95
History and Biography, ...	19	17
Jurisprudence, ...	20	3
Poetry, ...	8	3
Travels, ...	8	10
Fine Arts, ...	8	0
Miscellaneous Works, ...	59	43

Thus it appears in American literature the scientific and practically useful predominate, and that works of imagination are chiefly derived from foreign sources. The school-books are almost all written or compiled in the United States; and some idea of the extensive business done in them may be formed from the circumstance, that, of some of the most popular compilations in geography, from 100,000 to 300,000 copies have been sold in ten years; so that, in many instances, works of this kind produce a permanent income, as well to the author as the publisher. During the last five years, the number of American orignal works, in proportion to reprints, has nearly doubled.

The Pickman Farm.

The famous Pickman farm, in Salem, the best in the county, is lined round the borders of the fields, with engrafted apple trees. These trees are very thrifty, deriving most of their nourishment from the ground under the walls, which keep the soil loose, warm and moist, and preserve the roots of the trees from external injury. The trees in this situation are an ornament to the farm, while they are no hindrance to the farmer in cultivating his field, nor injury to the crops, by withdrawing nourishment, like those in the interior of the field. Yet those trees round the field are believed to yield a greater profit than the annual crop within, with all the labor necessarily bestowed upon it—and the annual sales of the apples and fruit on this farm are said to be enough to purchase a farm of moderate dimensions in the interior of the state.—*Newburyport, Mass. Herald.*

New Motive Power.

The Worcestershire Chronicle says—"We have been favored by a correspondent with the following account of an invention which, if what is said of it be correct, promises to make some stir in the world.

"'Her Majesty's letters patent have been granted to Mr. Byron l'Anson Bromwick, of Clifton-on-Teme, in this country, for an improved method of propelling all kinds of machinery, both stationary and locomotive.—The power is of equal magnitude to that of steam; it can be obtained at one-sixteenth part of the cost of that power, without the incumbrance of a boiler and its ponderous and objectionable appendages;—consequently carriages constructed almost as light and elegant as those now drawn by horses, can be propelled by this power, along the common roads or rail-ways, at any speed consistent with safety. As a motive power applied to ships and boats, it will be invaluable, there being do danger from explosion, nor any annoyance from smoke, steam, or noise; and the space now devoted to the boiler, fuel, &c. will be at liberty to be more profitably employed. The invention will be submitted to the ordeal of public opinion, as soon as the patent rights for France, Belgium and Holland have been disposed of."

Young Men's Department.

Self-Culture.

BY W. E. CHANNING, D.D.

We were so highly pleased with the perusal of the following lecture upon Self-Culture, by the Rev. Dr. Channing, that we asked permission of the Executive Committee of the Franklin Lectures, Boston, to whom the copy-right belonged, to publish it in the Cultivator. Our readers will no doubt unite with us in the expression of thanks to the committee, for their cheerful compliance with our request. The lecture will occupy a portion of two or three of our numbers.

ADDRESS.

My Respected Friends—By the invitation of the committee of arrangements for the Franklin lectures, I now appear before you to offer some remarks introductory to this course. My principal inducement for so doing, is my deep interest in those of my fellow-citizens for whom these lectures are principally designed. I was informed, that they were to be attended chiefly by those, who are occupied by manual labor; and, hearing this, I did not feel myself at liberty to decline the service, to which I had been invited. I wished by compliance to express my sympathy with this large portion of my race. I wished to express my sense of obligation to these, from whose industry and skill I derive almost all the comforts of life. I wished still more to express my joy in the efforts they are making for their own improvement, and my firm faith in their success. These motives will give a particular character and bearing to some of my remarks. I shall speak occasionally as among those who live by the labor of their hands. But I shall not speak as one separated from them. I belong rightfully to the great fraternity of working-men. Happily in this community we all are born and bred to work; and this honorable mark, set on us all, should bind together the various portions of the community.

I have expressed my strong interest in the mass of the people; and this is founded, not on their usefulness to the community, so much as on what they are in themselves. Their condition is indeed obscure; but their importance is not on this account a whit the less. The multitude of men cannot from the nature of the case be distinguished; for the very idea of distinction is, that a man stands out from the multitude. They make little noise and draw little notice in their narrow spheres of action; but still they have their full proportion of personal worth and even of greatness. Indeed every man, in every condition, is great. It is only our own diseased sight which makes him little. A man is great as a man, be he where or what he may. The grandeur of his nature turns to insignificance all outward distinctions. His powers of intellect, of conscience, of love, of knowing God, of perceiving the beautiful, of acting on his own mind, on outward nature, and on his fellow-creatures, these are glorious prerogatives. Through the vulgar error of undervaluing what is common, we are apt indeed to pass these by as of little worth. But as in the outward creation, so in the soul, the common is the most precious. Science and art may invent splendid modes of illuminating the apartment of the opulent; but these are all poor and worthless, compared with the common light which the sun sends into all our windows, which he pours freely, impartially over hill and valley, which kindles daily the eastern and western sky; and so the common lights of reason, and conscience, and love are of more worth and dignity than the rare endowments which give celebrity to a few. Let us not disparage that nature which is common to all men; for no thought can measure its grandeur. It is the image of God, the image even of his infinity, for no limits can be set to its unfolding. He who possesses the divine powers of the soul is a great being, be his place what it may. You may clothe him with rags, may immure him in a dungeon, may chain him to slavish tasks. But he is still great. You may shut him out of your houses, but God opens to him heavenly mansions. He makes no show indeed in the streets of a splendid city; but a clear thought, a pure affection, a resolute act of a virtuous will, have a dignity of quite another kind and far higher than accumulations of brick, and granite, and plaster, and stucco, however cunningly put together, or though stretching far beyond our sight. Nor is this all. If we pass over this grandeur of our common nature, and turn our thoughts to that comparative greatness, which draws chief attention, and which consists in the decided superiority of the individual to the general standard of power and character, we shall find this as free and frequent a growth among the obscure and unnoticed as in more conspicuous walks of life. The truly great are to be found every where, nor is it easy to say, in what condition they spring up most plentifully. Real greatness has nothing to do with a man's sphere. It does not lie in the magnitude of his outward agency, in the extent of the effects which he produces. The greatest men may do comparatively little abroad. Perhaps the greatest in our city at this moment are buried in obscurity. Grandeur of character lies wholly in force of soul, that is, in the force of thought, moral principle and love, and this may be found in the humblest condition of life. A man brought up to an obscure trade, and hemmed in by the wants of a growing family, may, in his narrow sphere, perceive more clearly, discriminate more keenly, weigh evidence more wisely, seize on the right means more decisively, and have more presence of mind in difficulty, than another who has accumulated vast stores of knowledge by laborious study; and he has more of intellectual greatness. Many a man, who has gone but a few miles from home, understands human nature better, detects motives and weighs character more sagaciously, than another, who has travelled over the known world, and made a name by his reports of different countries. It is the force of thought which measures intellectual, and so it is force of principle which measures moral greatness, that highest of human endowments, that brightest manifestation of the Divinity. The greatest man is he who chooses the right with invincible resolution, who resists the sorest temptations from within and without, who bears the heaviest burdens cheerfully, who is calmest in storms and most fearless under menace and frowns, whose reliance on truth, on virtue, on God is most unfaltering; and is this a greatness, which is apt to make a show, or which is most likely to abound in conspicuous station? The solemn conflicts of reason with passion—the victories of moral and religious principle over urgent and almost irresistible solicitations to self-indulgence—the hardest sacrifices of duty, those of deep-seated affection and of the heart's fondest hopes—the consolations, hopes, joys, and peace of disappointed, persecuted, scorned, deserted virtue; these are of course unseen; so that the true greatness of human life is almost wholly out of sight. Perhaps in our presence, the most heroic deed on earth is done in some silent spirit, the loftiest purpose cherished, the most generous sacrifice made, and we do not suspect it. I believe this greatness to be most common among the multitude, whose names are never heard. Among common people will be found more of hardship borne manfully, more of unvarnished truth, more of religious trust, more of that generosity which gives what the giver needs himself, and more of a wise estimate of life and death, than among the more prosperous.—And even in regard to influence over other beings, which is thought the peculiar prerogative of distinguished station, I believe, that the difference between the conspicuous and the obscure does not amount to much. Influence is to be measured, not by the extent of surface it covers, but by its *kind*. A man may spread his mind, his feelings and opinions through a great extent; but if his mind be a low one, he manifests no greatness. A wretched artist may fill a city with daubs, and by a false showy style achieve a reputation; but the man of genius, who leaves behind him one grand picture, in which immortal beauty is embodied, and which is silently to spread a true taste in his art, exerts an incomparably higher influence.—Now the noblest influence on earth is that exerted on character; and he, who puts forth this, does a great work, no matter how narrow or obscure his sphere. The father and mother of an unnoticed family, who, in their seclusion, awaken the mind of one child to the idea and love of perfect goodness, who awaken in him a strength of will to repel all temptation, and who send him out prepared to profit by the conflicts of life, surpass in influence a Napoleon breaking the world to his sway. And not only is their work higher in kind; who knows but that they are doing a greater work even as to extent or surface than the conqueror? Who knows, but that the being, whom they inspire with holy and disinterested principles, may communicate himself to others; and that by a spreading agency, of which they were the silent origin, improvements may spread through a nation, through the world? In these remarks you will see why I feel and express a deep interest in the obscure, in the mass of men. The distinctions of society vanish before the light of these truths. I attach myself to the multitude, not because they are voters and have political power, but because they are men, and have within their reach the most glorious prizes of humanity.

In this country, the mass of the people are distinguished by possessing means of improvement, of self-culture, possessed no where else. To incite them to the use of these, is to render them the best service they can receive. Accordingly I have chosen for the subject of this lecture, *Self-culture*, or the care which every man owes to himself, to the unfolding and perfecting of his nature. I consider this topic as particularly appropriate to the introduction of a course of lectures, in consequence of a common disposition to regard these and other like means of instruction, as able of themselves to carry forward the hearer. Lectures have their use.—They stir up many, who, but for such outward appeals, might have slumbered to the end of life. But let it be remembered, that little is to be gained simply by coming to this place once a week, and giving up the mind for an hour to be wrought upon by a teacher. Unless we are roused to act upon ourselves, unless we engage in the work of self-improvement, unless we purpose strenuously to form and elevate our own minds, unless what we hear is made a part of ourselves by conscientious reflection, very little permanent good is received.

Self-culture, I am aware, is a topic too extensive for a single discourse, and I shall be able to present but a few views which seem to me most important. My aim will be, to give first the idea of self-culture, next its means, and then to consider some objections to the leading views which I am now to lay before you.

Before entering on the discussion, let me offer one remark. Self-culture is something possible. It is not a dream. It has foundations in our nature. Without this conviction, the speaker will but declaim, and the hearer listen without profit. There are two powers of the human soul which make self-culture possible, the self-searching and the self-forming power. We have first the faculty of turning the mind on itself; of recalling its past, and watching its present operations; of learning its various capacities and susceptibilities, what it can do and bear, what it can enjoy and suffer; and of thus learning in general what our nature is, and what it was made for. It is worthy of observation, that we are able to discern not only what we already are, but what we may become, to see in ourselves germs and promises of a growth to which no bounds can be set, to dart beyond what we have actually gained to the idea of perfection as the end of our being. It is by this self-comprehending power that we are distinguished from the brutes, which give no signs of looking into themselves. Without this there could be no self-culture, for we should not know the work to be done; and one reason why self-culture is so little proposed is, that so few penetrate into their own nature. To most men, their own spirits are shadowy, unreal, compared with what is outward. When they happen to cast a glance inward, they see there only a dark, vague chaos. They distinguish, perhaps, some violent passion, which had driven them to injurious excess, but their highest powers hardly attract a thought; and thus multitudes live and die as truly strangers to themselves, as to countries, of which they have heard the name, but which human foot has never trodden.

But self-culture is possible, not only because we can enter into and search ourselves. We have a still nobler power, that of acting on, determining and forming ourselves. This is a fearful as well as glorious endowment, for it is the ground of human responsibility.—We have the power not only of tracing our powers, but of guiding and impelling them, not only of watching our passions, but of controlling them, not only of seeing our faculties grow, but of applying to them means and influences to aid their growth. We can stay or change the current of thought. We can concentrate the intellect on objects which we wish to comprehend.—We can fix our eyes on perfection and make almost every thing speed us towards it. This is indeed a noble prerogative of our nature. Possessing this, it matters little what or where we are now, for we can conquer a better lot, and even be happier for starting from the lowest point. Of all the discoveries which men need to make, the most important at the present moment, is that of the self-forming power treasured up in themselves. They little suspect its extent, as little as the savage apprehends the energy which the mind is created to exert on the material world. It transcends in importance all our power over outward nature. There is more of divinity in it, than in the force which impels the outward universe; and yet how little we comprehend it! How it slumbers in most men unsuspected, unused! This makes self-culture possible, and binds it on us as a solemn duty.

I. I am first to unfold the idea of self-culture; and this, in its most general form, may easily be seized. To cultivate any thing, be it a plant, an animal, a mind, is to make grow. Growth, expansion is the end. Nothing admits culture, but that which has a principle of life, capable of being expanded. He, therefore, who does what he can to unfold all his powers and capacities, especially his nobler ones, so as to become a well proportioned, vigorous, excellent, happy being, practises self-culture.

This culture of course has various branches corresponding to the different capacities of human nature; but though various, they are intimately united and make progress together. The soul, which our philosophy divides into various capacities, is still one essence, one life; and it exerts at the same moment, and blends in the same act its various energies of thought, feeling and volition. Accordingly, in a wise self-culture, all the principles of our nature grow at once by joint harmonious action, just as all parts of the plant are unfolded together. When therefore you hear of different branches of self-improvement, you will not think of them as distinct processes going on independently on each other, and requiring each its own separate means: Still a distinct consideration of these is needed to a full comprehension of the subject, and these I shall proceed to unfold.

First, self-culture is Moral, a branch of singular importance. When a man looks into himself he discovers two distinct orders or kinds of principles, which it behooves him especially to comprehend. He discovers desires, appetites, passions which terminate in himself, which crave and seek his own interest, gratification, distinction; and he discovers another principle, an antagonist to these, which is impartial, disinterested, universal, enjoining on him a regard to the rights and happiness of other beings, and laying on him obligations which *must* be discharged, cost what they may, or however they may clash with his particular pleasure or gain. No man, however narrowed to his own interest, however hardened by selfishness, can deny, that there springs up within him a great idea in opposition to interest, the idea of duty, that an inward voice calls him more or less distinctly to revere and exercise impartial justice, and universal good will. This disinterested principle in human nature we call sometimes reason, sometimes conscience, sometimes the moral sense or faculty. But, be its name what it may, it is a real principle in each of us, and it is the supreme power within us, to be cultivated above all others, for on its culture the right development of all others depends. The passions indeed may be stronger than the conscience, may lift up a louder voice; but their clamour differs wholly from the tone of command in which the conscience speaks.—They are not clothed with its authority, its binding power. In their very triumphs they are rebuked by the moral principle, and often cower before its still, deep, menacing voice. No part of self-knowledge is more important, than to discern clearly these two great principles, the self-seeking and the disinterested; and the most important part of self-culture is to depress the former, and to exalt the latter, or to enthrone the sense of duty within us. There are no limits to the growth of this moral force in man, if he will cherish it faithfully. There have been men, whom no power in the universe could turn from the right, by whom death in its most dreadful forms has been less dreaded, than transgression of the inward law of universal justice and love.

In the next place, self-culture is Religious. When we look into ourselves we discover powers, which link us with this outward, visible, finite, ever changing world. We have sight and other senses to discern, and limbs and various faculties to secure and appropriate the material creation. And we have too a power, which cannot stop at what we see and handle, at what exists within the bounds of space and time, which seeks for the infinite, uncreated cause, which cannot rest till it ascend to the eternal, all-comprehending mind. This we call the religious principle, and its grandeur cannot be exaggerated by human language; for it marks out a being destined for higher communion than with the visible universe. To develop this, is eminently to educate ourselves. The true idea of God, unfolded clearly and livingly within us, and moving us to adore and obey him, and to aspire after likeness to him, is the noblest growth in human, and I may add, in celestial natures. The religious principle, and the moral, are intimately connected, and grow together. The former is indeed the perfection and highest manifestation of the latter. They are both disinterested. It is the essence of true religion to recognise and adore in God the attributes of impartial justice and universal love, and to hear him commanding us in the conscience to become what we adore.

Again. Self-culture is Intellectual. We cannot look into ourselves without discovering the intellectual principle, the power which thinks, reasons, and judges, the power of seeking and acquiring truth This indeed we are in no danger of overlooking. The intellect being the great instrument by which men compass their wishes, it draws more attention than any of our other powers. When we speak to men of improving themselves, the first thought which occurs to them is, that they must cultivate the understanding, and get knowledge and skill. By education, men mean almost exclusively intellectual training. For this, schools and colleges are instituted, and to this the moral and religious discipline of the young is sacrificed. Now I reverence, as much as any man, the intellect; but let us never exalt it above the moral principle. With this it is most intimately connected. In this its culture is founded, and to exalt this is its highest aim. Whoever desires that his intellect may grow up to soundness, to healthy vigour, must begin with moral discipline. Reading and study are not enough to perfect the power of thought. One thing above all is needful, and that is, the disinterestedness which is the very soul of virtue. To gain truth, which is the great object of the understanding, I must seek it disinterestedly. Here is the first and grand condition of intellectual progress. I must choose to receive the truth, no matter how it bears on myself. I must follow it, no matter where it leads, what interests it opposes, to what persecution or loss it lays me open, from what party it severs me, or to what party it allies. Without this fairness of mind, which is only another phrase for disinterested love of truth, great native powers of understanding are perverted and lead astray; genius runs wild; "the light within us becomes darkness." The subtlest reasoners, for want of this, cheat themselves as well as others, and become entangled in the web of their own sophistry. It is a fact well known in the history of science and philosophy, that men, gifted by nature with singular intelligence, have broached the grossest errors, and even sought to undermine the grand primitive truths on which human virtue, dignity and hope depend. And on the other hand, I have known instances of men of naturally moderate powers of mind, who by a disinterested love of truth and their fellow creatures, have gradually risen to no small force and enlargement of thought. Some of the most useful teachers in the pulpit and in schools, have owed their power of enlightening others not so much to any natural superiority, as to the simplicity, impartiality and disinterestedness of their minds, to their readiness to live and die for the truth. A man who rises above himself, looks from an eminence on nature and providence, on society and life. Thought expands as by a natural elasticity, when the pressure of selfishness is removed. The moral and religious principles of the soul, generously cultivated, fertilize the intellect. Duty, faithfully performed, opens the mind to truth, both being of one family, alike immutable, universal and everlasting.

I have enlarged on this subject, because the connexion between moral and intellectual culture is often overlooked, and because the former is often sacrificed to the latter. The exaltation of talent as it is called, above virtue and religion, is the curse of the age. Education is now chiefly a stimulus to learning, and thus men acquire power without the principles which alone make it a good. Talent is worshipped; but, if divorced from rectitude, it will prove more of a demon than a god.

Intellectual culture consists, not chiefly, as many are apt to think, in accumulating information, though this is important, but in building up a force of thought which may be turned at will on any subjects, on which we are called to pass judgment. This force is manifested in the concentration of the attention, in accurate penetrating observation, in reducing complex subjects to their elements, in diving beneath the effect to the cause, in detecting the more subtle differences and resemblances of things, in reading the future in the present, and especially in rising from particular facts to general laws or universal truths. This last exertion of the intellect, its rising to broad views and great principles, constitutes what is called the philosophical mind, and is especially worthy of culture. What it means, your own observation must have taught you. You must have taken note of two classes of men, the one always employed on details, on particular facts, and the other using these facts, as foundations of higher, wider truths. The latter are philosophers. For example, men had for ages seen pieces of wood, stones, metals falling to the ground. Newton seized on these particular facts, and rose to the idea, that all matter tends, or is attracted, towards all matter, and then defined the law according to which this attraction or force acts at different distances, thus giving us a grand principle which, we have reason to think, extends to and controls the whole outward creation. One man reads a history and can tell its events, and there stops. Another combines these events, brings them under one view, and learns the great causes which are at work on this or another nation, and what are its great tendencies whether to freedom or despotism, to one or another form of civilization. So one man talks continually about the particular actions of this or another neighbor; whilst another looks beyond the acts to the inward principle from which they spring, and gathers from them larger views of human nature. In a word, one man sees all things apart and in fragments, whilst another strives to discover the harmony, connexion, unity of all. One of the great evils of society is, that men occupied perpetually with petty details, want general truths, want broad and fixed principles. Hence many, not wicked, are unstable, habitually inconsistent, as if they were overgrown children rather than men. To build up that strength of mind, which apprehends and cleaves to great universal truths, is the highest intellectual self-culture; and here I wish you to observe how entirely this culture agrees with that of the moral and the religious principles of our nature, of which I have previously spoken. In each of these, the improvement of the soul consists in raising it above what is narrow, particular, individual, selfish, to the universal and unconfined. To improve a man, is to liberalize, enlarge him in thought, feeling and purpose. Narrowness of intellect and heart, this is the degradation from which all culture aims to rescue the human being.

Again. Self-culture is Social, or one of its great offices is to unfold and purify the affections, which spring up instinctively in the human breast, which bind together husband and wife, parent and child, brother and sister; which bind a man to friends and neighbors, to his country, and to the suffering who fall under his eye, wherever they belong. The culture of these is an important part of our work, and it consists in converting them from instincts into principles, from natural into spiritual attachments, in giving them a rational, moral, and holy character. For example, our affection for our children is at first instinctive; and if it continue such, it rises little above the brute's attachment to its young. But when a parent infuses into his natural love for his offspring moral and religious principle, when he comes to regard his child as an intelligent, spiritual, immortal being, and honors him as such, and desires first of all to make him disinterested, noble, a worthy child of God and the friend of his race, then the instinct rises into a generous and holy sentiment. It resembles God's paternal love for his spiritual family. A like purity and dignity we must aim to give to all our affections.

Again. Self-culture is practical, or it proposes as one of its chief ends to fit us for action, to make us efficient in whatever we undertake, to train us to firmness of purpose and to fruitfulness of resource in common life, and especially in emergencies, in times of difficulty, danger and trial. But passing over this and other topics for which I have no time, I shall confine myself to two branches of self-culture which have been almost wholly overlooked in the education of the people, and which ought not to be so slighted.

In looking at our nature, we discover, among its admirable endowments, the sense or perception of Beauty. We see the germ of this in every human being, and there is no power which admits greater cultivation; and why should it not be cherished in all? It deserves remark, that the provision for this principle is infinite in the universe. There is but a very minute portion of the creation, which we can turn into food and clothes, or gratification for the body; but the whole creation may be used to minister to the sense of beauty. Beauty is an all-pervading presence. It unfolds in the numberless flowers of the spring. It waves in the branches of the trees and the green blades of grass. It haunts the depths of the earth and sea, and gleams out in the hues of the shell and the precious stone. And not only these minute objects, but the ocean, the mountains, the clouds, the heavens, the stars, the rising and setting sun, all overflow with beauty. The universe is its temple; and those men, who are alive to it cannot lift their eyes without feeling themselves encompassed with it on every side. Now this beauty is so precious, the enjoyments it gives are so refined and pure, so congenial with our tenderest and noble feelings, and so akin to worship, that it is painful to think of the multitude of men as living in the midst of it, and living almost as blind to it, as if, instead of this fair earth and glorious sky, they were tenants of a dungeon. An infinite joy is lost to the world by the want of culture of this spiritual endowment. Suppose that I were to visit a cottage, and to see its walls lined with the choicest pictures of Raphael, and every spare nook filled with statues of the most exquisite workmanship, and that I were to learn, that neither man, woman nor child ever cast an eye at these miracles of art, how should I feel their privation; how should I want to open their eyes, and to help them to comprehend and feel the loveliness and grandeur which in vain courted their notice. But every husbandman is living in sight of the works of a diviner artist; and how much would his existence be elevated, could he see the glory which shines forth in their forms, hues, proportions and moral expression! I have spoken only of the beauty of nature, but how much of this mysterious charm is found in the elegant arts and especially in literature? The best books have most beauty. The greatest truths are wronged if not linked with beauty, and they win their way most surely and deeply into the soul when arrayed in this their natural and fit attire. Now no man receives the true culture of a man, in whom the sensibility to the beautiful is not cherished; and I know of no condition in life from which it should be excluded. Of all luxuries this is the cheapest and most at hand; and it seems to me to be most important to those conditions, where coarse labor tends to give a grossness to the mind. From the diffusion of the sense of beauty in ancient Greece, and of the taste for music in modern Germany, we learn that the people at large, may partake of refined gratifications which have hitherto been thought to be necessarily restricted to a few.

What Beauty is, is a question which the most penetrating minds have not satisfactorily answered; nor, were I able, is this the place for discussing it. But one thing I would say; the beauty of the outward creation is intimately related to the lovely, grand, interesting attributes of the soul. It is the emblem or expression of these. Matter becomes beautiful to us, when it seems to lose its material aspect, its inertness, finiteness and grossness, and by the ethereal lightness of its forms and motions, seems to approach spirit; when it images to us pure and gentle affections; when it spreads out into a vastness which is a shadow of the Infinite; or when in more awful shapes and movements it speaks of the Omnipotent. Thus outward beauty is akin to something deeper and unseen, is the reflection of spiritual attributes; and of consequence the way to see and feel it more and more keenly, is to cultivate those moral, religious, intellectual and social principles of which I have already spoken, and which are the glory of the spiritual nature; and I name this that you may see, what I am anxious to show, the harmony which subsists among all branches of human culture, or how each forwards and is aided by all.

There is another power, which each man should cultivate according to his ability, but which is very much neglected in the mass of the people, and that is the power of Utterance. A man was not made to shut up his mind in itself; but to give it voice and to exchange it for other minds. Speech is one of our grand distinctions from the brute. Our power over others lies not so much in the amount of thought within us, as in the power of bringing it out. A man of more than ordinary intellectual vigor, may for want of expression, be a cypher, without significance, in society. And not only does a man influence others, but he greatly aids his own intellect, by giving distinct and forcible utterance to his thoughts. We understand ourselves better, our conceptions grow clearer, by the very effort to make them clear to another. Our social rank too depends a good deal on our power of utterance. The principal distinction between what are called gentlemen and the vulgar lies in this, that the latter are awkward in manners, and are especially wanting in propriety, clearness, grace, and force of utterance. A man who cannot open his lips without breaking a rule of grammar, without showing in his dialect or brogue or uncouth tones his want of cultivation, or without darkening his meaning by a confused, unskilful mode of communication, cannot take the place to which perhaps his native good sense entitles him. To have intercourse with respectable people, we must speak their language. On this account, I am glad that grammar and a correct pronunciation are taught in the common schools of this city. These are not trifles; nor are they superfluous to any class of people. They give a man access to social advantages, on which his improvement very much depends. The power of utterance should be included by all in their plans of self-culture.

I have now given a few views of the culture, the improvement, which every man should propose to himself. I have all along gone on the principle, that a man has within him capacities of growth, which deserve, and will reward, intense, unrelaxing toil. I do not look on a human being as a machine, made to be kept in action by a foreign force, to accomplish an unvarying succession of motions, to do a fixed amount of work, and then to fall to pieces at death, but as a being of free spiritual powers; and I place little value on any culture, but that which aims to bring out these, and to give them perpetual impulse and expansion. I am aware, that this view is far from being universal. The common notion has been, that the mass of the people need no other culture than is necessary to fit them for their various trades; and though this error is passing away, it is far from being exploded. But the ground of a man's culture lies in his nature, not in his calling. His powers are to be unfolded on account of their inherent dignity, not their outward direction. He is to be educated, because he is a man, not because he is to make shoes, nails, or pins. A trade is plainly not the great end of his being, for his mind cannot be shut up in it; his force of thought cannot be exhausted on it. He has faculties to which it gives no action, and deep wants it cannot answer. Poems, and systems of theology and philosophy, which have made some noise in the world, have been wrought at the work-bench and amidst the toils of the field. How often, when the arms are mechanically plying a trade, does the mind, lost in reverie or day dreams, escape to the ends of the earth! How often does the pious heart of woman mingle the greatest of all thoughts, that of God, with household drudgery! Undoubtedly a man is to perfect himself in his trade, for by it he is to earn his bread and to serve the community. But bread or subsistence is not his highest good; for if it were, his lot would be harder than that of the inferior animals, for whom nature spreads a table and weaves a wardrobe, without a care of their own. Nor was he made chiefly to minister to the wants of the community. A rational moral being cannot, without infinite wrong, be converted into a mere instrument of others' gratification. He is necessarily an end, not a means. A mind, in which are sown the seeds of wisdom, disinterestedness, firmness of purpose and piety, is worth more than all the outward material interests of a world. It exists for itself, for its own perfection, and must not be enslaved to its own or others' animal wants. You tell me, that a liberal culture is needed for men who are to fill high stations, but not for such as are doomed to vulgar labor. I answer, that man is a greater name than president or king. Truth and goodness are equally precious, in whatever sphere they are found. Besides, men of all conditions sustain equally the relations, which give birth to the highest virtues and demand the highest powers. The laborer is not a mere laborer. He has close, tender, responsible connections with God and his fellow-creatures. He is a son, husband, father, friend and christian. He belongs to a home, a country, a church, a race; and is such a man to be cultivated only for a trade? Was he not sent into the world for a great work? To educate a child perfectly, requires profounder thought, greater wisdom than to govern a state; and for this plain reason, that the interests and wants of the latter are more superficial, coarser and more obvious, than the spiritual capacities, the growth of thought and feeling, and the subtle laws of the mind, which must all be studied and comprehended, before the work of education can be thoroughly performed; and yet to all conditions this greatest work on earth is equally committed by God. What plainer proof do we need that a higher culture, than has yet been dreamt of, is needed by our whole race.

II. I now proceed to inquire into the means by which the self-culture just described, may be promoted; and here I know not where to begin. The subject is so extensive, as well as important, that I feel myself unable to do any justice to it, especially in the limits to which I am confined. I beg you to consider me as presenting but hints, and such as have offered themselves with very little research to my own mind.

And, first, the great means of self-culture, that which includes all the rest, is to fasten on this culture as our great end, to determine deliberately and solemnly, that we will make the most and the best of the powers which God has given us. Without this resolute purpose, the best means are worth little, and with it the poorest become mighty. You may see thousands, with every opportunity of improvement which wealth can gather, with teachers, libraries and apparatus, bringing nothing to pass, and others, with few helps, doing wonders; and simply because the latter are in earnest, and the former not. A man in earnest finds means, or, if he cannot find, creates them. A vigorous purpose makes much out of little, breathes power into weak instruments, disarms difficulties, and even turns them into assistances. Every condition has means of progress, if we have spirit enough to use them. Some volumes have recently been published, giving examples or histories of "knowledge acquired under difficulties;" and it is most animating to see in these, what a resolute man can do for himself.—A great idea, like this of self culture, if seized on clearly and vigorously, burns like a living coal in the soul. He who deliberately adopts a great end, has, by this act, half accomplished it, has scaled the chief barrier to success.

One thing is essential to the strong purpose of self-culture now insisted on, namely, faith in the practicableness of this culture. A great object, to awaken resolute choice, must be seen to be within our reach.—The truth, that progress is the very end of our being, must not be received as a tradition, but comprehended and felt as a reality. Our minds are apt to pine and starve, by being imprisoned within what we have already attained A true faith, looking up to something better, catching glimpses of a distant perfection, prophesying to ourselves improvements proportioned to our conscientious labors, gives energy of purpose, gives wings to the soul; and this faith will continually grow, by acquainting ourselves with our own nature, and with the promises of divine help and immortal life which abound in revelation.

Some are discouraged from proposing to themselves improvement, by the false notion, that the study of books, which their situation denies them, is the all important, and only sufficient means. Let such consider, that the grand volumes, of which all our books are transcripts, I mean, nature, revelation, the human soul, and human life, are freely unfolded to every eye. The great sources of wisdom are experience and observation; and these are denied to none. To open and fix our eyes upon what passes without and within us, is the most fruitful study. Books are chiefly useful, as they help us to interpret what we see and experience. When they absorb men, as they sometimes do, and turn them from observation of nature and life, they generate a learned folly, for which the plain sense of the laborer could not be exchanged but at great loss. It deserves attention that the greatest men have been formed without the studies, which at present are thought by many most needful to improvement. Homer, Plato, Demosthenes, never heard the name of chemistry, and knew less of the solar system, than a boy in our common schools. Not that these sciences are unimportant; but the lesson is, that human improvement never wants the means, where the purpose of it is deep and earnest in the soul.

The purpose of self-culture: this is the life and strength of all the methods we use for our own elevation. I reiterate this principle on account of its great importance; and I would add a remark to prevent its misapprehension. When I speak of the purpose of self-culture, I mean, that it should be sincere. In other words, we must make self-culture really and truly our end, or choose it for its own sake, and not merely as a means or instrument of something else. And here I touch a common and very pernicious error. Not a few persons desire to improve themselves only to get property and to rise in the world; but such do not properly choose improvement, but something outward and foreign to themselves; and so low an impulse can produce only a stinted, partial, uncertain growth. A man, as I have said, is to cultivate himself, because he is a man. He is to start with the conviction, that there is something greater within him than in the whole material creation, than in all the worlds which press on the eye and ear; and that inward improvements have a worth and dignity in themselves, quite distinct from the power they give over outward things. Undoubtedly a man is to labor to better his condition, but first to better himself. If he knows no higher use of his mind than to invent and drudge for his body, his case is desperate as far as culture is concerned.

In these remarks, I do not mean to recommend to the laborer indifference to his outward lot. I hold it important, that every man in every class should possess the means of comfort, of health, of neatness in food and apparel, and of occasional retirement and leisure.—These are good in themselves, to be sought for their own sakes, and still more, they are important means of the self-culture for which I am pleading. A clean, comfortable dwelling, with wholesome meals, is no small aid to intellectual and moral progress. A man living in a damp cellar or a garret open to rain and snow, breathing the foul air of a filthy room, and striving without success to appease hunger on scanty and unsavory food, is in danger of abandoning himself to a desperate, selfish recklessness. Improve, then, your lot. Multiply comforts, and still more, get wealth if you can by honorable means, and if it do not cost too much. A true cultivation of the mind is fitted to forward you in your worldly concerns, and you ought to use it for this end. Only, beware, lest this end master you; lest your motives sink as your condition improves; lest you fall victims to the miserable passion of vying with those around you in show, luxury and expense. Cherish a true respect for yourselves. Feel that your nature is worth more than every thing which is foreign to you. He who has not caught a glimpse of his own rational and spiritual being, of something within himself superior to the world and allied to the divinity, wants the true spring of that purpose of self-culture, on which I have insisted as the first of all the means of improvement.

HORTICULTURAL EXHIBITION.—The Horticultural Association of the valley of the Hudson, will hold its second semi-annual meeting in the city of Albany, at the City-Hall, on the 25th day of June inst. Specimens of early fruits, vegetables, flowers and farm and garden productions of every description, will be received by the committee on the spot the day previous, or before 9 o'clock A. M. on the day of exhibition.

This association, composed of practical men, amateurs and gentlemen resident in all the various counties bordering the Hudson, was established in 1838, and aims at the promotion of horticultural improvement, and the taste for rural affairs generally throughout this portion of the country. At the semi-annual meeting, it is desirable that specimens of the fruits and plants of all the various districts and soils of the Hudson valley should be brought together for comparative exhibition; and the association indulges the hope that all persons friendly to the objects in view, will contribute something for this purpose.

The annual election of officers of the association will also be held at Albany, on the 25th of June. The autumnal exhibition of the association will take place in New-York, about the middle of September next.

j1t A. J. DOWNING, *Cor. Sec'y*, Newburgh.

THOROUGH-BRED IMPROVED SHORT-HORN CATTLE.—The subscriber has recently taken charge of the superior stock of Short-Horn Cattle, bred by L. F. Allen, Esq. on his farm at Grand-Island, in the Niagara river. The original stock from which these have been produced, were selected from among the best animals in the country, and several of them were imported direct from England. As a milking stock, the cows of this herd will challenge competition with those of any other in the United States; several of them being extraordinary milkers, and all of them good. For the making of butter, they have been thoroughly tested, and their dairy excellence is remarkable. Their value in this particular, is fully sustained in the grade animals descended from the bulls of this herd, which have, thus far, without exception, proved the best of milkers. This excellence, possessed in reality by no cow so much as in the pure Short-Horn, has been too much neglected by both English and American breeders, and their value as a dairy stock thus underrated.

In addition to the above, are a select herd of DEVON SHORT-HORNS, bred from two choice pure Devon cows, directly descended from the celebrated herd of Mr. Coke, of Holkham, Eng. These beautiful animals are a cross of different degrees with the pure "Improved Short-Horns," without any admixture of common blood; and are as perfect combinations of excellence in color, hardihood, symmetry and size as can be found.

As the present herd, of all ages, has now attained the number desirable to be kept on the farm, (upwards of forty,) a part of them are offered for sale. Application may be made either personally or by letter, (post-paid,) to SAMUEL ALLEN, Esq. at Black-Rock, N. Y. or to the subscriber on the farm, five miles below, at which a ferry connects with the main shore, on the Erie canal. LEWIS G. COLLINS.

Grand-Island, May 15, 1839.

P. S. A few fine grade animals also for sale. jtf.

FOR SALE—A Splendid Country Seat in the Highlands, on the Hudson River. That beautiful country residence, known by the name of the BEVERLY ESTATE, containing four hundred acres of land; about two hundred of which are fine level arable soil, of an excellent quality, in a good state of cultivation, and not surpassed by any on the river for fertility; the remainder is fine and thrifty timber land. The situation is the most eligible on the Hudson, extending one mile and a half on the river, with a bold shore and convenient dock, nearly opposite West-Point, and within fifty miles of New-York. The prospect is extensive and diversified, reaching from St. Anthony's Peak on the south, to the bay and city of Newburgh on the north. This estate can conveniently be divided into three farms, giving an equal proportion of front on the river, and of arable and timber land to each Almost every enclosure is supplied with living springs of the purest water. There is on said estate a plain house, (formerly the head-quarters of Gen. Arnold;) also out-houses necessary to carry on the business of the farm. The single fact that during the whole time the cholera raged throughout the state, not one case occurred within ten miles of this place, is sufficient to prove the unrivalled salubrity of the situation. The facilities of intercourse with the city, that can be reached in four hours, by means of numerous steam-boats, are great, and daily increasing, both as regards pleasure, and the convenience of a near market for produce of every description.

Rich in historical associations, connected with the glorious struggles for our independence, the Beverly Estate presents to gentlemen of taste and leisure, the rare opportunity of selecting one of the most salubrious and picturesque country seats in the state.

For conditions of sale, apply to STEPHEN A. HALSEY, 189 Water-street, New-York, or RICHARD D. ARDEN, on the adjoining farm. Ardenia, 23d April, 1839. m6t

PACKARD, VAN BENTHUYSEN & Co.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. JULY, 1839. No. 5.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, D. LANDRETH, and M. S. POWELL, seedsmen, Philadelphia; ISRAEL POST, bookseller, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; HOVEY & Co. Merchants' Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are forsale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

The GREAT Business of our Country is Agriculture,—

1. Because it feeds us, and furnishes the materials for our clothing:
2. Because it gives useful employment to five-sixths of our population:
3. Because it is the primary source of our individual and national wealth:
4. Because it is the nursing mother of our manufactures and commerce—neither could prosper or long exist, without it:
5. Because it is essential to national independence.

And hence it follows, as a corollary, and an implied duty, that we should give to this great branch of national industry, all the light, stimulus and reward which its importance demands.

We possess no statistical data of sufficient extent and accuracy to determine the amount of capital invested in our agriculture, the value of its products, the aggregate of its profits, and its consequent relative importance; yet we can form a tolerable estimate in these matters, by an examination of the agricultural statistics of great Britain, which are furnished to our hand, and by then comparing her condition with our own. The following facts are gathered from a letter of James M'Queen addressed to Lord Melbourne, on the subject of the corn laws.

AGRICULTURAL PROPERTY.

Great-Britain and Ireland.	Rental.	Valne at 30 years purchase.
Land,.....................	£63,395,684	£1,901,870,520
Residencies, proprietors, &c.	5,000,000	150,000,000
Timber, produce yearly, ...	3,000,000	90,000,000
Land tax, 1834, ...	1,203,578	34,107,340
Yearly value of tithes......	4,841,053	145,231,590
Poor rates, perpetual charge, exclusive of rent,........	5,434,890	163,046,700
Mines, minerals & fisheries,	3,994,031	119,820,930
Property of proprietors,....	£85,665,658	£2,604,077,080

PRODUCE OF BRITISH AGRICULTURE.

Grain of all sorts,........................	£134,000,000
Potatoes, ...	20,000,000
Hay, grasses, turnips, straw,............	120,300,000
Natural pasture,........................	63,502,000
Butchers' meat, pigs, poultry, game, rabbits, &c................................	82,283,759
Fisheries, food from,....................	12,000,000
Products of the dairy, vegetables & fruits,	48,500,000
Allowed for consumption by farmers, in some articles not enumerated,.........	2,500,000
Wool, hops, seeds, flax, hemp and timber,	21,479,166
Mines, minerals, coals, &c..............	33,970,276
Total produce of agricultnre,............	£539,036,201
Equal to about $2,000,000,000.	

There are employed in these branches of productive labor, which the writer has classed all under agriculture, eighteen thousand families, which, at five and a half persons to each family, gives about ten millions of persons, or five million five hundred thousand effective men and women.

SUMMARY OF POWER EMPLOYED IN AGRICULTURE.

Direct human power, men and women,..	5,500,000
Horses, 1,609,176, each equal to 6 men,..	9,655,068
Oxen, 500,000, each equal to 5 men,.....	2,500,000
Total effective power direct,......	17,655,000

CHARGES ON AGRICULTURE.

On fixed capital, lands, tithes, land tax, mines, fisheries, farm stock, &c........................	£108,993,468
Farm wages, cattle feed, &c.	280,838,628
Tithes, church and highway rates, and labors in mines and fisheries,............	42,228,748
Carried forward,.................	£432,060,844
Brought forward,.................	£432,060,844
Manures, bone dust, lime, wastage and replacing live stock, dead stock, &c......	116,915,280
Charges on agriculture, ...	£548,976,104
Deduct dead stock,.................	21,560,000
Total charges on agriculture, ...	£527,416,104

SUMMARY—AGRICULTURE.

Total produce, ...	£539,036,201
Total charges, rent at 3 per cent,......	527,416,104
Farmers apparent profit,.......	£11,620,097

The poor rates are paid as follows:

Property in land, and tax on houses and occupiers,.........................	£8,099,414
All other classes of property,............	7,226,406
Total,.........................	£15,325,720
Deduct charges and allowances,...	780,000
Nett produce, ...	£14,545,580

MANUFACTURES.

The capital vested in, and charges on, the manufactures of the United Kingdom, are stated to amount, in the aggregate, to......................	£205,773,872
And their total produce per annum, to....	259,412,709

The total number of persons engaged in manufactures is stated at 8,200,000, one-half of which are effective men. These added to the steam power employed, give an aggregate power equal to 4,500,000 effective men.—With the addition that has recently been made to manufactures, the writer states the comparison as below.

	Capital.	*Produce.*
Agriculture,.........	£3,258,910,810	£539,036,201
Manufactures,.......	217,773,872	271,416,709

or 15 to 1 in capital, and double in produce, with this further superiority, that in the agricultural capital it is all fixed and real. Agriculture expends nothing abroad, while manufactures pay to foreigners £20,000,000 annually for raw materials.

COMMERCE.

The total exports for 1836, amounted,

To foreign countries, to	£37,833,000
To her colonies, to..........	15,532,566
	£53,368,566

Of these £12,425,605 (about $54,000,000,) were to the United States, for which she received principally our public stocks in payment.

It appears from the preceding data, that the capital invested in British agriculture is fifteen times as great as that which is invested in British manufactures, although the latter excel in magnitude the manufactures of any other nation; that British agriculture pays most of the burthens of the government, supports a privileged clergy, and contributes more than thirty millions of dollars annually to her poor rates;—that its products exceed in value, *more than fourteen times* the whole amount of her exports to foreign countries, although her commerce exceeds in that of any other nation;—and that her agricultural capital is fixed, and abiding as her islands, while the capital vested in her commerce and manufactures is subject to many contingencies, which may impair or destroy it.

Now let us apply these facts to our own condition.—We will assume the population of both countries to be the same. Ten millions or one-half of her population are assigned to agriculture. With the collateral branches, as mines, fisheries, &c. which are classed under agriculture by Mr. McQueen, fifteen millions of our population may be assigned to this class. And the presumption is, that our agricultural capital and agricultural products, overbalance the capital and products of manufactures and commerce, as much, nay more, than they do in Great-Britain. From this view of the subject, it will be seen, that agriculture is really the GREAT business of this nation; that it is worthy of the most liberal patronage of our governments, state and national; that it ought to be enlightened, by a better education to the agricultural class; that it ought to be encouraged and patronized, by public bounties and rewards; that it ought to be respected, for its highly salutary influence upon our republican institutions, and upon the good order of society; and finally, that it ought to be honored, at least according to its intrinsic merits, that it may be more followed, by men who have minds, as well as hands, to accelerate its improvement.

We mean no disrespect, by these remarks, to the merchant or the manufacturer. We are not in the way of believing, that by attempting to raise one class, we sink the other classes. Manufactures and commerce are the hands and the legs, while agriculture is the body. They are reciprocally useful to each other. The body may sustain life without the limbs, but the limbs will perish without the aliment which they derive from the body. But we believe the other classes have numerous and efficient advocates, who are able to take care, and who do take care of their interests; and that agriculture demeans herself, and compromits the best interests of the state, by her modest, passive, degrading acquiescense in total neglect. We wish to raise the agriculturists of our country to the condition which belongs to them—to that of intelligent, prosperous, high principled men—who know their rights and their duties, and will fearlessly assert the one and faithfully perform the other. Then will our agriculture be made to double and treble its products—to compete with the agriculture of other countries, and to supply all our wants; then will party interest be made to bend to the public good, and riot and outrage be made to give place to law and good order; then shall we truly become an independent nation, rich in all the elements of human happiness.—Even if we fail in all these fond anticipations, we can lose nothing by making the effort. We must be gainers in a less or greater degree.

Lawyers and Farmers.

We perceive by the news journals, that there were about one hundred attorneys and counsellors graduated or licensed, at the May term of the Supreme Court.—Assuming this to be the average number graduated at each term, the terms being four in a year, and counting only the number of attorneys, the annual accession to this corps must be two hundred! And these two hundred lawyers are to live and grow rich—how? By any branch of productive industry? by adding to the wealth, the quiet and the substantial enjoyments of society? We fear not. They must live by their profession, honestly if they can—but they *must* live; and with the law-making, law-dispensing, and fee-regulating powers virtually in their own hands, is it to be wondered, that litigation increases, that the delays of the law are multiplied, and the expenses of justice augmented? If one lawyer drains from the earnings of labor, two or three thousand dollars a year, what amount of these earnings will it require to support, in legal style, ten thousand lawyers? The answer, by the rule of three, would be twenty to thirty millions of dollars. Verily we may have too much of a good thing. Geo. Stevens, in his ingenious lecture upon heads, compares the law to fire or water,—a very good servant, but a very hard master; very useful and pleasant in moderate quantities, but extremely inconvenient and mischievous when in excess. We have seen in the print shops, a carricature, very illustrative of George Stevens' comparison—a portly, well dressed gentleman *going to law*—and a meagre, ragged skeleton of a man who *had been to law.*

We are by no means disposed to fault the young gentlemen who are thus crowding to the temple of the law, for fame and fortune, however we may lament the fatuity which impels them on. Law is the great avenue to office, to wealth, to distinction, to fashion—by common consent—and the fond mistaken parents are generally as sanguine in their anticipations of honor and distinction as the sons. There are many distinguished and eminent lawyers, useful and worthy members of society, and there are a great many who are quite otherwise, whose *wants*, rather than their *wishes*, lead very much to the increase of litigation—but who might have been useful members of the commonwealth, had they chosen a different and more suitable sphere of action.

Now, if agriculture held the rank which legitimately belongs to it in the social scale—if it had schools of instruction combining the useful with the agreeable, it is not improbable, that one-half of those who are annually crowding and burthening the legal profession, would become useful cultivators of the soil. What a vast improvement would this effect, in a few years, in the condition of our state—in its agriculture, the basis of its wealth, in the intellectual condition of its inhabitants, and in their moral and economical habits. Such schools, should they ever be established among us, either by the wisdom of the legislature, or the well directed efforts of individual patriotism, would soon annually scatter over the state, hundreds of young men, distinguished alike for strength of mind, vigor of constitution, and exemplary habits. These would carry with them a practical knowledge of the best modes of farming, the best implements, the best seeds, the best fruits, and the best breeds of animals; and each in his future sphere of action, would become a living proof, to those around him, of the practicability of improving our agriculture, and an example to them of good habits and good management. Wherever we find a good farmer, we see the benefits of his example in most of those around him, which diminishes as we recede. Were the good farmers multiplied at the rate of four or eight hundred a year, as they might be through the influence of schools of practical and scientific agriculture, the advantages to the state would be incalculably great.

We take this occasion to apologize for the caption—"*Privileged Classes*"—which was inadvertently placed over an editorial article in our May number, as liable to a construction which we did not intend to give it.—We are not agrarian in our opinions. We consider all professions open to free competition, and as useful, when limited in their sphere and numbers. If there is a privileged class in our community, it is the intelligent, independent tillers of the soil; not that they are privileged by law, or by popular favor—but that they are privileged by their Creator, in the enjoyment of a greater share of temporal blessings, the natural result of sober, industrious and contented habits—than perhaps any other class in the community. Our wish is to see them intelligent and independent, that they may enjoy the reward, and the state the benefit. We ask for them no exclusive public encouragement or bounty; but merely some of the crumbs which fall from the public table, and which have heretofore, at least in some instances, been lavishly, if not wickedly, squandered upon far less worthy objects. We wish to see agriculture brought forward from the shade, from the back ground, where it has been too long obscured and degraded by ignorance and servile apathy—and to see the public bounty, like the sun and the rains, which fructify the earth and cause it to bring forth food for man, dispensed alike to all lasses of the community.

Geological Report.

We resume our notice of this report, and of Dr. Beck's communication.

Iron—The northern and southern sections of the state abound in this metal.

> "While at the north we have the immense beds of the magnetic oxide, at Newcomb, in Essex county, one of which is described by Mr. Hall, as being more than a mile in length, and more than five hundred feet in breadth, besides others of less magnitude in various parts of the same county, and in those of Clinton and Franklin, and the beds of specular iron ore in St. Lawrence; we have at the south the vast deposites of magnetic oxide in Orange county, and of hematite in the county of Dutchess."

Iron ores also occur in Columbia, Rockland, Richmond and Washington.

Manganese is found in Lewis, Essex, Westchester, Columbia and Dutchess, and especially in the two latter counties, the quantities that could be obtained, at very little expense, are estimated by Prof. Mather, at 50,000 tons, worth, if carefully prepared, $20 per ton, or $1,000,000. The oxide of manganese is extensively used in the preparation of chlorine for bleaching, and in the manufacture of glass.

Lead is found in Columbia, Lewis, St. Lawrence, Ulster and Sullivan.

The next communication in the report, is from T. A. Conrad, on the Palæontological Department of the survey. As this would interest but few of our readers, we pass to

PROF. MATHER'S REPORT,

On the economical geology of New-York, Westchester, Putnam, Rockland and Orange, comprising the first district, with two supplemental reports, from Drs. Horton and Gale, on the descriptive geology of Orange and New-York. The counties lying east of the Hudson, and those on the west border, are considered separately.

The sources of mineral riches in this district are very great, and are being made subservient to profit, and their advantages are susceptible of very great extension.

The counties of Rockland and Orange are classed under four divisions, in regard to aspect and agricultural features, and mineral products. "They are the mountainous region called the Highlands, and composed of primitive rocks; the slate and graywacke regions of Orange county, the red sandstone and the trap of Rockland county." On the eastern shore of the Hudson, the soil is more similar, being "derived from the disintegration of the contiguous rocks, and of the pebbles and boulders of materials transported from a greater or less distance from the N. N. W. by some natural causes." They contain all the *mineral* elements of fertility; while the extensive salt marshes and mud flats, on the coast, and the bog meadows of the interior, furnish abundance of the *vegetable* elements—so that it would seem, that if those elements were duly mixed and managed, the soil might be rendered highly productive. The same remark will apply to many districts of our country.—The admixture of earthy matters, which, where wanted, are generally found in contiguity with each other; the vegetable matters which abound in our swamps and marshes; the marl, lime and gypsum which are scattered over our state, for the transporting of which we have every facility; and the animal manures of our farm stock, afford abundant materials for increasing and perpetuating the fertility and productiveness of the soil, and of multiplying the comforts and enjoyments of our population. We lack only the knowledge and the industry necessary properly to combine and to develop the elements of wealth and happiness which are scattered around us, designed for our use.

Independent of the great means which these counties afford, of increasing and perpetuating the fertility of the soil, their other mineral sources of wealth are far greater, we believe, than our readers are aware of.—We will briefly notice some of the most prominent. And first,

Peat—Great tracts of this are found in the eastern counties, which are coming into use, and may be mostly employed as fuel—that on the borders of the river being more fibrous and inferior to that which occurs in the interior. The Professor estimates the quantity in the three eastern counties, New-York, Westchester and Putnam, at 2,000,000 of cords on the border of the river, and 1,160,000 cords in the interior. Considered in reference to its fertilizing properties in the soil, the value of this vegetable material will be immense. The drowned land tract, in Orange, which comprises some thousand acres, is a bed of peat from three feet to several yards in depth, the number of cords not estimated.—This has proved, on trial, a good fuel. The total cords of peat, however, in Orange and Rockland, is put down at 26,140,000 cords, or 72,000,000 chaldrons. It costs, for digging, curing and marketing, $1.25 per chaldron, and sells in New-York, at $3, leaving $1.75 profit to the proprietor.

Clay is extensively employed as a means of creating wealth, in the manufacture of brick. The extent of this business will appear from the following estimate of the number annually made in each county.

In Westchester,	38,700,000
In Putnam,	3,200,000
In Rockland,	12,000,000
In Orange,	9,760,000
	63,660,000

There is employed in this business a vast capital, and a great number of laborers, both in the manufacture and transportation. At $5 per thousand, the income from this manufacture would amount to $318,300 per annum. And if we add to this estimate, the bricks manufactured in Dutchess, Columbia, Rensselaer, Albany, Greene and Ulster, the amount earned in this branch of industry will exceed a million of dollars per annum.

The clays of these counties are also used in coarse pottery. They are used, too, to a limited extent, to improve the texture and quality of light lands; a use to which they are admirably adapted as we have found by experience, when they contain, as the blue and gray kinds generally do, a portion of carbonate of lime.

Marl has not yet been found in any considerable quantities, either in the counties of New-York, Westchester or Putnam; but it is found in almost every town in the county of Orange, where it either lies naked, or is covered by water, or bog earth or peat. In the few experiments which have been made of this material, as a fertilizer of the soil, we are sorry to see the professor remark, its effects have generally been unfavorable.—His impression is, that too much has been applied, whereby vegetation has been as much prejudiced as if too much quick lime had been applied. A case is cited where marl was applied twenty-nine years ago. Nothing would grow on the field for many years; but latterly corn and wheat have grown well, and yielded bountifully. Too much calcareous matter is as prejudicial to vegetation, as too much sand or too much clay. There are entire districts rendered infertile in the south, by the too great portion of carbonate of lime with which the soil abounds. Two per cent of the tillable stratum, of calcareous earth, suffices for all the useful purposes of vegetation, though twelve per cent, we believe, has not proved hurtful. Soils may naturally contain enough of this earth. Marls differ in the quantity of calcareous matter which they contain, and there is often blended in their composition matters that are prejudicial to healthful vegetation. It is prudent, therefore, to experiment with them on a small scale, till their properties, and those of the soil, are well ascertained, and then to apply them on a larger scale, in the proportions, and in the manner, found to be most serviceable. It would be well to experiment with them as a top dressing upon meadows or pastures, by which they would be deprived of their deleterious properties, and thereby become fitted to improve the soil, after the lapse of a year or years, when they are ploughed under. There is not a doubt but marls are calculated to impart fertility to all soils which are naturally deficient in calcareous matters. We want their analysis, and that of the soils, to know where and how, and in what quantities, to apply them to advantage.

Gypsum.—Although none has been found in this district, the annual amount paid for it in Orange alone, is estimated to cost more than $41,000.

Limestone abounds in all the counties of this district, and is extensively wrought as an article of commerce. The Professor is in the habit of estimating the profit of the lime and other stone quarries, provided the material was all marketed. In this way he states the nett value of a limestone quarry in Westchester, estimating it at $1.50 per barrel, at about $34,000. This is something in the manner of the milk-maid who counted her chickens before they were hatched, or of the speculator in western lands, who foots his profits before he has sold out, or got his pay. The lime of these counties, however, without looking to their ultimate value, affords the material for a profitable commerce, as a building material, and which will no doubt come into use extensively as a fertilizer of the soil, for which purpose it is already partially employed.

The new mode of burning limestone, with the aid of anthracite coal, and in perpetual kilns, as already noticed, from Dr. Beck's report, is one of great economy, and which promises ultimately to reduce the price of this necessary article, especially upon navigable waters. The expense of quarrying the stone, at one of the localities, is estimated at nine cents per barrel, that of the coal at 25 cents per barrel, and the price of the lime in market at $1.50; thus giving, after deducting every expense, including teams, attendance, freight, casks and cooperage, a nett profit of 53 cents per barrel. The amount of lime burnt in Orange county last year, is estimated by Dr. Horton, at 182,650 bushels.

Granite, and much of good quality as a building material, and convenient for water transportation, is found in all the counties of this geological district. Several quarries are already opened and profitably wrought, and many localities of great extent, are pointed out, and estimated upon, by the geologist.

> "It is estimated," says the report, "that several millions of dollars are annually paid out of the city of New-York, and the towns on the Hudson river, for building stone, brought from beyond the limits of the state, while we have within our own boundaries, and near our markets, inexhaustible supplies, of equally good quality, which can be quarried, shipped and hauled, at less expense than the stone we now import from Maine, New-Hampshire, Massachusetts and Connecticut. The granites of the Hudson river *must*, then, soon be wrought and sent to market, and the quarries will become very valuable."

Gneis abounds in most parts of this district. Several quarries are noticed, lying on the banks of and contiguous to the Hudson river, and many other localities are indicated. This stone is extensively employed in the Croton aqueduct, in the construction of bridges, aqueducts, &c.

We omit a notice of other rocks, and of the metallic ores, which are found in this district, which are numerous, and the quantity, particularly of iron, very extensive—one locality, or vein, being computed to contain 5,600,000 tons of iron. The red sand stone is worked to a great extent in Rockland, where there are thirty-one quarries wrought, and which yielded last year 62,000 feet of slabs, valued, with the rubble, at $18,987.

Silk Companies.

We have lately had sent to us, a prospectus of the New-York and Long-Island Silk Growing and Manufacturing Company, capital $60,000. We are in the main opposed to all joint stock companies, for any object that comes within the reach of individual means and enterprise, and particularly such as are likely to conflict with household industry, like those which associate for the culture of the mulberry and the tending of silk worms. This we consider legitimately a family business, and one which ought to be encouraged as such. The organization of joint stock companies for the carrying on of a business which the most humble farmer has the means of profitably conducting, leads to the impression, that great capital or great skill is required in the business, and that individuals cannot compete with companies; and thereby deters hundreds and thousands from entering into a business which could be managed by them with great pecuniary advantage. We do not think that corporate bodies should be created merely for the individual profit of the stockholders—but that the public interest—the interest of the many, is the only justifiable ground for granting corporate privileges.

But the New-York and Long-Island company, if we are rightly apprised of their plan, forms an exception to our remarks. The company, we understand, have purchased a farm on Long Island, three miles from N. York, which they have planted, and intend to plant, with mulberry trees, for the purpose of manufacturing silk; and they design to have the business of picking the leaves, tending the worms, &c. managed by poor widows and fatherless children from the great city.—Plain cheap cottages are to be erected for these widows, with small gardens attached, to occupy their leisure time, and furnish subsistence. In this way, capital will be usefully employed, to promote industry in the young, afford profitable employment to the indigent, profit to the stockholders, and benefit to the public at large.—Under this view of the subject, we commend this stock to the notice of capitalists, as affording a safe, meritorious, and we think profitable investment.

Mr. Colman's Second Report.

The second report of Mr. Colman, on the agriculture of Massachusetts, is principally devoted to a survey of the county of Berkshire, which lies upon the eastern border of our state, though it embraces much other incidental and interesting matter. As the report comprises 200 8vo. pages, we are necessarily restricted to an outline of its most important matter.

Berkshire county is more than 50 miles long, and has an average breadth of about 20 miles, and a population of nearly 40,000. About one-half of the county is improved, say 207,000 acres, of which 117,000 acres are pasturage, 27,000 tillage, and the residue in meadow or mowing. It is of course a grazing district; its dairies are extensive, and its flocks of sheep numerous.

The surface of the county is broken and mountainous; but it is everywhere intersected by rich valleys, and fine streams of water, which afford numerous mill sites, which are extensively improved for hydraulic purposes. The soil in the valleys is generally rich and productive, and the hills and mountains yield excellent grass and pasture. The inhabitants are intelligent, enterprising and prosperous. The crops are those usually cultivated in our latitude; and the produce of the soil is generally consumed by its population—the products of the dairy, cattle, and manufactured goods forming its principal articles of export.

The return of crops does not generally indicate a high state of tillage husbandry, though in some cases the yield is bountiful. Oats, potatoes and ruta baga seem to make the best returns, though corn has, in many cases, given a great crop, and in one case as high as 110 bushels. Some crops of potatoes have gone to 500 and 560 bushels, and the ruta baga as high as 1,200 or 1,300 bushels. But the average returns are less than half of these quantities. These great products serve, however, to show what can be done, and what will more generally be done, under an improved state of husbandry, when bad farmers can be persuaded, or taught, to imitate the good ones.

The common rotation is stated to be, corn or potatoes, generally manured; then oats; third crop wheat or other grain, with grass seeds. The value of clover does not seem to be appreciated, as an alternating crop, or as a fertilizer of the soil, as we do not find it mentioned under rotation of crops. We would barely remark, that three exhausting crops in succession is not considered an indication of good husbandry. Twenty-three pages of the report are principally taken up with statements of expenses and profits of crops. The footings indicate, that the profit has been greatest on ruta baga, and that potatoes and corn are next in value; and generally, the profit is in proportion to the expense—the greatest outlay making the most profitable return. A case is quoted, where 40 bushels of wheat were taken from an acre, which had been planted, the preceding year, with corn upon greensward; and the great product is ascribed to the fact, that the ploughing for the wheat was superficial, leaving the decomposing sod still below, where the roots of the wheat would want and seek for it, and where it would escape the wasting influence of the sun and atmosphere. This mode of economizing the vegetable matter of the sod was strongly inculcated by the late John Lorrain, and has been frequently recommended in the Cultivator.

A practice is mentioned, of alternating corn and potatoes in the same row. The corn is planted 3 feet 6 inches apart, and a hill of potatoes between every two hills of corn. In this way the cultivator thinks he gets 150 bushels of potatoes on an acre, without materially diminishing his corn crop. We are inclined to think, that the better practice is to alternate corn and potato rows, two of each, or one of potatoes and two of corn. The corn is undoubtedly benefitted by the exposure, which is here had, to light, heat and air, while the shade of the corn does but little prejudice to the potatoe crop. Such was the practice of Lorrain, and such has been the practice of others, with undoubted advantage.

DAIRY HUSBANDRY.

This is a great dairy county, the quantity of butter and cheese made is large, and the quality good. The annual keep of a cow is estimated at about $20, and her products, in calf, cheese, butter and pork, is from 30 to 50 dollars, leaving a profit for attention of 15 to 30 dollars, according to the goodness of the cow and the goodness of her keep. Extra feed, judiciously dispensed, is always profitably applied to milch cows, as the extra food is almost wholly converted into milk. Thus a herd of 20 cows gives to the dairyman a mean average profit of at least $400. Three acres of pasture are allowed to a cow. On 22 farms in the town of Cheshire, there are kept 414 cows, which gave in 1837–8 the following produce:

New milk cheese, ...	300,000 lbs.	
Skim do	11,050 "	
	————	311,000 lbs.
Butter sold, ...		19,050 "

We quote the case of an individual farmer in this town, as evidence of the profits of dairy husbandry, and as a notable example of the reward of persevering and honest industry, and of rural comfort and independence.

"This farmer," says the report, "has now a dairy of 24 cows, and they produce a cheese per day, weighing about 100 lbs. Supposing that it requires but a gallon of milk to produce one pound of cheese, this would give 400 quarts of milk per day, or at the rate of 16⅔ to a cow. These cows are all of native stock; most of them raised by himself. His average product of new milk cheese to a cow, in a season, is perhaps between 500 and 600 lbs. Last year the actual yield was 598 lbs. to a cow. Of his 24 cows last year, two were heifers of two years old. Four years since, he was the owner of a cow, whose milk, in the best season, amounted, by actual weight, to 70 lbs. a day. During the time of her greatest yield, she was fed with four pails of cheese whey, and some rye meal. She was of native stock. This farmer has a heifer from her, which gives 60 lbs. of milk per day. He prefers heifers to 'come in' at two years old. Their milking properties are in this way improved. * * *

"The establishment of this farmer," continues the report, "is substantial and independent. As far as the common comforts of life are concerned, little more seems to be desired. Good air, good water, plenty of bread, plenty of fuel, plain and substantial clothing made by the hands of his own family, and the product in a great measure of their own flocks and fields; an estate which he can call his own with truth; because it has been purchased not by fraudulent speculation upon other people's earnings, but by the healthful toil of his own muscles, and the sweat of his own brow; luxuriant pastures filled with those beneficent animals, who are nourished by his kindness, and settle their bills in the most honorable manner every night and morning; and a clean dairy room of ample dimensions, and exemplary neatness, with its numerous shelves, loaded with the richest produce, and speaking as well for the in door as the out door management; these features combined in this picture present one of those beautiful examples of rural independence, and the bountiful rewards with which Providence is pleased to crown industry, frugality and good management, with which I am happy to say the county of Berkshire is everywhere sprinkled over, even on its high mountain summits, as well as on its fertile alluvions, and its peaceful and secluded valleys. The independent proprietor of this establishment is now sixty-six years old. At the age of nineteen he was not the owner of a dollar. He now admits himself worth thirty thousand dollars; and all this, with the exception of less than fifteen hundred dollars, is the produce of his own farming industry, as he has never engaged in any speculation whatever. A higher good than all of this is found, in the fact which he added with an honest pride and enviable pleasure, that he had brought up eight children in the habits of honest industry; and not one of them had ever disgraced his parents.

"The standard of dollars and cents is a very imperfect standard, by which to measure the prosperity of such a man. It is a prosperity flowing from deeper, purer and more enduring sources; from a competency for the evening of life, earned by honest labor; a mind unembarrassed by the fear of want and the vexatious caprices of trade and speculation; and a grateful sense of the kindness of that just and beneficent Providence, whose blessings have rendered his peaceful and unpretending labors successful."

The North Devon cattle are said to prevail generally throughout New-England, though in the main, we suspect they have degenerated from want of attention in breeding from select animals, and by crossing with the long-horns. Some of the cows possess uncommon properties for milk, and if these were carefully crossed with approved bulls of a good milk breed, we have little doubt, but the progeny would soon be in high reputation, as dairy stock, rivalling, perhaps, for this purpose, any breed which we are importing at vast expense from the other side of the Atlantic. Some of the cows noted in the report, have given from 200 to 300 lbs. and one as high as 425 lbs. of butter in a year. Such a cow is worth more, for the profits of the dairy, than ten poor milkers, and her stock ought to be sedulously preserved.

The commissioner here introduces a notice of Mr Jaques' Cream-Pot breed, an eminent farmer and breeder, at the Ten Hill stock farm, near Boston. Mr. Jaques obtained a remarkable cow, by a cross of the Durham upon native breed, which gave him nine pounds of butter in three days; and from this beginning has sprung his *Cream-Pot* breed, the cream of some of which gives 80 per cent of butter. Mr. J. has 40 cows and heifers, and 10 bulls of this breed. Their good properties do not consist so much in the quantity of milk they yield, as in its richness. We have found that while the milk of one of our cows gave but nine per cent of cream, the milk of another, at the same time, and upon the same feed, gave fifteen per cent of cream. The *quality* of a cow's milk does not receive that attention which it merits, in our estimate of dairy cows. We have half a dozen cows, which we esteem superior milkers, and superior in form and appearance, which we have bred from an individual cow, and put to good bulls. If farmers would carefully breed from the best milkers, they would be able to make within themselves, in a few years, a vast improvement in their dairy stock.

The properties to be sought for in neat cattle, differ somewhat according to the purpose for which they are wanted—whether for the pail, the draft, or fattening. And these three properties are very seldom, if ever, found united in a single individual. A cow that takes on flesh rapidly, when in milk, cannot be expected to be a deep milker, unless she is very highly fed. Her food cannot be expected to be converted into both meat and milk; and as the disposition to the one or the other preponderates, so the other must decline. The Herefords, a branch of the Devons, which combine much of the quickness of the Devons in the yoke, with the size and strength of the long horns, and which very much resemble, in size and strength the best working oxen in New-England, and of Madison and other hilly counties of our state, are considered light milkers; and yet they afford probably the best working oxen, and if not the most, are certainly a very profitable stock to feed for the butcher. Of the seven principal prizes awarded at the last Smithfield (London) show of fat cattle, the Herefords carried off five prizes, the Devons one and the short horns one. The first animals of pure Herefords which have fallen under our notice, were a young bull and heifer lately imported, and now owned by our neighbor C. N. Bement.

For the dairy, a general preference is given, says the commissioner, to the common native stock of the country, in which the Devon blood predominates; but such are not preferred as breeders of other but dairy stock. Mr. Coleman quotes from English authority the following statement of the proportion of butter to milk, drawn promiscuously from six different short horns; the milk was one quart in each case.

No. 1 gave	3oz.	6dwt.	No. 4,	1oz.	10dwt.
2 "	1 "	6 "	5,	1 "	14 "
3 "	1 "	12 "	6,	1 "	6 "

Thus showing, that one quart of one cow's milk gave nearly as much butter as three quarts of another cow's milk. The lactometer affords a ready means of determining the relative proportions of cream afforded by the different cows: but then, to show an accurate result, the milk should all be taken alike, that is, from the first or last that is drawn from the udder at a milking,—for the two samples differ very greatly in their quality—the first drawn being very deficient in butricious properties, sometimes one or two hundred per cent, to the strippings. The lactometer is a glass tube, sold by seedsmen, and sometimes by apothecaries, graduated into 100 parts. The milk is put into this, and having had time to rise, the per cent of cream upon the top is ascertained by holding the glass up to the light.

Mr. Colman gives one case in which an experiment was made in soiling a small herd of cows, the cows were kept wholly in the stable, and fed wholly with green cut food. The result was, three gave 389 pounds of butter in 13 weeks, lacking one of being 30 lbs. a week, or 10 pounds a week to each cow. We think a half-soiling system, which affords the cows a range and exercise in the day time, and extra green food at night, is the preferable mode. When the pasture is short or deficient, an extra feed of cut grass at night, adds greatly to the milk, and is a very profitable mode of appropriating a lucern or clover field. We have in this way kept half a dozen cows upon an acre of lucern most of the season. The cows had a run of four or five acres of pasture, and were fed night and morning with as much cut lucern as they would eat up clean. When the acre had been cut over, the ground first cut was in condition for a second cutting.

The commissioner recommends more attention to the raising of calves, by dairy farmers, not only to perpetuate and improve the dairy breed, but as a matter of pecuniary profit; and he cites cases of prime heifers, two years old, bringing with their first calf thirty-five dollars. But the commissioner recommends that which, if commendable, we doubt if it will be carried into effect by farmers generally, viz: that it is best to raise calves in the stall or yard the first season, where they are to be fed with hay, carrots and potatoes cut fine. These roots are scarce at the season of rearing calves, the expense of rearing is increased, and besides, we think the animals are deprived of the exercise of their natural habits—free exercise in the open air, and feeding upon the fresh herbage, destined to become their principal food. Good pasture will keep early calves in a growing healthy condition after they are 12 or 16 weeks old; and we should consider it better, if it is designed to make a superior animal, to give extra feed with the natural food, than to depend wholly upon what may be termed artificial.

In dairy management, the report recommends perfect cleanliness, a pure air in the milk-room, and the churning of cream while fresh, as having a great influence in the quality of the product. Two important suggestions are here omitted; the first is, that after the preceding requisites have been duly observed, still that the quality of the butter will depend much upon the temperature of the cream when submitted to the operation of churning. It has been demonstrated by repeated experiments, that the cream ought to be of a temperature between 56 and 62° of Fahrenheit; that if it is below this, the process of churning becomes more tedious, and the butter of but second quality; and that, as the temperature rises above 62, the butter becomes white, frothy and inferior. In the second place, unless the butter milk is completely extracted, and the salt dissolved and incorporated with the butter, before it is packed down, and air afterwards excluded from the mass, it will not *keep* good, though it be good when laid down.

Mr. Colman recommends the cheese shelves figured and described in our second volume, which are suspended on a horizontal central bar, and upon which many cheeses may be turned by a boy in one operation.

The swine of Berkshire are not highly recommended; although pork is one of the staple products of a dairy district. The Byfield, China, Mocho, grass breed, and Berkshire have been partially introduced. Mr. C. says the Berkshire "is the best hog we have among us." One hog is generally kept to four cows. A shoat weighing 70 lbs. in the spring is made to weigh 250 lbs. in the fall, upon the slops of the dairy of four cows.

A successful pork fatter is noticed whose process of fattening is described as follows:

"As soon as the pasture will afford a good bite of grass, he turns them in where they can have plenty of clover and water. He is careful to salt them once a week, if the season is wet; and changes them from one pasture to another, as he does sheep or other stock, which is of much importance during the summer. As soon as he gathers his harvest, he gives them the stubbles. When these are well gleaned, he gives them corn cut up by the ground for a few days, as it is dangerous to keep them closely shut up and feed them highly in the beginning; having no exercise it tends to produce the blind staggers. In order to remedy this, they must be put upon thin food and have as much salt as they will eat. He commences steaming potatoes for his hogs the first of October, his ruta baga not being then matured; he mashes them fine; puts nothing with them but the sour milk from six cows, and four quarts of salt to a box of 28 bushels. This feed he continues three weeks. Afterwards he commences steaming ruta baga, and continues this feed until the first of December, which is five weeks. He puts with the ruta baga, after being mashed fine, four quarts of salt, and three bushels of oats and peas ground together, into a box of 28 bushels. On this feed they do extremely well. This feed he continues till the 25th December, and then finishes off with meal and corn."

In this way he makes his hogs, the age is not mentioned, average over 300 lbs. There are three facts worth noticing in this mode of fattening swine, in general, we believe, not sufficiently regarded or practised, and which evidently add materially to the profits of the business.

1. Good clover pasture, and a change of pasture, incontestibly beneficial to all other farm stock.
2. A constant and plentiful supply of salt—as essential to the digestive functions and health of the brute as it is to the health and appetite of man. And,
3. The economy of fattening upon roots. Potatoes, to be sure, have long been in use as hog feed; but the use of ruta baga can hardly be said to have commenced with us. These, beets, carrots and parsnips, are believed to be all as nutritious, and as profitably cultivated for swine, as the potato. Our pork may be almost wholly made from the slops of the dairy, clover, roots and apples, with far greater economy than it can be made from corn or other grain; and the more improved mode is now, to give corn and grain only during the last weeks of the fattening process.

We intend to resume the review of this report in our next.

Criteria of Dairy Stock.

We copy from the Farmers' Magazine, the following scale of points of Jersey dairy stock, which has special reference *to the producing butter and milk*, but is not designed to apply to cattle for draught or fatting.

SCALE OF POINTS FOR BULLS.	*Points.*
Art. I. Purity of breed on male and female sides, reputed for having produced rich and yellow butter,	4
II. Head fine and tapering, cheek small, muzzle fine, and encircled with white, nostril high and open, horns polished, crumpled, not too thick at the base, and tapering, tippled with black, ears small, of an orange colour within, eye full and lively,	8
III. Neck fine, and lightly placed on the shoulders, chest broad, barrel hooped and deep, well ribbed home to the hips,	3
IV. Back straight from the wethers to the setting on of the tail, at right angles to the tail. Tail fine, hanging two inches below the hock,	3
V. Hide thin and moveable, mellow, well covered with a fine soft hair of a good colour,	3
VI. Fore arm large and powerful, legs short and straight, swelling and full above the knee, and fine below it,	2
VII. Hind quarters, from the huckle to the point of the rump, long and well filled up; the legs not to cross behind in walking,	2
VIII. Growth,	1
IX. General appearance,	2
Perfection,	28

No prize to be awarded to a bull having less than 20 points.

SCALE OF POINTS FOR COWS AND HEIFERS.	
Art. I. Breed, on male and female sides, reputed for producing rich and yellow butter,	4
II. Head small, fine and tapering, eye full and lively, muzzle fine and encircled with white, horns polished and a little crumpled, tippled with black, ears small, of an orange colour within,	8
III. Back straight from the wethers to the setting on of the tail, chest deep and nearly of a line with the belly,	2
IV. Hide thin, moveable, but not too loose, well covered with fine and short hair of good colour,	2
V. Barrel hooped and deep, well ribbed home, having but little space between the ribs and hips, tail fine, hanging two inches below the hock,	5
VI. Fore legs straight and fine, thighs full and long, close together when viewed from behind; hind legs short, and bones rather fine; hoof small, hind legs not to cross in walking,	2
VII. Udder full, well up behind; teats square and largely placed, being wide apart; milk veins large and swelling,	4
VIII. Growth,	1
IX. General appearance,	2
Perfection for cows,	30

Two points shall be deducted for the number required for the perfection of heifers, as their udders and milk veins cannot be fully disclosed.

No prize shall be awarded to cows having less than 21, or to heifers having less than 19 points.

Portable Manures.

This is a term given in England to what we call *concentrated manures*, that is, bone dust, horn shavings, poudrette, urette, &c. They are probably there called *portable*, for the reason, that they may be transported a distance at one-tenth, or even one-twentieth of the expense that their equivalent of stable manure could be transported. Hence they are in great demand, in Great-Britain; and the quantity used may be judged of from the fact, that that country is now paying annually, £200,000 to foreign countries, equal to $888,000, for bones to fertilize her lands; while the high price of the article has led to the most careful collection of them in every part of the United Kingdom. In 1827, Mr. Huskinson gave it as his opinion, in the House of Commons, that the use of bone dust, in British husbandry, occasioned an additional produce of 500,000 quarters of corn, (four millions of bushels,) and the writer in the Irish Farmers' Magazine, who states the facts we are narrating, adds, "it is not too much to suppose, that the quantity has since been increased four fold;" that is, that the use of bone dust in British husbandry is now annually adding sixteen millions of bushels of grain to her agricultural products! What a lesson this for our farmers, who are exhausting the patrimony which Providence gave for coming generations!

> "The most active ingredients in bone dust," says the writer to whom we refer, "are phosphoric acid and ammonia, combined with lime and carbon; and it is to the action of these upon each other, and the influences of the changes of the atmosphere, and of sun shine and rain, in producing and maintaining that action, both above and in the ground, that is to be attributed the extraordinary results attending the application of bone dust."

The writer then proceeds to say, that a portable manure may be prepared, very easily, and at little expense, in every farm yard, which shall contain the elements which enrich and stimulate the soil to the highest pitch of fertility. The ingredients he recommends, and the proportions of each, are as follows:—1 ton of turf or peat dust, (if ashes the better,) 1 cwt. soot, 1 cwt. common salt, 1 cwt. quicklime reduced to powder, 14 lbs. East-India salt-petre, (nitrate of potash.) The ashes, soot and lime to be well mixed together. The salt and salt petre to be dissolved in urine, as it may be required to saturate and keep moist the heap. After the salts are expended, the urine to be continued—and new ashes to be spread on the top to intercept the vapors. Such a composition, he says, can be formed for 20s. a ton, which would be more efficacious than 40 bushels bone dust, costing 60s. or fifteen cords of yard dung, and might be transported at a single load. The ingredients in the mass supply all the elements for which decayed vegetable and animal substances are used, such as alkali and carbon—as recommended by Arthur Young, and also by Sir John Sinclair.

> "The turf-dust, or ashes, contain carbonaceous matter, in a fit state to combine and retain the active properties of the other ingredients; and serve as a receptacle for the performance of the chemical action of the conflicting substances, until the whole mass becomes impregnated with elastic juices of various kinds, in a highly concentrated state, which are given out gradually, when applied to the soil, according to the influence of the atmosphere, and of sun and rain.—The lime imparts the calcareous property essential to all soils in various combinations with acids. The salt and salt petre yield the mineral and vegetable alkalies, united to nitric and muriatic acid, both of which exert a most powerful influence when separated from their bases—which the contact of caustic lime slowly but certainly effects. The urine, *of all sorts*, furnishes animal matter and ammonia in abundance. The soot adds much strength to the carbonaceous matter, and increases the ammonia. I think this preparation may justly be termed *Imperial Compost.*"

We give the preceding facts, not so much in the expectation that they are likely to result in great immediate benefit to American husbandry, but under the strong belief that they will ultimately prove highly beneficial, by directing the attention of scientific men to that all important branch of national economy—the improvement of the soil. Science and agriculture have hitherto been strangers, although capable of rendering the greatest mutual benefits. We wish to bring them together, and to associate their labors, for the benefit of our country, and the human family. If Dr. Olcott's "*Patent Restorative*," which is noticed in another column, possesses any thing like the properties ascribed to it, and of this we hope to be able to judge, and the cost is not too great, and in this matter we are not advised, it will prove a concentrated or portable manure, of immense value, and will justly entitle the discoverer to the gratitude of his countrymen and of the world.

The American Farmer,

The pioneer agricultural journal of our country, has been resuscitated, by its original editor, John S. Skinner, Esq. who has just issued the first number of a new series at Baltimore. Mr. Skinner rendered his country an invaluable service, in the thirteen volumes of the first series which he published; and he has both the talent and disposition to enhance the obligation by a further devotion of his time to the great work of rural improvement. May he receive, as he merits, a bountiful reward.

Common Schools in Virginia.

"I will infuse good habits and principles into children; for "in twenty short years these children will be the men, giv-"ing the tone and manners of the nation."—*M. Fellenburgh, of the Hoffwyl agricultural school.*

Virginia seems disposed to bend the *twig* as the *tree* should be inclined. She has created a literary fund, not to instruct in Greek and Latin, but to supply English books to her primary schools, and she has chosen a competent board to select *proper* books, and to contract for and supply the schools with the same. The adage teaches, that a man is judged by the company he keeps. It will hold no less true, that a boy may be judged by the books he reads. Books are among a youth's earliest companions, and they have an influence in after life, for better or for worse, upon his habits and morals. The legislature of Virginia have therefore acted wisely, in providing the best companions for their youth, as the surest way of having them brought up in the way they should go.

Had our legislature been equally wise, and had they possessed the moral courage to do a good act in despite of party discipline, they would have done as Massachusetts and Virginia have done—they would have *selected companions for our youth—the books of our common school libraries*—which are to influence their modes of thinking and acting, and which will, in a great many cases, unquestionably, have a controlling influence over their future lives.

The president and directors of the Virginia Literary Fund, have advertised for proposals for the compilation or selection, or either, of a series of books for the use of primary schools—"books adapted to the institutions and habits of the people of that state, which will lay a solid foundation for a sound English education, and at the same time inculcate the purest principles of morality and religion, a true love of country and industrious habits, and direct the attention to the useful arts and common occupations of life."

Virginia, like a prudent parent, lays out the money *for* her children. New-York, like the weak or prodigal parent, gives the money *to* her children, to expend as they list, in bread, or in pea-nuts and powder-crackers.

Buckwheat Straw.

The editor of the Yankee Farmer ascribes great value to buckwheat straw, duly protected from the vicissitudes of the weather, as a food for cattle, and especially for milch cows; and adds, that if cut and boiled, it makes most excellent slop for them. We are apt in our zeal to subserve the interests of our agricultural readers to overrate the advantages of every thing new. The nutrient properties of the stems of all grains and grasses, are believed to be somewhat in proportion to the number of their joints, in which these nutrient properties are principally secreted, and the care with which they have been preserved. Our buckwheat straw, after a frequent long exposure in the field, has been thrown into large piles, where it has been suffered to heat and spoil, as any other forage would heat and spoil under like treatment, and has consequently been considered worthless for cattle feed. More careful farmers have preserved it as they would their hay, and have found it, if not as nutritious, at least worth preserving as cattle forage. That buckwheat straw, properly cured, abounds in nutrient matter, is evidenced by the fact, that when ploughed in green, it affords an excellent pabulum for crops; yet buckwheat straw is not, under any management, as nutritious as corn stalks, and many of the grasses, for farm stock, if the latter are properly preserved. It has fewer joints, and less of nutrient matter, than the stems of most other grains or grasses, gathered, like it, while the stems are green and succulent. Corn stalks are probably twice as valuable, if cut up while they are full of saccharine juice, when the grain is well glazed, carefully and well housed, cut and judiciously fed to stock. But the practice too generally prevails in the east, of spoiling them, by long exposure to the weather, as we are wont to spoil our buckwheat straw. The fiorin, a short jointed grass, is found to be nearly as nutritious when gathered in November, as when gathered in August; but it is not to undergo a wasting fermentation in mass, like our buckwheat straw, nor severed from its roots, to be blanched in the field by the vicissitudes of weather, like the stalks of topped corn. And even that pest, the *quack grass*, first cousin to the fiorin, is probably one of the most nutritious grasses, roots as well as tops, that we have, if properly dried and preserved. Another article, which we consider of little value, and which really is worth very little in the common mode of managing it, might be rendered of as much service for cattle food as buckwheat straw—and that is the stems of our clover, from which we save the seed. And even the first crop of clover, which we cut for forage, is twice as valuable when cured in grass cocks, as it is when made in the old way of spreading to the sun, by which the foliage is wasted, and the stems blanched, before it is fit to be taken to the barn. Every vegetable production of the farm is, in a measure, rendered valuable or worthless, according to the care and judgment we bestow in preparing it for use.

Green Corn Stalks for Fodder.

Where soiling, that is, feeding with cut green food in summer, forms any part of farm economy, we doubt not that corn, sown broadcast for this purpose, may be made to form a very profitable crop, either as a main dependance, or as auxiliary to short or spare pasture. It gives the greatest burthen of green food, and of as nutrient a quality as clover, though it can hardly be made to yield a cutting before August. It might well come in after clover, as food for cows and pigs.

Mr. Holt, of East Haddam, Ct. has made some experiments in raising corn in this way for soiling; and he has found that sixteen square rods of ground, sown with gourd-seed corn, the 12th June, gave food and subsistence for a horse fifty days, and thirty-three days for a cow. An acre would in this way, he thinks, feed thirty cows for a month. A small patch could not fail to be serviceable on any dairy farm, to supply the deficiency of pasture in August and September.

Herefordshire Cattle.

In our account of the most valuable breeds of cattle, in our first volume, we spoke of the Herefords as a branch of the original North Devon stock. By the judicious efforts of some of the English breeders, the Hereford stock is coming into high repute, for their fattening and working properties. As working cattle, they unite the activity of the North Devons, with the size and strength of the Long-Horns. In fattening properties, they have become competitors with the improved Short-Horns. At the autumnal Smithfield show, the Herefords carried five out of seven of the principal prizes, the Short-Horns one and the Devons one. The Hereford cattle have generally white faces, throats and bellies, are of a dark red, and sometimes brown or brindled.

The Herefordshire stock of one of the English breeders, J. D. Kidward, of Westhide, was lately sold at auction, at prices which sufficiently indicate the high estimation in which they were held. A cow sold for £80, ($355;) a heifer and calf for £81; a calf ten days old for £79; a yearling bull calf at £80, &c. and the cows averaged over £30, or $133. These prices, we believe, are about as high as those for which the improved Short-Horns ordinarily sell; though individuals of the latter have often sold at prices much higher.

Use of Sulphur in preserving Plants from Insects.

The Domestic Encyclopædia directs, to tie up some sulphur in a piece of muslin or fine linen, and with this dust the leaves of young shoots of plants; or the sulphur may be thrown upon them by means of a common swan's-down puff, or even a dredging box. No insects or worms will prey upon vegetables which are thus protected. Sulphur has also been found to promote the health of plants on which it is sprinkled.

In support of the recommendation, we state two ca ses wherein we have found the benefit of sulphur, one in protecting plants against insects, and the other in protecting them against mildew. Dusted upon grapes, in the grape house, they have prevented mildew upon the fruit. It is equally efficacious in the open ground, till the sulphur is washed or blown off. For many years, we have lost most of our early cabbages by a maggot which preyed upon the stem under ground.—By mixing sulphur with the grout in which the roots of the plants are dipped before planting, the evil has been wholly prevented; and if the plants are plunged deep in the grout, so as to coat the base of the leaf stems, they are protected from the grub. If scattered upon the rows of young cabbages and radishes, before or after they are up, it would probably be efficacious in protecting both the tops and bottoms.

Industry

Is the grand antagonist of crime, as well as of poverty. *It is the salt which preserves from moral corruption.* Were industry duly and universally inculcated in youth, and enlightened, encouraged and honored, we should have much less need of jails and poor-houses, and we opine, of lawyers, than we have now—three items of expense that consume much of our substance. The late Bishop Asbury, having, in one of his sermons offered a bitter reproof to those who neglect the duty to their children, of bringing them up in moral and industrious habits, suddenly paused and said, "but you will say this is hard. Alas?" he added, letting his voice fall to a low and soft key, "it is harder to be damned." And, temporally speaking, it is harder to see them in the jail or poor-house, or vagabonds at large.

The Multicaulis Fever

Does not seem to have passed its crisis. If aught were wanting to increase it, it is furnished by a late visit from Mr. Olmsted, of East-Hartford, Ct. who exhibited to us forty hanks of beautiful sewing silk, of various colors, weighing between four and five pounds, made from plants of the multicaulis, growing on one-sixteenth of an acre of land, and *the plants themselves put in the ground after the 15th of May, the same season.* So says Mr. Olmsted, and we have no reason to distrust his word. Mr. Olmsted's plan, and we believe his practice, is, to cultivate the multicaulis *as an annual,* that is, to plough up the roots every fall, preserve them in cellars or elsewhere during the winter, and to replant the roots and the cuttings, with the plough, in the spring. Mr. Olmsted also showed various silk fabrics, manufactured at Northampton and elsewhere, and silk in various modes of preparation.

Agriculture of Maine.

We are presented, in the Maine Farmer, with an annual and a semi-annual report of the trustees of the Kennebec County Agricultural Society, containing matters of interest to farmers in every section of the country.

The attention of a considerable portion of the inhabitants of Maine has been taken up with lumbering and fishing; and if agriculture has constituted the great employment, it has not received that attention there till lately which its importance every where demands.—Lumbering and fishing districts afford comparatively poor farmers, however bountiful nature may have been in her gifts to the soil. Within a few years, however, a new interest seems to have been awakened in this matter, and active and successful measures adopted, to advance agricultural improvement. Two agricultural papers have been established, and the state has made liberal appropriations to stimulate and reward her husbandmen; and societies have been formed, and conducted with intelligence and spirit; and improvement has progressed with a pace not perhaps surpassed in any of the other states. One of the leading agricultural societies is that of Kennebec, from which the two reports now under consideration have emanated, and from which we propose to glean some facts and suggestions of general interest.

The public benefits resulting from agricultural societies, are declared, and very correctly, to be palpable, great and certain.

> "These trifling investments, (says one of these reports, in reference to the contributions to the funds of the society,) have yielded a profit not only to the individuals who have made them, nor the agricultural interest alone, but to the country at large, to the whole community. We assert with confidence, that the dollars which have been paid into the treasury of this society, have been refunded to those who have paid them, with interest; and, not like any other appropriations of money, profitable only to those who make them, they have yielded an equal profit to their neighbors; every individual within the sphere of the influence of the society has received, in some shape, a greater or less dividend of the increase."

The Grain Worm.—The report suggests no mode of preventing its ravages, except that of sowing spring wheat late. This coincides with our observations.—All wheat sown in April, or the early part of May, is liable to its attacks; while that sown after the 12th of May, and particularly after the 20th, is likely to escape its ravages. The fly which produces the worm, appeared in Maine last year, on the 27th June, and "closed the campaign about the 19th July—thus remaining about 22 days, during which early sown wheat is in blossom, but the late sown grain does not develop its heads, or but partially." The objection to late sowing is its liability to rust and mildew. To avoid these, the report recommends plenty of seed, and but light manuring. We deem it far better to apply long manure to the previous crop, which may be corn or roots, than to give *any* manure directly to the wheat crop.

Wheat and barley are sown together, for bread-corn, in the proportion of two parts of wheat to one of barley, with decided advantage. The product is said to be greatly increased, the bread good, and the rust and mildew avoided. The culture of barley is also recommended as affording an excellent substitute, when hulled, for rice. The cultivation of this grain is increasing, as an article of food for man and brute.—The committee recommend late sowing, from the 20th May to the 1st June.

Ruta baga is said to be grown on moist as well as on dry soils—on clay loam as well as on sand.

Alternating crops is strongly enforced, in the injunction, to let no grounds that are tillable, remain more than two years in meadow; and that frequent ploughings be practised, whether the object be immediate profit or permanent advantage to the soil.

> "Instances can be referred to," says the report, "where there is a difference in the tilled crop of more than one-half in favor of land which has been but two years in grass, in the same kind of soil, ploughed, manured and managed in the same manner with that which has lain in grass six or seven years."

The committee express an erroneous opinion, we think, when they ascribe to arable or ploughed crops, a fertilizing influence upon the soil. The two years' grass ley gives the elements of fertility; pulverization of the soil, by rendering it open to the influence of air, dew and heat, adds something to these elements, and tends to convert insoluble into soluble geine; but the crop, if carried off, is unquestionably exhausting; and if the process of cropping is continued, without the application of vegetable and animal manures, sterility must be the inevitable consequence. Grain crops are decidedly more exhausting than grass, or root, or green crops.

The reclaiming of bogs and marshy grounds, is strongly recommended; and the example of Massachusetts, where grounds before wholly unproductive, have been made to yield a hundred dollars worth of hay per annum, is given in illustration of the benefits of this kind of improvement. There are within five miles of Winthrop, says the report, bog land enough to produce, if properly reclaimed, five thousand tons of hay annually. This branch of improvement, in connection with draining, even upon uplands, when required, is one of the first importance, not only to agriculture, but to the health of a country. But the subject of draining has not yet sufficiently engaged our attention, and we do not see it noticed in either of the reports.

In a late tour through N. Jersey, and upon the Delaware border of Pennsylvania, we saw an ample field for this kind of improvement. In many places the grounds are flat and wet; the soil of course cold, and the crops meagre. We have no sort of doubt, but that in most cases a thorough Scotch system of under-draining, in connexion with clover, plaster and a judicious alternation of crops, would in five years not only remunerate for the outlay, but would quadruple the agricultural products, and the intrinsic value of the lands. We were happy to learn, that some spirited intelligent farmers had commenced this system of improvement; and wherever it met our observation, the effects fully verified our calculations. We hope the inhabitants of those districts will profit by the example of these pioneers in improvement. In the southern part of our Union, irrigation may affect more than draining. But in the north, we have often a superabundance of water, not always upon the surface, but within the range of the roots of plants, which is hurtful to healthy vegetation. A soil saturated with water in a wet season, is wet and cold in the spring, and dry and hard in a dry summer. It is impervious to the genial influences of air and heat at all seasons.—When drained, the water does not stagnate, but percolates through the soil, leaving it light and porous; the air and moisture do not become stagnant and deleterious; the soil can be worked in all ordinary seasons of farm labor; the vegetable matter is readily decomposed; the roots of the crops have a healthy range in the search of food; and the crop, if there is food in the soil for its proper development, will be abundant.

The semi-annual report, to which we have hitherto confined our notice, closes with a proposition, to have the agricultural and mechanic interests better represented than heretofore, in their legislative councils; or, at least, for the appointment of an agent to represent the interest of the producing classes, to assist in devising the best modes of advancing the great objects of our labor—to render the state independent and prosperous. * * * "The agriculturists and mechanics need the services of such a man, the members of the legislature need his services, and the committee on agriculture need the services of just such a man."

Agriculture and manufactures the basis of our prosperity. Says the annual report—

> "No nation, or state, or community, ever did, or ever can flourish long, when the productive branches of industry are not fostered and encouraged by the government. They are to the community what life is to the system: they give motion and activity to every limb, and if success in one is paralyzed, the other must languish with it. Let agriculture cease to yield her annual harvest, and the mechanic must leave his workshop to seek for the means of subsistence in the forest, or in the lakes and rivers. Let the manufacturer cease to supply his various machines and fabrics, and agriculture can no longer be successfully carried on. The agriculturist may indeed for a time, retain his flocks and herds, and in a half civilized state, live upon their milk and flesh, [and why not add the grains, the roots, and the fruits of the soil?] and clothe himself in their skins, [and in the cloths of his family fabrication, from the wool and flax of his farm.] Agriculture and manufactures are children of one family, and equally deserving the attention of the parent, [the public?] equally requiring the fostering care of those whose aim it should be to devise measures for the common good."

What is national independence?—The committee answer—

> "We are not independent, till our exports, in the whole, are equal to our imports. We shall not increase in wealth till the balance of trade is in our favor."

True, whether the rule be applied to an individual, a family, a state or a nation. The income must be greater than the outgoes, before the individual, the family, the state, or the nation can say—"We are independent." The last few years have increased the debt of the states one hundred and seventy millions of dollars, and upon this debt we are obliged to remit to Europe, annually, ten millions as interest, and the principal is besides to be paid. However we may laud our prosperity, and revel in our day, we are bringing upon our posterity a load of debt that will make them subservient to foreign powers, or to foreign influence, or that will merge them in anarchy and despotism.

The report very properly recommends increased attention to instructing the farmer and mechanic—who constitute the bulk of our population, in a higher grade of studies, and of bringing up our sons in habits of industry and regular application to business.

> "It is this larger part, this majority, that is to give character to the whole. In devising plans, and adopting measures for the future good of a country, it is to the majority we are to look, not to small portions. If our condition as a community is ever to be greatly improved, the habits of the rising generation are to be looked to for the assurance of that improvement. If those who follow us are to be intelligent, prosperous and happy, and fill their places with honor to themselves and the community, we must look to their early habits for a guarantee. They must be furnished with employment, trained to business. They must be inured to that kind of exercise which nerves the arm, and gives vigor to the mind. To this object we call the attention of all who have her interests at heart, and all who have any thing to do in the direction of affairs."

The committee reiterate their former injunction, "never to mow more than two crops of hay from a field before ploughing it." They superadd to this, a recommendation unsound in theory, and which will prove fallacious in practice, "to turn out to pasture all our upland that we are not able to keep under the plough, and depend entirely on straw, fresh meadow hay, grain and roots for keeping stock in winter," or, in other words, to make pasture grounds, which are the only portion of a farm which is improving without the aid of manures, permanent, and thus deprive the farm of all the benefits of the enriching effects of pasture—to confine the alternation of crops to a part, where it is acknowledged to be of great service, instead of extending it to the whole farm. If rotation is beneficial on low grounds, it will be found no less, and we think more so, upon uplands.

Root culture is strongly recommended; and the use of roots, in fattening stock, is deemed far more profitable than fattening upon hay and grain. The committee estimate a profit of $20 the acre under root and other tillage crops, over that of an acre in meadow.

Hint in Transplanting.

The common error in transplanting trees, is not making the holes, or pits, for their reception sufficiently broad and deep. The roots require a mellow soil to strike down and horizontally in; and if the earth under and around them is left undisturbed and hard, they can not extend themselves for food, or but very slowly; the plant consequently grows but slowly, if it survives.—The following experiment, made by M. Chalermeau, illustrates the importance of this hint. The hole should not be proportioned to the extent of the roots *as they are,* but to their extent as they *may be* and *should be.*

> "Four peach trees, resembling each other as to size and vigor of growth, as much as possible, were planted. No. 1 in a hole three feet square; No. 2 in a hole two feet square, and Nos. 3 and 4 in holes eighteen inches square. The soil and exposition similar. No. 1 has every year given the most abundant crops, and the relative sizes of the trees are now as follows: the stem of No. 1, 18 feet high and 8 inches in circumference; that of No. 2, 9 feet high and 5½ inches in circumference; No. 3, 6 feet high and 3 inches 8 lines in circumference; and No. 4, 5½ feet high and 3 inches in circumference."

Showing a difference between No. 1 and No. 4—between large holes and small holes—of five inches in circumference, and 12½ feet in height. Apple, pear and forest trees, generally having a larger spread of roots than the peach, require proportionally larger holes.

Diseases of Neat Cattle.

There have a great number of cattle died in the country, within a few years, of a disease not definitely understood or described, but by many believed to be the *murrain;* and many have also been lost by *hoven,* for want of a knowledge of a proper remedy of relief. The following extracts, from the Encyclopædia of Agriculture, descriptive of the *murrain,* and of kindred diseases,—of the symptoms and treatment of these diseases, and modes of prevention;—and also of the *hove* and the modes of relief—cannot fail of proving interesting to cattle breeders and graziers. We will repeat here an opinion, founded upon reason and long experience, that the best preventive of disease in our farm stock, is the free use of salt, as a condiment; to which our cattle have had daily and free access for fifteen years, during which time no indisposition has appeared among them.

Mild fever, pantas or paretaria. Cattle appear sometimes affected with heat, redness of the nostrils and eyelids; they refuse food, are dull, evacuate stale with difficulty; and the urine is high coloured. These symptoms are often aggravated every other day, giving it the appearance of an intermitting affection. The complaint is often brought on by over driving in very hot weather, occasionally by pushing their fattening process too fast. If there be no appearance of malignancy, and the heaving be considerable, bleed, and give half an ounce of nitre, night and morning; but unless the weather be cold, do not house the animal.

Inflammatory fever, is called, among farriers, cow-leechers, and graziers, by the various names of black-quarter, joint felon, quarter-evil, quarter ill, showing of blood, joint-murrain, striking-in of the blood, &c. Various causes may bring this on. It is sometimes epidemic, and at others it seems occasioned by a sudden change from low to very full keep. Over driving has brought it on. No age is exempt from it, but the young oftener have it than the mature. The inflammatory stage continues but a few days, and shows itself by a dull heavy countenance, red eye and eyelids: the nostrils are also red, and a slight mucus flows from them. The pulse is peculiarly quick; the animal is sometimes stupid, at others watchful; particularly at first, and sometimes irritable. The appetite is usually entirely lost at the end of the second day, and the dung and urine either stop altogether, or the one is hard and the other red. About the third day a critical deposite takes place, which terminates the inflammatory action: and it is to the various parts to which this occurs, that the disease receives its various names. The deposite is, however, sometimes universal, in the form of a bloody suffusion throughout the whole skin. In others, swellings form on the joints, or on the back or belly; and in fact, no part is exempt from their attack. Sometimes the animal swells generally or partially, and the air being diffused under the skin, crackles to the feel. After any of these appearances have come on, the disease assumes a very malignant type, and is highly contagious.

Treatment of inflammatory fever. Before the critical abscesses form, or at the very outset of the disease, bleed liberally, and purge also. Give likewise a fever drink. (1.) If, however, the disease be not attended to in this early stage, carefully abstain from bleeding, or even purging; but instead, throw up clysters of warm water and salt to empty the bowels; give salt mashes. Green meat should be allowed, and a very cool shelter should be provided. As medicine, three doses are necessary, every day, of the malignant epidemic fever drink; (2) and if the weather be warm enough to allow it, two or three hours turning out in the field in a day is proper. It may be added that four drachms of muriatic acid in three pints of oak bark decoction, given twice a day, has proved useful. The swellings themselves may be washed with warm vinegar, both before and after they burst.

Catarrh or influenza in cattle, also known by the name of *felon,* is only a more mild form of the next disease. Even in this mild form it is sometimes epidemic, or prevalent among numbers, or endemical by being local. *Very* stormy wet weather, changing frequently, and greatly also in its temperature, are common causes. We have seen it brought on by change of food from good to bad, and from too close pasturage. It first appears by a defluxion from the nose; the nostrils and eyelids are red; the animal heaves, is tucked up in the flanks, and on the third day he loses the cud. There is a distressing and painful cough, and not unfrequently a sore throat also, in which case the beast almost invariably holds down his head.

The treatment may in some cases be cut very short, by giving, as soon as the attack takes place, *sweet spirits of nitre,* or when not at hand, *spirit of hartshorn,* an ounce, in a pint of sound ale [or other liquid.] After the running has come on, or as soon as the weakness has become considerable, give night and morning the fever drink (1) in a mash or drink. Most mashes, when the weakness is great, are proper. Bleeding only the first two days, carefully sheltering, but in an open airy place, and littering well up.

The malignant epidemic influenza is popularly called the *murrain* or *pest;* and has at various times made terrible havoc among cattle. Ancient history affords ample proof of its long existence; and by accounts handed down, it does not seem to have varied in its type materially. In 1757, it visited Britain, producing extreme fatality among our kine. From 1710 to 1714 it continued to rage on the continent with unabated fury. The years 1730 and 1731, and from 1744 to 1746, witnessed its attack, and produced many written descriptions of it. The British visitation of the malady in 1757, elicited an excellent work from the pen of Dr. Layard, which was afterwards translated into several languages.

Dissections of those that have died of this disease, according to Sauvages, have showen marks of a great inflammation, and of a great putrid tendency; but the solid parts seldom run into gangrene. The fluid secretions, however, always were sufficiently dissolved and broken down by putridity The paunch, he says, was usually filled with undigested matter, and the other stomachs highly inflamed. The gall bladder was also commonly distended with acrid, thick, brown bile. Goelich, who likewise dissected these subjects, describes the gall as particularly profuse and intolerably fœted. According to him, the whole alimentary canal, from the mouth to the anus, was excoriated. Gawnola describes the murrain as accompanied with pustulous sores; and so great was the putrid tendency, that even the milk, before it dried up, which it generally did the fourth day, became putrid.

Symptoms of the murrain. Dr. Layard described it as commencing by a difficulty of swallowing, and itching of the ears, shaking of the head, with excessive weakness and staggering gait; which occasioned a continued desire to lie down. A sanious fœtid discharge invariably appeared from the nostrils, and eyes also. The cough was frequent and urgent. Fever exambating, particularly at night, when it usually produced quickened pulse. There was a constant scouring of green fœtid dung, after the first two days, which tainted everything around: even the breath, perspiration and urine were highly fœtid. Little tumors, or biles, were commonly felt under the skin; and, if about the seventh or ninth day these eruptions became larger, boils and buboes appeared with a lessened discharge of fæces, they proved critical, and the animal often recovered; but if, on the contrary, the scouring continued, and the breath became cold, and the mouth dark in colour, he informs us, mortality followed. Sauvage describes the murrain as showing itself by trembling, cold shivers, nose excoriated with an acrid discharge from it, purging often the first two days, but previous to which there was often costiveness. Great tenderness about the spine and withers was also a characteristic, with emphysema, or a blowing up of the skin by the air discharged underneath it.

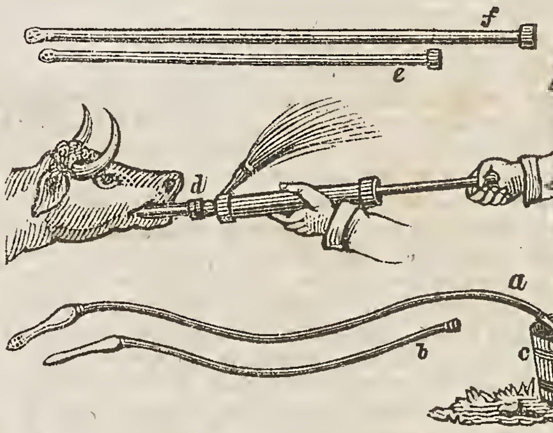
Treatment of the murrain. In the early stages, all eminent authors recommend bleeding; but which should not only be confined to the very early periods, as to the first two days, but also to such subjects as by their previous health and condition can bear it. The animals should be placed in an open airy place; the litter should be frequently removed; and the place itself should be fumigated with the preventive fumigation (3.) It has been recommended to burn green boughs as a substitute; even charcoal fires, occasionally carried round the place, would be useful. Dr. Layard advised the body to be washed with aromatic herbs in water; but vinegar would have been better. In early stages, saline purgatives, as from ten to twenty ounces of Epsom salts, are to be invariably used. If the scourings have already come on, still, however, purge, but with only half the quantity; an artificial purge will carry off the morbid bile; and if excessive weakness do not come on, the same may be advantageously repeated. Setons are also recommended in the dewlap. When abscesses appear, they may be opened, and their contents discharged, washing the wound with brandy or vinegar, if putrid sloughing takes place. The emphysematous swellings, or cracklings, may also be opened, and the air discharged. The other essentials of medical treatment, as detailed for the preceding disease, is here applicable in every particular. When recovery takes place, it is usually a very slow process, and requires care to prevent other diseases supervening. The animals should continue to be housed, and neither exposed to sun or wind for some time, and the feeding should be nutritious.

The prevention of the murrain, or the prevention of its spreading, in many respects is even more important than its medical treatment. When it has already appeared, all the out buildings, but particularly the ox lodges or stalls, should be daily fumigated with the preventive fumigation (3); and even the whole of the infected districts should have frequent fires of green wood made in the open air, and every such district should be put under a rigorous quarantine. The cattle on every farm should be examined three or four times every day, and the moment one is found to droop, he should be removed to a distance from any of the others. In very bad weather, while the disease is prevalent, the healthy cattle should be housed, and well fed; and their pasture should also be changed. The bodies of those which die of the disease should be buried with their skins on, very deep in the earth, and quick-lime should be strewed over them.

The hove or blown in cattle is also an inflammatory affection of the paunch, ending in paralysis and rupture of its substance. From the frequency of its occurrence, it has become a subject of investigation with almost every rational grazier, and a particular matter of inquiry with every agricultural body; from whence it is now very successfully treated by the usual attendants on cattle, when skilful; but when otherwise, it usually proves fatal. It is observed to be more frequent in warm weather, and when the grass is wet. When either oxen, cows or sheep, meet with any food they are particularly fond of, or of which they have been long deprived, as potatoes, turnips, or the different grasses, particularly red clover, they eat greedily, and forget to lie down to ruminate, by which means the first stomach, or paunch, becomes so extended as to be incapable of expelling its contents. From this inflammation follows, and fermentation begins to take place: a large quantity of air is let loose, which still adds to the distention, till the stomach either bursts, or, by its pressure on the diaphragm, the animal is suffocated. The situation of the beast is known by the uneasiness and general swelling of the abdomen; while the circumstances of the animal being found with such food, or the presumption that it has met with it.

Treatment. There are three modes of relieving the complaint, which may be adverted to according to the degree of distention, and length of time it has existed. These are, internal medicines; the introduction of a *probang,* of some kind, into the paunch by the throat; and the puncturing it by the sides. Dr. Whyatt, of Edinburgh, is said to have cured eighteen out of twenty hoved cows, by giving a pint of gin to each. Oil, by condensing the air, has been successfully tried. Any other substances, also, that has a strong power of absorbing air, may be advantageously given. Common salt and water, made strongly saline, is a usual country remedy. New milk, with a proportion of tar equal to one-sixth of the milk, is highly spoken of. A strong solution of prepared ammonia in water often brings off a great quantity of air, and relieves the animal. [Common lye, procured either by pouring water upon ashes, or dissolving pot or pearl ashes, has proved highly efficacious.] Any of these internal remedies may be made use of when the hoven has recently taken place, and is not in a violent degree. But when otherwise, the introduction of an instrument is proper, and is now very generally resorted to. The one principally in use is a species of probang, invented by Dr. Monro, of Edinburgh. Another, consisting of a cane six feet in length, and of considerable diameter, having a bulbous knob of wood, has been invented by Eager, which is a more simple machine, but hardly so efficacious. It is probable that in case of emergency, even the large end of a common cart whip, dexterously used, might answer the end. But by far the best instrument for relieving hoven cattle, as well as for clistering them, is Read's enema apparatus, which is alike applicable to horses, cattle and dogs. It consists of a syringe (*a*, *Fig.* 19,) to which tubes of different kinds are applied, according to the purpose, and the kind of amimal to be operated upon.

[Fig. No. 19.]



There is a long flexible tube for giving an anema to horses and cattle (*a*) and a smaller one for dogs (*b*). To relieve hoven bullocks effectually, it is necessary not only to free the stomach from an accumulation of gas, but from the fermentating pultaceous mixture which generates it. For this purpose a tube (*f*) is applied to the extremity of the syringe, and then passed into the animal's stomach through the mouth, (*d*) and being put in action, the offending matter is discharged by a side opening. When the same operation is performed on sheep, a smaller tube (*e*) is made use of. The characteristic excellency of Read's instrument is, that there is no limit to the quantity of fluid that may be injected or extracted. The same instrument is used for extracting poison from the stomach of man, for smoking insects, extinguishing fires and syringing fruit trees. [This machine is now sold at the seed shops, as a garden syringe—lacking merely the tubes which may be prepared readily to screw on.] The introduction of any of these instruments may be effected by the aid of an assistant, who should hold the horn of the animal by one hand, and the dividing cartilages of the nose in the other; while the operator himself, taking the tongue in his left hand, employs his right in skilfully and carefullly introducing the instrument; the assistant bringing the neck and head into such an attitude as to make the passage nearly straight, which will greatly facilitate the operation. But when no instruments can be procured, or as cases may indeed occur when it is advisable not to try them, as when the disease has existed a considerable time; or the animal has become outrageous, or the stomach so much distended with air, that there is danger of immediate suffocation or bursting—in these instances the puncture of the maw must be instantly performed, which is called *paunching.* This may be done with the greatest ease, midway between the ilium, or haunch bone, and the last rib of the left side, to which the paunch inclines. A sharp pen-knife is frequently used; and persons in veterinary practice should always keep a long trochar, which will be found much the most efficacious, and by far the most safe, as it permits the air to escape certainly and quickly, at the same time that it prevents its entrance into the cavity of the abdomen, which would occasion an equal distention. As soon as the air is perfectly evacuated, and the paunch resumes its office, the trochar may be removed; and, in whatever way it is done, the wound should be carefully closed with sticking plaster or other adhesive matter. It is necessary to observe that this operation is so safe, that whenever a medical assistant cannot be obtained, no person should hesitate a moment about doing it himself. After relief has been afforded either by the probang or the paunching, a stimulant drink may yet be very properly given, such as half a pint of common gin, or one ounce of spirits of hartshorn diluted in ale or water, or 2 oz. of spirits of turpentine in ale, may any of them be used as an assistant stimulus. When also the cud is again chewed, still some relaxation of the digestive organs may remain; at first, therefore, feed sparingly, and give, for a few mornings, a tonic (4).

(1.) *Fever drink*—Sweet spirits of nitre 1 ounce, mindererus spirit 6 ounces, water 4 ounces.

(2.) *Malignant epidemic fever drink*—simple oxymel [a mixture of vinegar and honey] mindererus spirit, beer yeast of each 4oz. sweet spirits of nitre 1oz.

(3.) *Fumigations for purifying infected stables, sheds, &c.*—Manganese 2 ounces, common salt 2 ounces, oil of vitriol 3 ounces, water 1 ounce. Put the mixed manganese and salt into a basin; then, having before mixed the vitriol and water very gradually, pour them, by means of tongues, or any thing that would enable you to stand at a sufficient distance, on the articles in the basin gradually. As soon as the fumes rise, retire and shut up the door close.*

(4.) *Tonic Alteratives*—Gentian, aloes, ginger, blue vitriol, in powder, of each one drachm, oak bark in powder 6 drachms.

Spirit of Foreign Agricultural Journals.

The *principles* of an enlightened agriculture have almost a universal application. The *practices* of agriculture vary with climate, with soil, and the demands of the market. The European agricultural publications contain much of the principles that is useful in our practice, and much in practice, from which we may profit. They also contain much which is very useful on the other side of the Atlantic, but which it would be a waste of ink and paper, to promulgate here. We design to separate the wheat from the chaff, that is, to give an abstract, or to publish in detail, such matters, as have a direct application to our husbandry, whether in principle or in practice, and to omit what is inapplicable to our climate, our products and our markets. These notices will of course be excursive, as we find them in perusing the foreign works to which we have access.

If any apology or explanation is deemed necessary, for filling so many of our columns with *foreign* instead of *domestic* extracts—we have two reasons to offer, viz. 1. That the principles or science of agriculture are better understood and applied in Europe than they are in America, and the practices, perhaps from necessity, more economically and profitably managed there, than they are with us. And 2. Because these extracts add much to the stock of our agricultural knowledge, by superadding to American skill and knowledge, which is being widely disseminated, the agricultural skill and knowledge of another continent, from whose science and practice we have profited greatly, and may profit much more, in all the arts of productive labor, and particularly in the various departments of husbandry. In selecting models for imitation and improvement, it is always wise to select good ones; for if we fail in copying the entire picture, we may catch at least the great outlines, and fill up the canvass as our leisure or our interests will permit or require.

HONEY-DEW AND MILDEW PREVENTED BY SALT.

George W. Johnson has given an essay, in the Quarterly Journal of Agriculture, on the diseases incidental to the most usually cultivated plants, in which he ascribes the honey-dew to a morbid state of the sap of the plants on which it is found; and he states several experiments in which it was prevented, by the application of a weak solution of common salt. There is danger in making the pickle too strong, so as to injure the plant. Put one ounce of salt, says Mr. Johnson, to a gallon of water. "I have noticed," says he, "that standard fruit trees, around which, at the distance of six or eight inches from the stem, I had deposited, at the depth of twelve inches, a quantity of salt, to promote the general health of the tree, according to the manner adopted to some extent in the cider countries, for the apple orchards; that these escaped the honey-dew, (which infested adjacent trees,) just as well as those which had been watered with salt and water."

The experiments of Hitt and Knight, which Mr. Johnson quotes, go to show, that salt is also a preventive of mildew, a conclusion which we had almost arrived at, from our limited experiments upon the gooseberry and grape. By the use of water in which a small portion of common salt had been dissolved, Knight preserved the health of his autumnal crop of peas from mildew, a disease to which they are very subject. "It is more than probable," says this distinguished horticulturist, "that most of the diseases of plants arise, in some way or other, from the irregular action of the sap, caused very often by sudden transitions in the atmosphere.—By a very easy experiment, the cultivator may convince himself of the power of common salt in preventing these injuries."

The use of salt in promoting health, or preventing disease in animals, is now well known; as is the fact, that it is most favorable to farm stock when given daily. How far the analogy will hold good between animals and vegetables, remains to be ascertained. It seems from the experiments above noted, that it does operate beneficially in preventing certain diseases in some plants. This should encourage us to experiment with it upon others.

In speaking of the *extravasation of sap* from trees and vines, which often takes place to a prejudicial extent, from wounds in trees caused by winter or spring pruning, before the leaves have expanded, Mr. Johnson directs, as the best means of preventing or checking the flow, that the wound be covered with a sponge, dipped in a solution of sulphate of iron, and the sponge covered with a piece of sheet lead, and bound there firmly.

AGRICULTURAL SCHOOLS,

Are springing up in Ireland, and measures are taking to establish them in England; while in France, says the Westford Independent, "new schools are founded daily, establishments for rearing cattle of improved breeds, and making experiments in husbandry, are formed and conducted at the cost of government, and a considerable number of our best animals and sheep, are constantly purchased to improve the native stock. Professors are appointed in various parts of the country, to give lectures on agriculture, and in short, all possible means taken to render the nation independent of foreign countries, for the supply of such necessaries of life as are capable of being produced by their own soil. We consider these schools the grand basis of agricultural improvement—the light that will shed its benign influence on the mist that now envelops the principles upon which the most important practical operations in agriculture are based."

The most prominent plan proposed in England, is to establish a national agricultural college, upon a broad and liberal basis, to be supplied with the best teachers, and to connect with it pattern or experimental farms, upon different soils, and in different sections of the kingdom, to be under the direction of the best practical men. In the college the scientific theory of the art is to be taught, and the explanations of the different systems of practice in the kingdom and abroad to be given.—The practical instructions to be given on the farms, to which the students are to be sent for stated periods.

"These farms to be used solely for experiments, to test and prove every suggestion that science, theory and practice may offer: and if upon repeated trials, they be found irreducible to practice, they will fall to the ground; if they succeed, they would be sent forth as attested and valuable facts. The members of the central college and the conductors of the farms would be in constant communication, comparing and examining every suggestion and observation, both by science and practice, and detailing to each other, for the general benefit, the results of reflection and experience." "If ever such an institution be established," says a writer in the Farmers' Magazine, "the first step must be, to kick sheer overboard, the prejudices of men, and to level with the dust that curse of the human race, the great barrier to improvement in all ages of the world. On every subject, the greater part of mankind are biassed in favor of some particular way of thinking, and way of performing any operation which they have adopted, and to which they have been accustomed, and of which very few are ever able to divest themselves. Prejudice completely obscures our perceptive and intuitive powers, clogs our understanding, and perverts our judgment, and renders wholly useless the reasoning faculty conferred upon us as the distinguishing characteristic of our nature. No sound judgment can be exercised on any subject, or a satisfactory conclusion arrived at, where this pernicious propensity prevails: no dependence can be placed on the opinion of any man, who allows his judgment to take precedence of his reason, and whose mind is wilfully shut against conviction.—For the furtherance of any art, the great essential desideratum is to combine theory and practice; and on this point the agricultural world (with some splendid exceptions,) has floundered over head and ears in the mud. It is only of late years, that our mechanics and manufacturers have been able to combine them; but until that be effected, and as much as possible in the same persons, or by different persons being in constant and friendly intercourse, it is very evident the progress will be slow. If properly established and conducted, incalculable benefits might accrue. The members of the college must consist of men eminent for knowledge in every branch of education connected with agriculture, and one thoroughly versed in agriculture itself, and their employment would be to draw suggestions from the investigations of science, to be transmitted to the farms for the test of experience. The conductors of these farms must be the most intelligent practitioners that can be found for the soils they are intended to manage; thoroughly acquainted with arable farming and the suitable implements; our different breeds of stock; intelligent and open to, and able to comprehend, and able to execute, the suggestions transmitted to them from the central college. Until we have a field of tests, we do not know what invaluable discoveries may be hid in suggestions laughed at and neglected, or in those that may be made. That great absurdity has attended many of them, must be readily granted; but the wheat cannot be obtained without separating it from the chaff."

Thus far our extract. There is no truth more palpable, than that science, to benefit agriculture as it has benefitted the other arts, must be associated and combined with its practical labors, as it has been profitably combined with the labors of the artizan and manufacturer. And we are of opinion that this would be more efficiently done, in a school and farm in the same location, than it could be where the school is located in one place and the farm in another. Locations may be found which combine most of the varieties of soil; and the principles of science being well inculcated, and their general application to practice properly taught and explained, the pupil would be qualified judiciously to vary his practice according to soil and circumstances. Like civil engineering, which was hardly taught or practised before the commencement of our system of internal improvements, a school of scientific and practical agriculture would soon produce competent teachers, to take charge of new institutions, or to disseminate in the community, the various branches of useful knowledge acquired in the school.

STRATHMORE AGRICULTURE.

A premium of ten sovereigns was awarded last fall, by the Highland Agricultural Society, to Robert P. Newton, of Hallyburton, for an essay on the rural management of the Forfarshire part of the western district of Strathmore. We abstract some facts of general application, as interesting and profitable to our readers.

The potato, Hopetoun and common oat, are cultivated extensively, not only as cattle food, but as a principal bread corn for the inhabitants. The common oat pays best on poor soils; the Hopetoun ripens earliest, an object there, but is most liable to smut; it gives the best straw, and the potato oat, on good land, the best yield in grain.

Root crops, that is, the potato and ruta baga, are extensively cultivated, fed to cattle, and, being thus converted into beef and mutton, are conveyed, at trifling expense, to market, and turned into money, while the manure they produce, goes to enrich the land.

Bone dust is in high estimation, and a handsome public acknowledgment has been made to Mr. Keillor, who first introduced it, and demonstrated its advantages. Bone dust and *sheeping* together, that is, pasturing of sheep, form the most ample and rich preparation for the barley crop, which is a favorite one in the district. It would be equally advantageous for any other arable crop, which should follow turnips.

REARING CALVES.

We have endeavored to convince our breeders, and even our dairymen, that they mistake their interest, in not rearing more calves. Cattle have become scarce, from the demands of the butcher and the dairyman, and command double the price which they formerly did. It has been the practice of the dairymen to *deacon* their calves, that is, to kill them at three days old, to save milk; and of the breeder of prime stock, to give two cows to one calf, in order to grow *large* calves—a bad criterion, however, of *good* ones—to let the calves run with the cows, and thus sensibly to diminish the value of the cows as good milkers. In Strathmore, a far better mode is practised. *One* cow brings up *five* calves, and instead of the latter subsisting altogether upon milk, they are early taught to subsist, in part, upon that food which is ultimately to constitute their entire subsistence. This course is dictated as well by economy as by nature. This mode of managing calves is from Mr. Watson, and we give it in his words.

"The cows intended for nursing, generally calve early in the season, about the month of January or February, when a strange calf is procured from some of the small tenants in the district, who have dairies. This calf is suckled with the others by the same cow, and although the cow at first shows great dislike to the stranger, in a few days she receives it very quietly, care being taken that both are put to suck (one on each side,) exactly at the same time, by tying the calves bands to the stall, or to the band of the cow, so as to keep each calf at its own side. They remain with the cow for fifteen or twenty minutes, by which time her milk is perfectly drawn away. As the calves advance in age, they eat hay, sliced potato, porridge, and other food they are inclined to take.—By the first of May, or as soon as grass is ready, they are weaned and turned out from the byre, when two fresh calves are immediately put into their stalls, and receive the same treatment, excepting that they are turned out at twelve o'clock, after they have got their suck, to eat grass, and are brought into the byre again at evening, when the cows come in to be sucked. This set is ready to be weaned by the first of August, and a single calf is put into the feeding-pen, and fattened for the butcher, the season being now too late for rearing. As these are fed off, the cows are let off milk, having each suckled *five calves*. It is necessary to have a very steady and careful person to attend to the suckling, which has to be done three times a day, viz: early in the morning, before the cows are turned out to grass, at mid-day, and in the evening when the cows come into the byre for the night, and get a little cut grass, tares, or other green food. The byre is arranged so that each of the cows has a stall about four feet wide, with their heads to the wall; and on the opposite wall the calves are tied up, two in a stall, exactly behind the cow, so that there is little trouble in putting them to the cow, and no chance of misplacing them. The fat calves have in some seasons been sold at £5 (=$22,) each, this being the scarcest time of the year for veal."

On the advantages of sheep husbandry, in improving the soil, Mr. Newton is decided and earnest.

"It is now universally allowed," he remarks, "that there is no manure which diffuses itself more equally, or which is more valuable in its effects, than that produced by sheep, whether as applied on pasture land or in turnip feeding on the ground. Farmers in this district are now so satisfied of this, that they almost universally make a point of grazing their pasture lands one year with sheep. It is an old remark, that where you have plenty of sheep, plenty of *oats* follow."—Oats, it will be remembered, being the great agricultural staple of Scotland.

In speaking of the roads, Mr. N. very justly gives a preference to M'Adams over rail roads, as means of facilitating agricultural improvement and profit. "The superiority of the M'Adams system," he says, "is now almost universally acknowledged, and almost universally adopted." Rail-roads are private, or corporate property, subject to the caprice and changes of their proprietors; while the other roads are public, upon which every man can travel with his own team, subject to a moderate regulated toll.

Cattle sheds are general. The pillars which support the roof are of cast iron, and cost 10s. ($2.22,) each, the walls are of stone, and the roof is slated. The cattle are put in them in cold, rainy or stormy weather, and well littered. These sheds are cleaned out at the middle and close of the season, and the manure is conveyed to some spot for a dung hill, convenient to the field to which it is to be applied; and women and boys are employed to go over the pasture with a barrow, to collect the droppings, which are added to the pile; the dung is turned and mixed, and in August and September, three parts of waste earth are mixed with two of the dung; and in this condition it is soon after applied as a top dressing to grass lands, in proportion to 20 cart loads, of 30 bushels each, to the acre.

The rents in this district average 32s. or about $7 the acre. The "*peasantry*"—farmers—are represented to be a "sober, hard-working quiet race;" the "*hinds*"—

---

* Chloride of soda, or of lime, exposed in a tiquid form, in open vessels, would probably be alike afficacious.

laborers or farm-servants, unless they are married, "are generally huddled together in what they call a *boothy*. Each man has his allowance of meal and milk; and brose [oat-meal with milk or water,] constitutes his breakfast, dinner and supper"!!!

BENEFITS OF DRAINING.

In the "Mark Lane Express," it is stated, that land which, with difficulty, had been let at *five shillings* per acre, became worth two guineas (42s.) to the landlord, by the mere operation of draining. This, says the writer, I know to be the case on many large estates in Scotland. It is mentioned, that an increase of twelve bushels an acre may be counted upon as one result of draining; but I can appeal to the principal agriculturists of East-Lothian and Ayreshire, (the counties where draining is most advanced,) whether the increase of crop consequent upon that process may not more properly be put at *double*, and even *treble*, the previous produce of the land.

CULTURE OF THE POTATO.

Some interesting facts in regard to the culture of the potato, are given in a communication of Mr. Towers, a correspondent of the late Mr. Knight, in the Quarterly Journal of Agriculture. The communication embraces the opinions and experience both of Mr. Towers and Mr. Knight; and no persons are better qualified, perhaps, than these two gentlemen were, both from their knowledge of vegetable physiology and numerous and carefully conducted experiments, to make sound conclusions in the matter.

Potatoes will grow in any soil, containing vegetable matter; but, says Mr. Towers, the produce in amount or quality appears to be materially influenced by local agencies, even in soils of the same constitution; and he cites cases, where a kind is very good in one district, and very inferior when grown in another district.

That soil and routine of culture which produce the strongest haulm, will yield the greatest bulk of tubers; though if the foliage is too massive, the quality of the tubers will be inferior, and prove deficient in starch. He therefore prefers a medium growth of tops, wherein the balance of strength is supported between the stem and the leaves, the result of a well prepared and healthy soil, reciprocating with the stimulus of the sun's rays, and the decomposing agencies of atmospheric air and water. Firmness of texture and mealiness ought to be the standard, rather than weight of tuber; and such, he says, may be produced by proper management, on all soils. Although Mr. Knight has calculated that 1,000 bushels, weighing 80lbs. each, may be produced on an acre, partially demonstrated by experiment, Mr. Towers estimates the average crop of the county at 300 bushels.

Mr. Towers finds fault with the practice of cutting potatoes sometime before they are planted. The starch exudes from the cut surface, and the set becomes soft and flaccid in consequence of emptying the cellular tissue by evaporation. He cuts in the field as he plants.

He quotes a letter from Mr. Knight, saying, that he obtained 670 bushels of 80lbs. each, from an acre; that he always plants whole seed, and selects the largest for seed, and from very early crops; that he plants them upon their ends, to stand with the crown end upwards, at four or six inches apart in the rows, and the rows two to four feet apart, according to the natural growth of the tops, the taller growth requiring the widest intervals —if the height of the stems be three feet, the intervals between the rows should be four feet.

Both of these gentlemen concur in the opinion, that the blossoms take away a great deal of sap, or nutriment; and they therefore prefer those kinds for culture, which do not produce seeds, or balls, of which Mr. Knight obtained several new varieties by cross impregnation. The exhausting influence of blossoms and fruit may be seen upon fruit trees. If a tree fruits abundantly, it makes little or no growth in wood; if one blossoms which has been just before transplanted, it proves injurious or fatal to the tree.

To obtain early potatoes, Mr. Knight takes those which have ripened early, for the reason, that those which ripen late, are not sufficiently "*excitable*," though more eligible for a late, or rather moderately early crop, the produce of which will be proper to plant for a very early crop. Mr. Knight adds, that immature potatoes, or those which have not become perfectly ripe, are as good for planting as others. Mr. Towers' experiment with *early* potatoes, gave an increase of six for one.

Mr. Towers *cuts* his potatoes into sets comprising two, and not more than three eyes. He calls the end where the eyes are chiefly congregated, the *rose*, or *crown;* and he cuts diagonally, dividing the crown into different sets. Two facts are here stated, which, we confess we never before considered, but of the truth of which we are satisfied, and which we believe few farmers have duly appreciated. We state them in Mr. Towers' words.

> "*First*—All the eyes of entire potatoes do not push at one time, therefore it is a mistake to suppose, that a plant becomes crowded by a useless haulm, if the potatoes be planted whole." [We see this at planting. Some eyes have sent forth their sprouts, while others remain perfectly dormant.]
>
> "*Again*—Persons have imagined, that weakness of the root is occasioned by the destructive action of frost upon the earliest shoots. This is also a mistaken notion. For if any eyes remain unexcited in the tuber under ground, the loss of one shoot is speedily supplied by the substitution of another. Time may, indeed, be sacrificed to a certain extent, but that is all. Of this any one may convince himself, by endeavoring to exterminate a straggling potato; he may hoe, or pull off the first shoots, and think his ground cleared of the intruder; but in a week or two the spot will be again occupied, and it will be perceived, that nothing short of the complete removal of the tuber can prove effectual. If sets, with one or two eyes, have been planted, and have sent up all their shoots, then the destruction by frost may prove fatal; but it may happen that a shoot may appear to be killed to the ground, and yet produce a fruitful plant, though late in the season, from embryo eyes seated round the stem, near its point of eruction from the potato."

These gentlemen seem to have arrived at the conclusion, and it is certainly a rational one, that *light*, that is, the influence of solar light upon the plants and soil, has a controuling influence upon the quality and product; and hence they argue, that the foliage should not be crowded, but be duly exposed to the sun and air.

Mr. Towers prefers sets for seed to whole tubers.—He found that sets gave as great a product as whole tubers; generally about six of produce to one of seed, and that by this means he effected a great saving of seed. He also applied lime, ashes or gypsum to his cut potatoes before burying them in the ground, not only to increase their growth, and prevent the waste of their juices, but to prevent their being attacked by the grub. In several experiments he obtained 354lbs. from 12lbs. of seed, 520 from 30lbs. 215 from 22lbs. and 150lbs. from 30lbs. of seed.

The potato, according to Mr. Towers, prefers a free soil; but where the soil is heavy, he advises, that the land be set up in one bout ridges in autumn, to expose a great surface to the frost; that the manure be previously added, with coal ashes if they are to be had, which never fail to meliorate heavy binding earth. He says that the plant affects a light rich soil, wherein its fibrous roots and tuber bearing processes may wander laterally but not deeply; that the manure should be well blended with the earth; and that six inches of good mould is enough for the crop.

The keeping quality of a variety of potatoes is to be judged of by the protrusion of their eyes or shoots in spring, the eyes of the good keepers remaining longest dormant. To keep them in good eating condition, during winter, he advises that they be kept in a dry cave, or pit, or cellar, where the utmost degree of equable cold can be maintained, consistent with the exclusion of frost.

EXHIBITION OF SEEDS.

An exhibition of seed corn and grass seeds is noticed in a late Gardeners' Gazette, at which handsome premiums were awarded for the best parcels. The weight of some of the prize seeds were as follows:—Barley 57 and 58lbs. 3oz. the chevalier the heaviest; oats 45lbs.; rye grass 21lbs. the bushel. Whatever diversity of opinion may prevail, as to the policy of awarding premiums on fat cattle and large crops, none we believe is entertained as to the propriety of encouraging, by premium, the raising and selling of good seeds.

AGRICULTURAL STATISTICS.

In Great-Britain there are 961,154 families, embracing 4,805,670 individuals, which belong to the agricultural class, and a total population of 16,539,318—a proportion of a little more than one agriculturist in four of the population. In Ireland, the agricultural families amount to 884,339, embracing 4,863,864 individuals, in a total population of 7,767,441. The cultivated acres in Great-Britain exceed 34,000,000; in Ireland they do not amount to 15,000,000.

AGRICULTURAL MUSEUMS.

Two have recently been established in Ireland.

CORN LAWS.

When the average price of wheat in the British market is under 70s. ($15.54,) per quarter of eight bushels, the importation of foreign grain is prohibited; when the average price is over 70s. the importation is permitted, on the payment of a duty of 17s. a quarter.—This was under the old corn law. The maximum price has since been reduced to 60s. per quarter.

COLLECTIONS.

Early Rising.—There is no time spent so stupidly as that which inconsiderate people pass in a morning between sleeping and waking. He who is up may be at work, or amusing himself; he who is asleep, is receiving the refreshment necessary to fit him for action; but the hours spent in dozing and slumbering are wasted without either pleasure or profit. The sooner you leave your bed, the seldomer you will be confined to it. When old people have been examined, in order to ascertain the cause of their longevity, they have uniformly agreed in one thing only, that they "all went to bed and rose early."—*Gardeners' Gaz.*

The German Press.—It is calculated that ten millions of volumes are annually printed in Germany, and that there are upwards of fifty thousand authors of one or more books.

Encomium of Socrates upon Agriculture.—"Agriculture," says Socrates, "is an employment the most worthy the application of man, the most ancient and the most suitable to his nature; it is the common nurse of all persons, in every age and condition of life; it is the source of health, strength, plenty and riches, and of a thousand sober delights and honest pleasures. It is the mistress and school of sobriety, temperance, justice, religion, and in short of all virtues, civil and military."—Socrates would no longer be counted a sage in this enlightened age; for even many farmers have discovered, that his counsels are erroneous, and that agriculture is subordinate to the more *genteel* pursuits of life; and they therefore wisely resolve to make their sons measurers of tape and molasses, or retailers of law, rather than tillers of the soil.

Measuring light.—Sir John Herschell has lately invented an instrument for measuring the intensity of light, and he has found, that at the Cape of Good Hope this is twice as great as in England. "Although temperature has a great deal to do with plants," remarks Prof. Hall, "probably light has much more."

ARTIFICIAL MEADOWS.

The vast benefits resulting from artificial meadows, or in other words, of selecting for them plants of our own choosing, and alternating with grain and root crops, is strongly illustrated in the following extract from Yvart, a French agricultural writer.

> "If meadows," says he, "be the nerve of good husbandry, it is, above all, to artificial meadows we must apply this great truth. The state of those cantons which have adopted the new system, is now as brilliant as it was before wretched and miserable. Alsace has put on a new face since the introduction of clover, and wheat crops have been increased more than one-third. The village of Sebach, under the old system, bought annually 180,000lbs. of forage, and now sells 150,000. The canton of Virien, which gave formerly only rye and buckwheat, (and poor crops of these,) now gives abundant crops of fine wheat. This is altogether owing to clover and gypsum. The same remark applies to the department of Doubs. In the departments of the Seine and Oise, the four year rotation is adopted, of which clover is the basis, and moro than double the produce is raised for exportation. In Varenne, the soil of which is a poor sand, the same effect is produced, by sainfoin, instead of clover. In a canton of the department of Loiret, M. Segret has doubled his income by the introduction and culture of Lucerne."

THE BUDGET.

Cutting Bushes.—Oliver Moore asks, at what season bushes, sprouts and timber should be cut, that they may not grow again—and if the moon has any influence in the matter? If we are to regard popular opinion, the old moon in August is the propitious time to cut bushes, &c. to prevent their sprouting again; and so far as we have had experience, it goes to confirm popular opinion. In August, there is probably less sap circulating in trees than at any other time in summer, and consequently there is less disposition to throw up new sprouts; while the intense heat of the season, operating upon the wounds, tends to destroy vitality. All we will pretend to say in regard to lunar influence is, that there is ordinarily a more abundant flow of sap in the new than in the old moon. We therefore advise that bushes be cut in the old moon in August. Mr. Moore is informed, that the entire volumes of the Cultivator may be had, either stitched or bound.

Short-Horn Bull.—George P. Hawley, of Frankfort, Herkimer, asks us where he can buy a full blooded Short-Horn bull, spring calves, &c. and John Sommer, 3d, of Passumpsic, Vt. informs us he has such a bull to sell. C. N. Bement has also one or two. We have opened an advertising page particularly for the buyers and sellers of farm-stock, implements, seeds, &c.

Foreign Agricultural Periodicals.—A correspondent, J. M'M. asks us to recommend to him a foreign agricultural journal. We recommend the Quarterly Journal of Agriculture, published quarterly at Edinburgh, and the Farmers' Magazine, published monthly in London, both or either, as the best we are acquainted with.—Our correspondent will requite all obligations to us, by sending the result of his pending "experiments," favorable and unfavorable, in the Miami valley.

Silk Culture in the District of Columbia.—Our Washington correspondent writes—"Besides a number of individuals who have commenced growing multicaulis in this district, the Washington City Silk Company have purchased a farm near the city, at $12,000, have planted 200,000 buds, and are feeding the worms from five ounces of eggs. The company have also purchased three of Gay's Machines, and intend to manufacture all the cocoons they can either make or purchase in the district." And we hope they will employ in their labors, the invalid, the indigent and the young. Thus they may feed the hungry and clothe the naked, without serious prejudice to their interests.

Thrashing Machines.—It is out of our power to add to the information we have published on this subject. In answer to the inquiry of J. D. Rodney.

THE "ROBINSON FUND."

"For the encouragement of those who feel disposed to contend for these premiums, I have to inform you, that the seat of justice of Lake county has lately been located in the town where those premium lots are situated, and which will greatly enhance their value. May they be as nobly won, as they will be freely given. I remain, respectfully, SOLON ROBINSON."

CORRESPONDENCE.

Legislative Encouragement to Agriculture.

The following is an extract of a private letter to the conductor. The writer is a farmer. His letter will show that he is a gentleman of talents, and a patroit. We do not feel at liberty to give his name. It matters little whose hand records truths, if they concern, as the subject of this letter does, the most important interests of the state. We commend the subject matter to the serious attention of our readers, of all classes.

June 1, 1839.

J. BUEL, Esq.—Dear Sir—I intended to have written to you immediately on the rising of the legislature, but ill health and other engagements have compelled me to put off till the present time. Is it not vexatious, that after every thing had been put in such a train as to ensure success, our agricultural and silk bills must have had the go by, under the paltry excuse that they could not be suffered to pass without a full discussion. From Mr. ———, I should have expected nothing better; he has been opposed to aiding agriculture from the beginning; but that Mr. ——— should have done the same is to me surprising. Talk of importing silk to obtain the state premium, under a law for the protection of *domestic silk culture,* and as carefully guarded as was ours, how absurd? It was enough to make the blood of an honest man boil, to read the debates in the assembly on the agricultural bill. To hear the men whom the farmers sent there for far different purposes, than to abuse them, putting the horse jocky, the blackleg, and the avowed swindler on a par with the owner and cultivator of the soil, is intolerable. How came these men in the assembly? how came they by the education which was supposed to have fitted them for that place, and which in its legitimate effects should have made them gentlemen? They received, the most of them, their education at places for which the farmers of this state have paid above two millions of dollars; farmers by their votes placed them there, and gave them their power; and when farmers asked that they should have the use of some $25,000 annually, these men had the effrontery to talk of legislative aid to agriculture, being "arrant quackery?" Was it quackery when legislative grants endowed colleges and academies; and fenced the professions with legal enactments, which in effect has made them a privileged class? which has given them a power they are now using, to kick down the men who claim the right to rise to the same level with themselves? Do not understand me as casting these censures upon the whole legislature. We had some noble hearted supporters there among the professions; men whom our opponents dared not meet with an argument, but rather chose that dishonorable weapon, a sneer. But it is a melancholy truth, one apparent to all, that every thing in state legislatures and in congress, is opposed or supported, more with reference to political effect than any thing else: every thing is made subservient to the support or the overthrow of a party. It is one of the darkest of the signs of the times, that the merit or demerit of a cause has little to do with the success or failure of a measure, and that the mass of the people "love to have it so". After all the farmers have no one to blame but themselves. It is for them to say, whether they approve or disapprove the conduct of their servants, or rather as the times go, their masters. It is for them to say whether the sneers of a ——, or the atrocious language of a ———, shall be submitted to with patient approval; whether when they ask for bread, they shall not only be turned away with a stone, but cudgelled off with blows and flagellation.

There is in my opinion no disguising the fact, that we are fast becoming a people of caste; and that *rank* in reality, if not in name, is as much felt here as in England. On one side are the producers, on the other the non-producers; on one side the mass of the people, the "laymen" as they were contemptuously called in the late legislature, on the other the professions, as they are in courtesy called. The mechanic and the farmer wish to improve, to rise; and the beneficed, and privileged, are determined they shall not. Their rights are secured by law, and they make, they frame, and they expound the laws. They say what interest shall be aided and protected, what depressed or punished for its presumption. They grant millions for colleges to educate their sons, and keep their ranks full; we ask for hundreds or thousands to instruct and benefit the mass, to endow a school of agriculture, or societies for promoting it, and are told by these men we are fools, do not know our own business, and that aid to us would be the vilest quackery and folly. Well, unless I am mistaken, "we bide our time;" we will have our place in the temple we have erected, or we will pull it down.

I know not what you think of these matters, for I have not seen the present volume of the Cultivator, but I think I know your opinion so well as to have no doubt of your sentiments. At any rate I have written freely, for I feel deeply, and on this subject it is the duty of farmers to speak fearlessly. We must not be discouraged, but gird up ourselves for another effort. The subject must not sleep; we can, and we will be heard. We will not forever pay, and receive nothing; forever be filling the treasury to see it squandered on objects and for purposes, which to the improvement of agriculture in consequence, are but as the dust of the balance.

Cure for the Stifle.

Lincolnton, N. C. May 28, 1839.

J. Buel—Dear Sir—I noticed in your February number of the Cultivator, page 207, a cure for stifle, by external applications; to wit, a decoction of sumach and white oak bark, &c. This is new to me and may be very effectual, but there is a remedy which I have practised, which is certain, simple and quick, which I will communicate, and if you think it worth notice, may recommend it.

"Fasten a strong rope or chain round the foot-lock of the injured leg, and let a strong man hold it; then have the horse moved forward, while the rope is held fast by the person behind, pulling the rope so as to occasion the leg to be extended back as far as it can be drawn. Let this be done three or four times before the rope is taken off."

I have never known it to fail to make a cure on the first application, but the gentleman who gave me the information, and applied it to a horse of mine, told me that when the stifle had remained for some time, the first jerking might not effect a cure, and in that case it would be necessary to repeat it in a few days. I do not know the cause of the lameness, but was told by the same gentlemen, who informed me of the remedy, that it was occasioned by the slip of a bone, about as big and long as a man's fore finger, at the thigh joint, near the flank, and that the jerking the leg back restored the small bone to its place. If that be the cause, perhaps the decoction mentioned in your February number might assist in the cure; but I never failed to relieve a horse of lameness of stifle, by putting the leg back, as above described, and have cured several.

It might be of importance to some to know how to judge when the lameness of a horse is what is called stifle. That can be ascertained by leading the horse over a log, fence or bars, eighteen inches or two feet high. When the horse is stifled he will drag the lame leg over the log, and the pain in the thigh joint, preventing the animal from raising the leg up, as it does in stepping over a fence or log, and when first afflicted, seems to be very painful, and makes the animal sweat very much. Respectfully yours, &c.

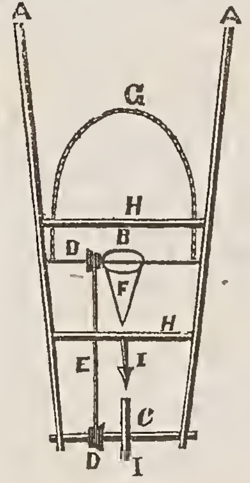
ROBERT H. BURTON.

P. S. In pulling or jerking the leg back, care should be used that it should be directly behind, for if turned to the one side or the other, it may be injured. My horse, which was relieved in this way, had travelled a hundred miles quite lame, and sometimes in great pain, and when turned out after one operation, showed no more lameness, and set to playing.

Mr. Whalen's Cultivator.

Whalen's Store, May 17, 1839.

[Fig. No. 20.]



J. Buel, Esq.—Dear Sir—In compliance with the request of Mr. Bailey, I herewith send you a description of my drill-barrow, with a drawing of the same. It excels, for cheapness and simplicity, anything I have seen.

A A are side pins or arms, 5 feet long, 1½ inches thick, made of white ash or oak. B, tin barrel or cylinder 8 inches long, 5 inches diameter in the middle. 3 inches the ends. C, wheel 13 inches diameter, made of 1½ inch oak plank, banded with hoop iron. D D, pulleys or wheels, turned tapering, 5 inches diameter at large end, 5 grooves in each. E, band made of cotton, ⅜ inch diameter. F, hopper suspended below tin box to catch and carry seed to ground, tapering to 1½ inches in the clear. G, trace chain dragging behind to cover seed. H H, cross ties. I, coulter suspended from cross tie, so guaged as to make a small furrow for seed.

The tin barrel is perforated in the middle with 4 holes, equidistant from each other, large enough to pass a No. 3 shot, or 2 or 3 seeds at a time; about an inch from the end is a hole 1 inch in diameter, for receiving the seed, stopped with a cork. The axle of the tin barrel is of wood, passes through the same, and is about 1 inch diameter. I generally use 2 trace chains instead of 1. With the tapering whirrs, the barrel can be geared to drop faster or slower. I have found it preferable to sow an extra quantity of seed, and thin down in order to get a good stand. A communication appeared a short time since in the Cultivator, recommending to transplant or dibble out the plants. I never could succeed well with the plan, and all that Cobbet and others may have said in its favor will not persuade me to adopt it.

In conclusion, I would say, I grew last season 1,600 bushels ruta baga, large measure, on 2 acres ground.

Respectfully yours,
SETH WHALEN.

Physiology—Vegetable and Animal.

J. Buel—Dear Sir—By the way of extracts, I now further proceed to observe, that while all writers agree, that the origin of the vegetable kingdom is by generation, its growth by nutrition, and a termination by death, but in an organized structure and an internal living principle; *physiologists* differ in the powers with which the living principle is endowed, and the effects it is capable of exerting. In the plant it is limited, so far as we are capable of tracing it, to the properties of irritability, contractibility, and simple instincts; in the animal, it superadds to these properties those of muscularity, sensation, and voluntary motion.

There have been, indeed, there still are, physiologists who, not adverting to the extraordinary effects, which the power of irritability is capable of producing, when roused by different stimulants, and under the influence of an internal and all-pervading principle of life, operating by instinctive laws and instinctive actions, or those, as we shall show hereafter, which are specially directed to the growth, preservation, or production of a living frame, or any particular part of it,—have conceived plants as well as animals to be possessed of sensation and muscular fibres; and as sensation is the result of a particular organ, and the organ producing it is connected with various others, have, at the same time, liberally endowed them with a brain, a heart, and a stomach; and have very obligingly permitted them to possess ideas, and the means of communicating ideas; to fall in love and to marry, and thus far to exercise the distinctive faculty of volition. The whole of which however, is mere fancy, grounded altogether upon an erroneous and contracted view of the effects of the principle of irritability, when powerfully excited by the influence of light, heat, air, moisture, and other causes.

In reality, such kinds of loves and intermarriages are not peculiar to plants, but are common to all nature; they exist between atom and atom, and the philosopher calls them attractions; they exist between congeries and congeries, and the chemist calls them affinities; they exist between the iron and the loadstone, and every one denominates them magnetism. Nor let it be said, that in these cases of mutual union, we have nothing more than a mere aggregation of body; for we have often a third substance produced, and actually generated, as the result of such union, far more discrepant from the parent substances, both in quality and feature, than are ever to be met with in vegetable or animal life. Thus, if an acid be married to an alkali, the progeny brought forth will be neutral salt, possessing not the remotest resemblance to the virtues of either of its parents. In like manner, if alcohol be married to any of the more powerful acids, and the bans be solemnized over an altar of fire, the offspring engendered will be a substance called ether, equally unlike both its parents in its disposition.

But in this it may be said that we have no instance of a multiplication of species; only the production of a third substance; yet in many cases we have instances of multiplication also. Such especially are those wonderful increases that occur in the case of ferments and contagions.

A few particles of yeast lying dormant in a dessert-spoon, are introduced into a barrel of beer, or of any other fermentable fluid, and in a few hours propagate their kind through the largest vessel that was ever manufactured; so that at length every particle of the fluid is converted into a substance of their own nature.

The terms loves and marriages will just as well apply to these as to the vegetable creation. The cause of the respective unions, and of the changes that take place in consequence of such unions, are nothing more than elective attractions; in the mineral and gaseous kingdoms produced by what chemists have denominated the principle of *affinity,* and in the vegetable, by what physiologists have called the principle of *irritability.*

No experiment or observation has hitherto proved vegetables to be possessed of any higher powers than those of irritability, contractibility, and those instinctive energies which we shall hereafter show, are dependent upon the principle of life.

Plants, then, like animals, as has been already observed, are produced by generation, and through the medium of ova or eggs. The exceptions to this common rule are few, and they occur equally in both kingdoms. The egg of the plant is its seed; which is sometimes naked, but more generally covered with a pericarp, or called in popular language, pod. Stripping off this outer covering, we find the seed to consist internally of a *corculum,* or heartlet, and externally of a fleshy substance, surrounded with a double integument, sometimes single, and sometimes bifid; these are called seed-lobes or seed leaves. In the common kidney-bean, we have as striking an instance as in any plant, just peeping in two distinct segments above the ground, as soon as the seed has began to germinate. The cotyledon is that part necessary for the germination and future growth of the seed, and may be denominated its lungs. Plants possess lymphatics and air vessels: through the former of these it absorbs the moisture of the soil into which it is plunged, decomposes a part of it into its elementary principles, and conducts these principles, together with the undecomposed water, to the corcle or heartlet, which becomes stimulated to the process of germination by the oxygen thus set at liberty. It is the corcle which is the true *punctum saliens* of vegetable life, and to this the cotyledon is subservient. The corcle consists of two parts, an ascending and a descending; the former called its plumule, which gives birth to the trunk and branches; the latter named its rostel, which gives birth to the root and radicles. The position of the corcle in the seed is always in the vicinity of the *hilum* or eye. The first radicle or germinating branch of the rostel uniformly elongates, and pushes into the earth, before the plumule evinces any change. The radicles consist chiefly of lymphatics and air-vessels, which serve to separate the water from the soil, in order that the oxygen may be separated from the water.

Hence originates the root, unquestionably the most important part of the plant, and which in some sense may be regarded as the plant itself; for if every other part of the plant be destroyed, and the root remain uninjured, this organ will regerminate, and the whole plant be renewed; but if the root perish, the plant becomes lost irrecoverably.

The solid parts of the trunk of the plant consist of *cortex,* cuticle, or outer bark; *liber, cutis,* or inner bark; *alburnum,* or soft wood; *lignum,* or hard wood; *medula* or pith. The trunk enlarges, by the formation of a new liber or inner bark every year; the whole of the liber of one year, excepting its outermost layer, which is transformed into cortex, becoming the alburnum of the next, and the alburnum becoming the lignum.

All the concentric circles which are produced in the trunk of a tree by the growth of every year, are still visible after the conversion of every other part into lignum or hardwood, and we can trace its age with a considerable degree of certainty, by allowing a year for every outer circle, and about two or three years for the complete lignification of the innermost.

The respective vessels of the vegetable system are adducent and reducent, or arteries and veins; the arteries or sap vessels may be seen by the naked eye; the veins or returning vessels bring back the elaborated sap from the leaves to the liber for the new layer of the existing year.

The lymphatics lie immediately under and in the cuticle; immediately below these lie the adducent vessels or arteries; they are the largest of the vegetable vessels, rise from the root and communicate nutriment in a perpendicular direction. Interior to these lie the reducent vessels or veins; which are softer, more numerous, and more minute than the arteries.

This double set of vessels is possessed of an opposite power, and acts in an opposite direction, the one to convey the sap or vegetable blood forwards, and the other to bring it backwards; being thus sufficiently able to establish a circulatory system.

It should be observed, that the matter of fibrine, or the principle of the muscular fibre which exists in animals, also exists in vegetables. Dr. Hales cut off the stems of vines in the spring, and by fixing tubes on the stumps, found that the sap rose in many instances to the height of thirty-five feet. Tubes have been fixed to the large arteries of animals, as near as possible to the heart, in which the blood did not rise higher than nine feet.

Plants are also possessed of cutaneous secornants or perspiratory vessels; and in many plants the quantity of fluid thus discharged is very considerable. Dr. Hales in a very accurate set of experiments determined that the sunflower threw off or perspired nearly half its own weight in twenty-four hours.

Plants, nevertheless, do not appear to have the smallest basis for sensation, admitting that sensation is the result of a nervous system. The vessels of plants do not appear to possess any muscular fibres, yet we have evident proofs of the existence of a contractile and irritable power from some other principle; and a variety of facts occurring in making it highly probahle that it is by the exercise of such a principle that the different fluids are propelled through their respective vessels; we have abundant proofs also that a contractile power may exist independently of muscular fibres in the animal system.

In what part of a plant the vital principle chiefly exists, or to what quarter it retires during the winter, is not known, and we are equally as ignorant in respect to animal life. The plant yearly thrives and increases in bulk, puts forth a new progeny of buds, and becomes clothed with a beautiful foliage of lungs for the respiration of the rising brood; and with a harmonious circle of action, that can never be too much admired, furnishes a perpetual supply of nutriment, in every diversified form, for the growth and perfection of animal life, while it receives in rich abundance, from the waste of diminuation, and even decomposition of the same, the means of new births, new buds, and new harvests.

Thus every thing lives, flourishes and decays; every thing dies, but nothing is lost: for the great principle of life only changes its form, and the destruction of one generation is the vivification of the next. Yours, &c.

S. W. JEWETT.

Great return of capital laid out in agriculture.

Metuchen, N. J. June, 1839.

J. Buel, Esq.—Dear Sir—In conversation with a gentlemen, recently returned from England, who has had opportunities of visiting some of the best farms in the most improved agricultural districts of that country, and whose judgment in all matters pertaining to the soil is well matured both by study and practice, I was surprised to hear of the enormous difference in the results of agriculture between that country and our own. As an instance of the profits generally derived there, by men who commence farming, without any acquaintance with the practical department, but with only that knowledge which may be acquired by study, and judgment based upon observation of the methods and practice pursued by others, he stated, that he had visited a relative, who six years since, leased a farm of six hundred acres, at a yearly rent of seven hundred pounds, equal to about three thousand five hundred dollars. Now this to us would appear a good price to pay for the purchase of the same amount of land. Yet it was no more rent, than ordinary good land would readily command there, at that time. But by many who were not so well acquainted with the much ridiculed theory of agriculture, who had not applied themselves to the study of those sciences which are requisite to a correct and judicious management of any soil, and who were in fact ignorant of the very nature, and qualities of the soil, they were themselves laboring to obtain a competence from; by many such, the undertaking was thought, owing to the previous occupant's ill success, as next to folly itself. Not so with the present lessee. Although he had never "held the plough, or driven," and perhaps to this day, has not yet "fretted the skin from off his maiden palms," yet from acquired knowledge of the properties, and capabilities of every soil, when treated according to the manner indicated by its qualities, and by a liberal system of *feeding* as well as *cropping* that soil, he has been enabled not only to pay the apparently enormous rent above mentioned, but also, to reap a rich reward for his enterprise.

For the first two or three years, he sunk annually about fifteen hundred pounds; but this was expected, as from the situation in which he found the land, the most lavish expenditure was required, to bring it up to that state of productiveness which he knew it to be capable of. Yet this was willingly afforded; not with that blind recklessness with which many of our gentlemen farmers commence operations, but with strict attention to the aptness of his measures, and with the view constantly before him of their future and lasting benefit to the soil. And while liberality was the ruling sentiment in all his operations, yet a just economy both of ways and means, was never lost sight of. I have given you as yet, only an idea of part of the expenditures; I will mention a few more, that when the profits are named, they may not seem disproportioned, or that the whole system may not appear too chimerical to encourage gentlemen of capital to pursue it in our own country. Among other items he mentioned, that it cost him every year about two hundred and fifty pounds, one thousand two hundred and fifty dollars, for oil cake, and that he yearly made use of two thousand bushels of bone dust, the cost of which was of no consequence, as he would have it at any price. That into his barn yard there was carted every morning, a large two horse cart load of straw, and that he used a root slicer that with two men, would cut three bushels of turnips per minute.

These few particulars may enable the *initiated* to account for the success attendant upon his undertakings, and to understand how, in favorable seasons, he manages to make one thousand pounds, or five thousand dollars *nett* profit from a farm of about six hundred acres.

Culture of Corn.

Setauket, Suffolk co. May 18, 1839.

Judge Buel—Sir—For some time I have thought of offering my mode of treating the corn, which I consider the most important among the grain crops; and the springing of the young plants prompts me again to submit it. Whether manure has been spread before ploughing or only placed in the hills afterwards, I adopt the same practice. As soon as the corn has got up, so that the rows or lines can be distinctly seen, I run the *plough* through as near to the hills as may be without displacing the plants, to the depth of five inches, throwing the earth from the hills; if moles or mice are plenty in the field, both ways, if not, only one way. The rows are then gone over with the hand hoe, the hard surface or crust immediately about the plants stirred and broken, and the contiguous weeds or grass destroyed: this is the first dressing. After about ten days, set in the plough in the same manner as before, if it has been ploughed through only one way; if both, reverse the furrows and let the hoe be used to loosen the earth about the plants, and to draw a little fresh soil to the hill, at the same time eradicating all weeds and grass near the plants. Now we have ended the second lesson, and will be ready at the proper time for the third and fourth, or more, as the soil or season may require, with the cultivator or harrow to break down small hillocks or ridges, and to keep a soft surface between the rows, that will absorb the showers or dews, when a hard surface would be but little benefitted, taking care at each time, to draw a little new mould to the hill, yet leaving it at the last dressing with a wide square hill, but slightly elevated. This little rise about the corn hill will help to support it at the autumnal gale, and will not turn the showers off to the injury of the crop. This management may seem not exactly orthodox; but I fancy I derive some advantages not to be obtained by the use of the harrow or even cultivator alone. Those mischievous miners, the moles and mice, are more effectually opposed in their operations, a deeper and softer bed is prepared for the roots to strike into, and greater extent of surface is exposed to be heated by the sun's rays; which is in effect protracting the summer a week or ten days, time enough not unfrequently to save a crop. A common saying with our farmers is, corn only wants hot weather; and the fact is notorious, that a fair crop of corn may be obtained by nice management, in a season so dry that any other grain crop would fail almost in toto. The harrow and cultivator scarify the ground, but do not lay it open with a bold incision, nor leave the corn hill on a prominent ridge or hillock at the commencement of growth, when nothing but heat seems necessary to the vitality and health of the plants. If it be objected, that by this use of the plough we assist the escape of vegetable food, in the form of carbonic acid gas and volatile alkali, I reply it may be so, to the amount of six or eight per cent, an inconsiderable matter compared with the accelerated maturity of the crop. Should you deem these remarks of consequence enough for insertion in the Cultivator, they are at your service. Respectfully yours,

ARCH. JAYNE.

The Silk Business.

Goshen, May 12th, 1839.

J. Buel, Esq.—Dear Sir—The silk business seems to be on the advance in this country. Rapid indeed has been its progress within the past six years, if we consider the quantities of trees raised, as a part of the business.

As almost every one has an opinion of their own, this opinion, if founded on personal observation & experience, might be worth committing to paper, especially as there is so much yet to be learned upon the subject; I have taken the liberty to trouble you with a few of my thoughts upon the subject, presuming that you will not suffer anything to have a place in the columns of your paper, which would not tend to promote the end for which it was designed. The business of making silk in this country, will undoubtedly, at no very distant period, be a great one. Many of our best farmers, who are now deterred from engaging in the business through ignorance or fear of the expenses incident upon a new business, will, when they see from the experiments of their more enterprising neighbors, the ease with which the operations are performed, that it is as simple as almost any branch of husbandry, and more than all, that if properly managed, it yields a rich return from a small investment, be much more ready to engage in it. Yet at the commencement of the business, some judgment and foresight is necessary, more especially in the selection of the right kind of trees.

The white mulberry is a good hardy variety and produces silk of good quality, but the quantity of foliage it produces to the acre is much less than that of some other kinds.

Immense quantities of the morus multicaulis have been grown in this country, but I suspect more for the purpose of speculation, than from any desire to promote the manufacture of silk. I had occasion not long since to take a journey into Massachusetts, on business, and while in Amherst, I became acquainted with Mr. Timothy Smith, and several other intelligent gentlemen, engaged in the silk business. Mr. Smith, I considered, as the most candid man I conversed with, and who has been in the business the longest. He commenced in 1832, with the white mulberry, found that the leaves made good silk, but the quantity of foliage produced to the acre was small. He then successively tried the multicaulis, Canton, and Alpine, which he pronounced only a variety of the Canton. He gave a decided preference to the two last varieties, alleging as his reasons, that the quantity of foliage to the acre from Canton trees, was nearly as large as that of the multicaulis, while the leaf of the former seemed to be more palatable to the worms, and did not create disease amongst them, as the leaves of the multicaulis did, owing to the quantity of moisture in the latter. The Canton proves to be a much hardier variety than the multicaulis, as he has proved by actual experiment, that they will stand our winters while the multicaulis will not. Other experiments and observations which I have not time nor room now to detail, convince me that the Canton tree is the best adapted to our northern climate, and when the rage for buying up multicaulis cuttings, at 4 cts. a bud has in a measure subsided, and the business of making silk begins to claim a share of public attention, this tree will be more sought after.

I have a piece of ground very mellow, but not very rich, which I intend to sow with ruta baga. Would it be a good plan to sow to buckwheat and turn it under as food for the turnips? Yours with respect.

CHAS. STRONG.

Bloody Murrain.

Black Locust Grove, Mo. May 3, 1839.

Hon. J. Buel—Sir—I will now give you (and if you think them worthy of it, through you to the public) *my own* observations and experience about the "*bloody murrain*," a disease I never heard of among cattle till I moved to this country. I have tried the "tar," sir, to my own satisfaction.* It may have cured some cattle, but not one of mine, for I have lost six head of valuable cattle in the last five months with it, and I tried tar on all that I could get to in time to do any thing with, but one, and it has failed, entirely failed, to do any good. Indeed, sir, I have come to the conclusion, that there is no specific for it; but like cholera, some few cases may be cured, but ninety-nine out of one hundred will die. It is a most painful, dreadful disease; those that discharge the blood through the urine and bowels, suffer much less pain (though no less fatal) than those that bleed internally; and I believe the best preventive is regular feeding, and not too sudden a change of food. Now for my reasons for thus believing.

In the first place, the spring and fall are the times in the year it prevails most; the poorest or fattest are the most liable, though some exceptions, both as to time and the order they are in. Last fall I had a very fine heifer (one that had taken the premium at our fair,) in fine order which was the first of mine that took it; she ran in a lot through which I was hauling corn to the cribs, and while we were unloading she would usually gather up the falling ears, and I would throw her the nubbins. On the next first day of the week, she did not get any corn, as the grass in the lot was thought sufficient. On Monday following she died. In the last of February I had two steers that died. It being wet, the cattle did not eat their food clean, consequently they did not receive their usual quantity of aliment; and being weaker than the most of my other cattle, they were kept off, and consequently became excessively hungry. I then had another heifer that I prized very highly. In order to save her, as she was getting poor, I had her fed an extra meal, and the very next day she died. Here I had ample opportunity to try the tar, for from day light till night (and the night before she was well, at which time I began to give her the extra feed,) I had her to operate on, but to no purpose. Well, sir, when grass came and would afford a good bite, one of my neighbors had a bull which he had kept upon dry food. I wished to get some of his calves, and obtained the use of him; turned him on my pasture, quit giving him dry food, and in three days he died. So, then, I conclude that too sudden a change from dry to green, or from green to dry, will produce it; hence its prevalence in the fall and spring. Or permit a fat animal to get very hungry, or a poor one to get very hungry, or unusually full, will produce it; and when produced it most generally brings forth death.

---

* Mr. Smeally wrote us, after the insertion of his communication, recommending tar, that it had failed with him in some subsequent experiments, which we forgot to notice.—*Cond.*

While I am writing, I will mention a practice I fear is coming into vogue, which in my opinion is not only dishonorable, but calculated to do harm. It is the custom of puffing certain seeds into notice, and then to cheat the community with them. For instance Baden corn was posted through our newspapers as the brag corn, whether as to number of ears to the stock or yield to the acre. Well, sir, we had some forty bushels brought to our country, and I do most positively affirm, taking the bushel I got as a specimen, there was at least one-fifth wholly unfit to plant, yet it cost us five dollars per bushel. There was not only every variety, from the hard flint up to the common *white and yellow*, but the nub or blossom end corn, and some of it actually rotten. Again, sir, a man who has Rohans for sale at St. Louis, at eighteen and three-fourth cents for each potato, (as I am credibly informed,) says each potatoe *will plant three hills, and each hill will yield one bushel of potatoes.* What must be the size of a potatoe hill to get a bushel of potatoes from it? Yours as ever,

A. H. F. PAYNE.

N. B. Now, sir, do as you think best with this communication, but if you publish it, let it appear in the best garb you can, for I never was in the habit of writing for the public. A. H. F. P.

New Disease in Sheep, &c.

JUDGE BUEL—Sir—Mr. Bailey solicits information of your correspondents and patrons, respecting a new disease which has recently attacked his sheep, described in the May No. of the Cultivator. By the symptoms therein described, I should attribute the cause, to his sheep partaking too freely of the stock or root of some poisonous plant. A powerful application of quicksilver to the skin sometimes will produce similar symptoms.

Treatment, blead them immediately after the attack, by opening the vein which lies between the innermost corner of the eye and nose; or bleed them in the nose. By the sheep's taking the blood it answers as a mild purge.

Treatment for blindness.—By the assistance of a quill, blow a few grains of pulverized blue vitriol into the eyes; or for a milder remedy add an equal quantity of fine loaf sugar with the vitriol. I have used the above with good success in removing the film from horses and cattle also.

Breachy sheep.—Good fences are the *best remedy* for this complaint; but when fencing timber is scarce, I have known the following application to be safe and effectual. Part the skin perpendicularly, about three-fourths of an inch, so as to expose and cut the two cords on each hind foot, (which are about the size of the stale to a pipe,) between the dew claw and hoof; a few days should intervene between the two operations, that one ankle may heal before the other is operated upon. Yours, &c.

May 12, 1839. S. W. JEWETT.

On the principle of fear or timidity in Horses.

MR. EDITOR—Sir—I send you the following remarks, trusting that you may find them worthy of an insertion in your periodical; for I presume that any thing that tends to elucidate the nature of that noble animal the horse, comes properly within the province of your remarks; although the appellation of your pamphlet is the Cultivator.

It has been asserted by some authors, whose names I do not recollect, "that the superior knowledge that mankind possesses, is partly owing to the power of handling or feeling that they have, and that were it not for this faculty, their knowledge of objects would be very vague and indistinct." This I have no doubt is correct, for it is very probable that a child has but a very imperfect notion of objects until he begins to feel and handle them. A boy about a year old is frequently frightened at objects, such as a bright scarlet cloak, a large dog, &c. and this kind of fear continues, until he acquires some knowledge of their nature by feeling and handling of them; this faculty being the great corrector of our sight. It is very probable that a horse is in the same situation; nature never having bestowed upon him the faculty of handling or feeling, his knowledge of objects must be very vague and indistinct. As a proof that this is the case, it may be observed, that horses are not any more frightened at unusual sounds than mankind are, and they are on about an equal footing with man in regard to the sense of hearing. An uncommon sound frightens a man as much as it does a horse; the former's reasoning powers will no doubt some times refer him to the sound, but at an unusual noise with which both are unacquainted, the one will be as much frightened as the other. It may be observed further in proof of my position, that all animals that possess the power of handling are more intelligent than those that have not this faculty. The elephant, the monkey, and the dog, are much more intelligent animals, than the horse, the cow or the sheep. A dog by jumping upon objects and pawing on them, acquires a knowledge of their nature and dimensions. A monkey can handle any thing about as well as as a man, and an elephant has such a nice sense of feeling in his trunk, that he can pick up a pin from the ground, and this is one reason of his great sagacity. A dog can travel along a great way without seeming to be afraid of any inanimate object, while a horse is continually scared and frightened at such trifling things as the stump of a tree, a heap of stones, &c. But all this may be best exemplified by different animals in passing over a bridge; and as I have lived for a number of years within a few rods of one, I have had frequent opportunities of witnessing their actions. A horse who is not used in passing a bridge, most generally turns round on approaching it, and refuses to pass; he seems afraid, and acts in a manner that would seem to indicate that he knows nothing about the object of his fear, only that it has that impression on his senses, something like a child with a bug-bear. A cow and a sheep act very much in the same manner. But how differant the actions of a dog, a monkey, or an elephant. A dog passes over without any reluctance; a monkey would probably do the same. I once had an opportunity of witnessing the passage of an elephant. He approached the bridge carefully, and put on his foot, as if to test its strength, and having done so, he retired to one side; his fear, in this instance, did not seem to arise from any other consideration but that the bridge would not be strong enough to support him; and after his keeper examined the bridge thoroughly, he passed over without much reluctance.

It may be stated as an objection to this method of reasoning, that the domestic cat is an animal possessing the faculty of handling, and is not remarkable for any great intelligence. I differ very much from this opinion; for I consider puss as a clever animal, and she can cuff ears as dextrously as any of our most expert matrons. I have been quite astonished at what I have seen some cats perform, having owned one that could open every door in the house, almost as well as any biped in it. From these remarks, I think it will appear, that the faculty of handling is a great cause of superior intelligence amongst animals, and the lack of it in the horse is one reason of his great timidity or liability to being frightened. But in order to make this appear as plain as possible, I will state one example further. I once caught a species of porcupine, and on bringing it home I introduced it to the notice of a cat. Puss was evidently disconcerted, but on its moving towards her, she gave it a smart scratch or two, and then retired. I next laid it before a dog. He appeared at first embarrassed, but mustering courage, he began to paw it, and at last he bit it; but on finding it pricked him, he kept walking around it in search of a vulnerable part. The last animal I introduced it to, was the horse. He leaned down his head for the purpose of smelling at it. Now this way of smelling, although it may serve a useful purpose for distinguishing the animal food, is rather an awkward way of ascertaining the nature or quality of an object; and as soon as he saw the procupine move, he started suddenly back, and had he been at liberty, would no doubt have bounded off at full speed. In this instance the horse would never know any thing of the nature of the porcupine, and would be as readily frightened at it at any future time as ever; but the result would be different with the dog or cat, who would probably always recognize it afterwards. But after all, could a remedy be devised for this excessive timidity in horses, and their liability to be frightened, it would, doubtless, be a great improvement. The use of blinds is an attempt at this; but it may be questioned whether they are of any advantage, although they may prevent the animal from seeing so many objects at his side; yet they rather increase than diminish his chance of being frightened, from any thing coming suddenly up from behind. Hoping that these hints thrown out, may be the means of suggesting to some of your ingenious readers, a method by which this dangerous disposition in horses may be ameliorated, I remain, yours truly.

Canal Repairs.

Schenectady, 16*th May*, 1839.

DEAR SIR—When the Erie canal was making over the flatlands at Schenectady, I remarked to the engineers, that in all cases where the water was to be sustained by artificial banks above the ground, I thought it would be liable to breaches, unless the banks were sheet piled.

All such observations were treated contemptuously, as presumptuous from observers who did not pretend to make water run up hill.

In consequence of trusting to such banks without sheet piling, they have been broken by the water, and required repeated repairs, till the amount stated in the report of the commissioners of the canal fund, to the legislature, of 3d January, 1839, under the head "repairs," is $4,284,366.24. And I presume one million more may be added for individual damages by detention in consequence of the breaches. These sums would make a ship canal of the Mohawk river from this to Utica. And before ten years more shall have elapsed, the cost of repairs will probably enlarge the sum sufficient to meet the expense of continuing the ship canal to lake Ontario. And yet we are to jog on, enlarging and repairing the artificial banks, because we began wrong and cannot acknowledge the error nor retract.

The breaches in the enlarged canal will be attended with double the cost of repairs, and more to individuals, because a large sheet of water, when suddenly let loose, will force its way with more than twice the power of a small one. But the banks of the river, being ascending, would not break, nor would the bottom fall out, as that of the canal has done, to the depth of fourteen feet below the ground, by means of quicksand, on the flats in Rotterdam. Respectfully,

D. TOMLINSON.

Soap-boilers' Waste.

Fishkill Landing, May 27, 1839.

J. BUEL—Dear Sir—I have recently learnt that soap and tallow chandlers throw away annually a large quantity of liquid, which they call salt lye. It is possessed of a lyey sort of substance, and is so strong that the smallest quantity when applied to vegetables while growing will entirely destroy them. If this sort of lye can be made worth anything to the farming interest, you will do a favor by saying in what manner, in the next number of the Cultivator. We have a very pernicious sort of a weed or plant among us, known to some by the name of snapdragon, to others by stink weed, (bears a yellow flower) which, should it continue to spread in our lots as it has done for some few years past, will render our farms almost useless. Information as to the course to be pursued to destroy it will be very highly prized by many of the farmers of Dutchess and Orange counties. Should you tell us how to prevent the ravages of the locust-borer upon the young locust, it will be looked upon as valuable. Yours truly.

A FARMER.

REMARK—The lees, or salt lye, of the soap boiler and tallow chandler, we believe, if thrown upon a compost heap, or sufficiently diluted with water, would serve as a fertilizing material in the soil. It must contain alkali, lime, and probably some oil, all of which will prove beneficial to the soil. Urine is destructive to vegetation, if applied to growing plants in a fresh state; and yet it is a powerful fertilizer when suitably diluted, or mixed with earthy materials, and modified by fermentation. The pernicious weed mentioned by our correspondent we believe to be *linaria vulgaris*, sometimes denominated *yellow toad-flax*. a perennial which spreads rapidly in clay grounds. The only means of extirpating it are those we have recommended for the extirpation of Canada thistles, star of Bethlehem, and other perennial incumberers of the ground—preventing the growth of their leaves by the good culture of hoed crops. We know of no preventive of the ravages of the locust-borer. There are either two varieties of this tree, one of which is not attacked by the insect, or the soils in which they grow make a difference. If our correspondent will cross the Hudson, and visit the farm of Messrs. Hallock, a little below the village of Milton, he will see hundreds, if not thonsands of the locust, of thrifty growth, which are not at all affected by the borer. These produce very few seeds.—*Cond.*

Questions and Answers.

Dover, Md. May 31.

JUDGE BUEL—Can your inform me who keeps hogs on an extensive scale, that I may get some information? Do you know of any kind of grass that could be cut by the middle of July or sooner, so as to yield a good return on a sandy loam?

Our corn crops are coming on very finely; plenty of rain, though at present rather cool. I was thinking as soon as my wheat is cut of sowing oats on the stubble immediately, and plough it under so as to afford a green crop, on which to spread lime in the fall for corn next year; is it a good plan?

P. S. RUTH.

ANSWERS

For pig farmers see our advertising sheet for Feb. Lucern will grow on a sandy loam, if rich and clean; and may be cut in Delaware by the middle of May, and will yield an abundant return. The oat crop after wheat may afford pasture, and may give some fertility to the soil, if ploughed under before it is destroyed by frost.

More "Last Words" About Millers' Tolls.

Rahway, May 15, 1839.

MR. J. BUEL—Dear Sir—It would not have been necessary for me to say anything more concerning millers' tolls, had not Mr. Walton's communications appeared in the last volume of the Cultivator; as they have not proved that grain contains the quantity of air they have asserted. But since they thought proper to have it inserted in this volume; and as you are receiving such a multitude of new subscribers to every new volume, they will see but one side of the question; therefore permit me to occupy a small space in your next number with a final and concise review of our former controversy. I will commence with Mr. David Walton's first communication on this subject; he has here asserted "that in solid bodies there is fixed air," of which fact perhaps nine-tenths of the agricultural community are ignorant. I will here observe, that it is hopeful that ten-tenths of the community may forever remain ignorant of this ignominious blunder of Mr. D. Walton's: Does he presume to assert that nothing is solid within itself? if so, he must be deficient of common sense, in so publicly exposing his ignorance; for this has forever been one of the foundation stones of all philosophers, that every substance or matter is solid within itself. I will here inform him that the minuteness of matter is far beyond all human conception. To illustrate this, I will introduce him to divisibility, and here inform him that there can be no substance of matter so small but that it can be divided, and it will have an upper and under side. I will quote the illustrations of D. Blair, under the head of divisibility. "1st. Since matter can never be annihilated by division, so we can never imagine it to be cut into such small particles that any of them shall not have an upper and under surface, which may be separated if we have instruments small enough for the purpose. 2d. It would be absurd to say that the greatest mass has more halves, quarters, or thousandth parts than the smallest particle of matter;" to prove that every particle of fluids are solid, I will not presume to go beyond the assumption of wise philosophers. I will quote Blair's observations under the head of hydrostatics. "Obs. 1. Heat or motion is supposed to be the cause of fluidity: for example, ice without heat is a solid—with heat, it becomes a fluid in water—and with more heat an electric fluid in steam. In the first state the atoms are fixed in crystals; in the second, are thrown into intestine motion; and in the third state, are forced asunder with an amazing expansive force." "2d. Philosophers have usually assumed that the particles of fluids are round and smooth, since they are so easily moved among one another." This supposition will account for some circumstance belonging to them. If the particles are round, there must be vacant spaces between them, in the same manner as there are vacuities between cannon balls that are piled together; between the balls smaller shot may be placed, and between them still smaller, or gravel or sand may be diffused; in a similar manner a certain quantity of particles of sugar can be taken up in water without increasing its bulk; and when the water has dissolved the sugar, salt may be dissolved in it and yet the bulk remain the same; and admitting that the particles of water are round, this is easily acconnted for. Mr. Walton further states "that he has found by careful experiment in grinding rye, (weighing fifty-six pounds per bushel,) that it lost three and a half pounds; and many experiments in grinding grain it lost from one to five pounds per bushel; which loss could not be accounted for any way, better than supposing it to be the escape of fixed air.

In answer to which, I asserted in my first communication that Mr. D. Walton presumed to make it appear than one bushel of grain contained more than one bushel of loose air; and then go on to prove it by the philosophy of D. Blair, which says "that air weighs three hundred and twenty-four grains for every one thousand cubic inches, and that it is nine hundred times lighter than water." I then state that there is two thousand one hundred and fifty and forty-two one hundredths cubic inches in a bushel; therefore, if one thousand cubic inches of air weighs three hundred and twenty-four grains, two thousand one hundred and fifty and forty-two one hundredths cubic inches of air will weigh one ounce nine dwts. but no more; and before he confines more loose air in a bushel of grain than one ounce nine dwts. he will be obliged to employ some artificial power to aid nature in her wonderful and mysterious work of its germination.

In answer to which, Mr. D. Walton says, "the one-tenth which is the lawful toll in this state, with what the millers in this part of the country extract in the process of cleaning, (and that too without the waste of grain,) would amount to more than the tenth part of the original weight of the grain when taken to mill; and until he proves that there is no unavoidable diminution of weight in the grinding of grain, or that it can be attributed to some other cause more certain than the departure of fixed air, my statements remains sound and unrefuted. And further, Martin's philosophy expressly says, that this fixed air as it is roused, expands itself into a million times more space than it filled before in a dense body; or in other words, in the position in which nature placed it "in her wonderful and mysterious works of formation." In answer to which I stated, that I had ground and bolted under my own inspection, two bushels of wheat, weighing one hundred and twenty pounds, and that it lost in the process of grinding one and one-fourth pounds, on the two bushels, which of course, will make a loss of ten ounces on one bushel; and then assert that I do not believe that the average loss in grinding twenty bushels would exceed seven ounces per bushel. Now the mystery is, how to account for this loss. I will account for a part of it in two ways, viz. first, the dampness of the grain is absorbed by the heat caused by the friction of grinding, (which dampness or water, Blair says is nine hundred times heavier than air;) of this fact any person may convince himself by putting his hand up in the top part of the leader that conveys the flour from the stones; he will find it wet and pasted with damp flour; and in the second place, flour coming from the stones, hot and parfectly dry, the finest and dryest of it will rise into the air, there remain until impregnated with its dampness, then settle into every part of the mill. I then say, I consider it much more philosophical to attribute this loss of weight to the dampness, or water contained in the grain, than to suppose, as Mr. D. Walton has, that it is all fixed air. I then wish him to prove that there is more air in any species of grain, than the open portions of said grain will contain of loose air, [or if he prefers the term better, air in its natural, free state]; the only way he can make it appear, is, that the air is condensed, which I will not admit without plain proof. I say it is confined, if there should any appear in the grain, but do not believe it to be condensed. It is folly to assert that there is condensed air in grain; for this reason, before it can be condensed, the grain must diminish to a smaller substance than that from which it originated. Or as I have before stated, if it contains air at its formation, the air has more room as the grain grows; the grain may shrink some from the size it once attained, but before it can condense the air it must shrink to a smaller substance than from which it sprang; it may be argued that the grain receives the air all the time it is growing; if so, the air is not condensed; for that moment the grain begins to shrink, the air will leave it through the same passage it was received. I asserted that I thought he would be disappointed if he expected to convert nine-tenths of the agricultural community to the belief, that the grain they raised is even one-hundreth part air. I will here inform him the number of bushels of loose air, (or air in its free, natural state,) it will take to weigh 1lb., 5lbs. and 12lbs. It will take to weigh one pound or sixteen ounces, eleven bushels and one quart, to weigh five pounds, fifty-five bushels five quarts, to weigh twelve pounds, one hundred thirty-two bushels, twelve quarts; now in the fist place this one pound or eleven bushels, one quart of air, is to occupy a space of only 1-60 part of a bushel, (if it should be wheat weighing 60 pounds per bushel,) for if there is a loss of 1 pound, that is one-sixtieth of a bushel, and if this loss is condensed air, it will take 11 bushels and one quart of loose air to weigh 16 ounces or 1 pound, and provided his loss is 3 1-2 pounds as he has stated it to be, in 56 pounds of rye $\frac{3.5}{56}$ if this loss is fixed air it will measure 38 bushels 19 quarts, and must occupy a space of $\frac{3.5}{56}$ parts of a bushels. As this is my last communition upon this subject, I will observe that I have considered what Mr. Silas Walton has had to say upon this subject, beneath my notice. He has been quoting from Oliver Evens, Martin, and Blair, but is so self conceited, that he thinks their wisdom is nothing compared with his. I will assure him before he confines one-half the quantity of air he wishes to make exist in a bushel of grain, it will explode, and fracture his skull notwithstanding the thickness it appears to be. Respectfully yours, WILLIAM A. STONE.

Attention to Silk recommended.

Shrewsbury, N. J. June 19, 1839.

JUDGE BUEL—Dear Sir—Will you through the medium of your widely extended paper, call the attention of the American people to this one single subject, viz.:—*Growing raw silk in the states for home or foreign market, as an additional resource to the country*, free from a confusion with every other subject which various writers and speakers appear to confound with it; such as *importing silk goods, manufacturing silk goods, the advantages of wearing silk, &c.* My object is to concentrate the public mind to one single subject at once.—The question is not (in my humble opinion,) whether we import twenty-five millions of dollars worth of silk annually, or fifty millions, or none at all, or large amounts in iron, hemp or other staple or fancy articles; for if we imported one hundred millions in silk, and could export to advantage the same amount in the produce of our country, we need not go to raising silk, (or seek any other resource to pay the debt,) or to manufacturing silk to prevent it. But the first grand question is, *Does the whole of our imports exceed our exports? and if so, how much?* In investigating this question, if a balance is found against us, how shall we improve our system of national economy, so as to keep an even account with other nations? My answer is, *increase the resources of the country*, in some way or other, equal to the wants of the people, or such revulsions as the past will be a natural consequence of trading beyond means, and will return again in due time, as sure as the return of summer and winter. If we had a despotic government, the despot might retrench expenses of living, the peasantry could be compelled to dispense with silk, and all other imported goods, both dry and wet; but free trade is the motto of a free people; so retrenchment is out of the power of a free government. A free and sovereign people will eat, drink and wear what they please if they can get it. Now how shall we prepare to pay the balance annually counting against us in Europe, or turn the balance in our own favor? My answer is, go to raising raw silk in the north and west, and on the exhausted cotton and tobacco lands of the south, and add that to the cotton and tobacco of the south, and if the tables are not turned in less than ten years, the American people are not what I take them to be. We want union of effort. It interests the whole community. It would puzzle me to tell which class would be most benefitted by the improvement, the commercial, manufacturing or farming community; or the north, the west or south. In my humble opinion, it would tend to cement the Union, and secure peace at home and abroad; it will make the interest of all of the states more generally one interest; it would be a good backer to our commercial community, and raise and secure their credit abroad, and would tend to facilitate trade, and secure peace with other nations, and especially England, as she could obtain her raw silk of us in trade, and can raise none herself. Now would not raw silk equal in amount to the cotton in the south, be a help to the commercial class in times like the past, and would it not enable the manufacturing class to set their wheels agoing sooner in case of another revulsion? And would it not be a profitable additional branch of farming?—Now, sir, will you give the ideas of an illiterate farmer, (submitted with humble deference,) a proper investigation, and expunge or add what you think proper, and couch the whole in proper language, and lay this single subject fairly and squarely before the American people, and I'll be bound they'll not be slow in seeing their own interest. Yours, &c. LYCURGUS.

EXTRACTS.

On the Selection of Grain Seeds, Roots, &c.

[*From the Mark Lane Express*]

The grand and distinguishing characteristic of plants over inorganic matter—that which characterizes their latent powers and living functions, is their susceptibility of improvement; animals have it to a certain degree, but not nearly to such an extent as plants, for the productive faculty of the former cannot be increased like that of the latter. As is well remarked by Mr. Sharon Turner, most agreeable and surprising transformations have arisen from this property. The rose is the product of cultivation; the original plant from which all our beautiful varieties have proceeded is considered by botanists to have been the common wild briar. Our plums are cultivated decendants of the sloe; the peach and nectarine of the common almond tree; filberts are the improvements of the wild hazel; the delicious apples whose species may now be reckoned by hundreds, are the cultivated successors of the small austere crabs and wildings, which swine will scarcely eat; the original pear is a petty fruit, as hard and crude as the former; our cauliflowers, cabbages, and other domestic vegetables, may be regarded as almost artificial products, so much has human skill had to do in their production.

If then so great a susceptibility of improvement exists in the productions of horticulture, it becomes a question of great interest and momentous importance to ascertain whether or not the different species of grain, roots, and grasses, employed in agriculture are possessed of a like inherent susceptibility. It is a well known fact that grain, if allowed to degenerate, returns into a state very similar to that of some of our coarser grasses, which of itself is a very strong argument as respects the point at issue. But we have still more unequivocal evidence that wheat, even in what may be denominated its present improved state when compared with the inferiority of its supposed original, is possessed of the principle of productiveness to an extent fully as great as the vegetables mentioned in the above quotation. In proof of this, we would refer to the experiments instituted by Colonel Le Couteur on the different varieties of wheat, as fully detailed by him in a valuable pamphlet which we have just perused, and which we would recommend to the careful consideration of every agriculturist. Colonel Le Couteur began seriously to cultivate the important plant of wheat so as to procure the several soils distinct from each other, and at the same time note the experiments made on the culture, produce, weight of the grain, and qualities of the corn, flour and straw. He has kept a most minute account of the experiments, and taken the greatest care to preserve the best sorts in their purity, and the result of his experience is, that he believes the proper mode of cultivation of wheat is yet unknown or unpractised. The Colonel, before he turned his attention to the selection and purification of wheat, considered his crops tolerably pure, yet on Professor Le Gasca, a celebrated botanist, examining them, he selected from them, twenty-three sorts, of which some have since been discovered to be three weeks later in ripening than others, which circumstance accounts for the many shrivelled, ill-grown grains in a sample of wheat, arising no doubt from the unequal growth of the many varieties that link in the purest crop. The importance of ascertaining the qualities of the different varieties of wheat, is well exemplified by Col. Le Couteur in respect to their relative value as to produce of straw. The quantity of straw produced from a single ear of one of his best varieties, No. 1, Jersey Danzig, was 3lb. 3oz. of wheat, and 3lb. 9oz. of straw, only 6oz. more straw than wheat; No. 2, "Album Densum," produced 2lb. 12oz. of wheat and more straw than wheat; No. 5, "Coturaneum," six ounces more straw than grain; and No. 8, "Koelen," 4lbs. 4oz. of wheat and only 3lbs. 13oz. of straw. The next, No. 9, the Red Compact, produced only 2lb. 9oz. of wheat from 3lbs. 15oz. of straw, an excess of one pound six ounces of straw over the grain in this last, whereas the former, No. 8, a most excellent and superior variety, there was an excess in grain of seven ounces over the straw. Col. Le Couteur justly observes, that by a proper system of culture, it must appear obvious from these facts that wheat should be brought to such perfection, as to produce more grain than straw; Nos. 8, 10 and 13, varieties selected and tested by actual practice, having done so. Now by reference to the article "British husbandry" chap.—page 154 of that excellent work, the farmer's series of useful knowledge, we find it stated that "the straw is generally reckoned to be about double the weight of the grain." We believe this may be perfectly correct as far as regards ordinary husbandry, yet if the results obtained by Col. Le Couteur's experiments are of any value, we must conclude that the proper culture of wheat, if known, is unpractised.

These experiments, however, were not confined to the weight or productiveness of the different varieties of wheat; on the contrary the Colonel continued his researches from the straw and grain, on to the meal itself, in order to be fully satisfied which of the sorts under experiment contained the greatest proportion of meal or flour, and the result nearly proved that the most productive sort in grain was also the most farinaceous. A circumstance of a very important nature was elucidated in the progress of these experiments, and proves the comparative advantages to be derived from actual practice, skill, and observation, to that of science alone for the purpose of testing and proving the merits of the different varieties of grain. Professor Le Gasca with all his experience and botanical research, was impressed with the notion, that a variety of No. 14 was one of the most productive, while it was proved by actual experiment to be the most inferior of the fourteen sorts tested, evincing the positive necessity of comparative experiments to ascertain the relative produce of wheat, which the theory alone, even of the learned Professor, could never have discovered, he merely having judged from the external appearance of the wheat, its squareness and compact form; than which, nothing could have proved more deceptive.

We have frequently in the course of these letters inculcated the advantages of a change of seed grain, and the adaption of certain districts for producing the different varieties in greater perfection, than that of others, and we are glad to observe, that Col. Le Couteur arrives at the same conclusion. It indeed must inevitably stand to reason, that the fine white wheat which is grown on a rich fertile loam suitably retentive of moisture, can never be the proper sort to be sown on a poor black soil, such as Bagshot Heath, which of itself is incapable of retaining or attracting moisture. But it will not be denied that if a red or coarse variety, equally productive as to quantity, though perhaps less farinaceous, could be grown on such a soil, it would be an end greatly to be desired, and of much national importance. An observation made by Col. Le. Couteur leads him to believe that such will be the result. In a piece of land which had been ill prepared, and was poor and out of condition, a crop of white wheat had been sown; it scarcely grew three feet in height, but among it was a plant of fine, tall, rich. brown wheat, with a large round, but rather coarse grain. It proved a highly productive variety. Had he happened to have sown the field with all such, instead of having only had twenty bushels per acre, subsequent experience has shown him that he would probably have had forty.

In Colonel Le Couteur's observations on the selection of seed grain, he remarks—"It has frequently puzzled me much to imagine, upon what principle some writers have recommended for seed a sort of inferior grain, the refuse of a crop, after all has been sent to the market. How a principle so entirely contrary to the whole economy of nature could for a moment obtain it is difficult to conceive. For even from the finest of seed, after five years of experiments, I am persuaded that for a crop one-tenth of the best grain perishes, or is destroyed by birds, mice or insects; but from some sorts which looked sickley, and were purposely sown singly, grain by grain, in 1833, I found that a liver-coloured variety which, from the appearance of the ear, promised to be highly productive, though the grains were ill-grown, thirty-three grains out of seventy-two died, which induced me to discard it as being too delicate, its grains being poor and lean, though grown on a rich and well prepared soil. Another variety also from poor ill-fed wheat, lost forty-nine grains out of sixty-two. A sample of golden-drop, which I got at Mark-lane, tolerably well grown, had seven varieties in a handful, and thirty-four of these died out of seventy-two grains. Whereas from other healthy plump grains of several varieties, only nine, ten and twelve died out of seventy-two grains of each variety. In 1834, the "Belle Vue Talavera," was so well grown and plump, that of three rows of seventy-two grains each not one died; of No. 1, Danzig, only three to four in three rows of the same number; and of No. 2, "Album Densum," only eight from the same number died. From one hundred and forty-four grains of a new white Spring Wheat, a very rare, hardy and promising variety, only ten died.

My general observations lead me to believe, that when wheat appears to grow lean and poor looking it should be discarded from the locality, after a fair trial—say after the third year, as the second only might be the result of climate, or the want of being naturalized to the soil. The first trial should be made from seed of the best quality: if this fails after the third year, it is evidently unsuited to the soil and climate, and a new sort should be introduced. It must be obvious that lean and shrivelled wheat is not so likely to nourish the young plant just starting from its embryo state into life, with a mere miserable skin of a parent to live upon, as the fine rich nutriment to be met with in a plump, round, farinaceous grain, full of meal.

The nice discrimination and care requisite to mature a pure and distinct variety of grain, is well exemplified in Colonel Le Couteur's own practice; for in the progress of dibbling out the grains of four ears of wheat which were selected to him by Professor Le Gasca, he remarked a great discrepancy in the grains of each ear; they were not even of the same colour, and differed greatly as to form, some being round, some oval and peaked, some plump but very small, some more elongated, some with the skin or bran much thicker than others; there were also, many with liver-coloured yellow, and dark grains among the white. Colonel Le Couteur therefore recommends the selection of a single grain of a pure and known variety, for the purpose of procuring a sort with a distinct character and of prolific habits; but this subject is so nice, and admits of so many distinctions, that to arrive at this he believes it may be necessary to destroy every female blossom, excepting one, on the plant, which may be selected for impregnation or future experiment; and there can be no doubt that, with due attention, the practice can be established as satisfactorily, as the success that has been met with by those who have attended to the intercrossing of geraniums, now grown of all shades and colours, almost at will.—Indeed, the care which Colonel Le Couteur took in making his selections, and the great number of sorts he found of all shades and colours, forming varieties and sub-varieties, as they were termed by Professor Le Gasca, confirmed him in the opinion that the only chance of having pure sorts was to raise them from single grains or single ears. In reference to this matter, Colonel Le Couteur observes—"It is but fair to add, that even the pains I took in making these first selections amply rewarded my labours, as the produce of my crops was increased from an average of about twenty-three or twenty-five bushels per acre to about thirty-four; and since I have raised wheat from single ears or carefully selected sorts, I have increased my crops to between forty and fifty bushels the acre. Hence I have no doubt, that with extreme care in obtaining the best and most suitable sorts of wheat, that land, in high tilth, with fine cultivation may be made to produce sixty or seventy bushels per acre." Colonel Le Couteur further remarks, that "much has been judiciously written on the growth and cultivation of wheat, which has tended to a material improvement in those farms where care has been taken, perceptible even to superficial observers; but no writer has yet called the attention of the agricultural world to the cultivation of pure sorts, originating from one single grain. It is contended that this has been the root of all the evil; many have attempted to begin well, but few, if any, have thought of commencing from the original, and persevering and keeping it pure. This idea struck the author so powerfully on the first conversation which he had with the Professor Le Gasca, that it has never quitted him. His project was considered visionary and unattainable. Old farmers said, that as no farmer in the world had ever thought of separating and classing wheat it could not be done; it was impossible to get a pure crop! The bees would mix the farina, mice would mix the grain, birds would do the same; if it had been feasible, it would have been tried before. Corn-factors assured him, that the climate of England was not calculated for the growth of such fine skinned wheat as that of Danzig, Volhynia, and Sandomir. Professor Le Gasca alone perceived and approved of the author's project.

The learned Professor had been theoretically employed in the classification and scientific examination of wheat as a plant, in the research and consideration of all its varieties; but it had escaped him to consider it in its properties, with relation to the good of man.—This practical view the author took of it, and he determined to attempt to discover which were the most farinaceous and productive varieties, by comparing their character and produce one with another.

From the foregoing observations we will arrive at the following conclusion, viz.—That the wheat in this country is much mixed, and therefore is rendered less productive than a variety or varieties with distinct characters, distinguished for their suitableness for our different soils and climates, and the practicability of obtaining such varieties is clearly demonstrated in the practice of Colonel Le Couteur. Also, that when we procure a pure and suitable variety of seed wheat it is absolutely necessary to guard against the admixture, and that this can only be accomplished by unremitting care and attention.

It will farther be observed, that it is not enough to select varieties that may appear valuable in the eye of the botanist, but that they must be tested and proved by actual experiment before their merits and qualities can be properly appreciated or understood, and that in fact the want of these practical tests have hitherto proved the root of all the evil.

Lastly, although Colonel Le Couteur has directed his experiments solely to wheat, yet sufficient is known to render it probable that the different seeds and roots at present in cultivation in this country would be susceptible of a like improvement, if subjected to a similar process and the test of experiment.

A SCOTCH FARMER.

On the Nature and Properties of Lime.

Sir H. Davy says, that "quick lime (hydrate of lime) in the pure state, is injurious to plants; that when mixed with moist fibrous vegetable matter, there is a strong action between the lime and the vegetable, and they form a kind of compost of which a part is usually soluble in water; but that carbonate of lime is a useful ingredient in soil, that it acts upon the decomposing vegetable and animal matter in the soil, so as to render it more fitted for the purposes of vegetation, that it prevents the two rapid decomposition of substance already dissolved, but has no tendency to form soluble matter."

Quick lime is a combination of lime with one-third of its weight of water, in which state it is called hydrate of lime; when it is exposed to the atmosphere a sufficient time it reabsorbs from the atmosphere the carbonic acid gas which it lost during the process of burning, and in this state it resumes all the properties it had before it was burnt. This effect is soon produced after it has been slaked and spread on the land in a dry state, and it has very little time in its caustic state of quick lime to effect any alteration on the soil; it must therefore be in its original carbonaceous comminuted state when intimately mixed with the soil, that it can have any effect either on the soil or on the decaying vegetable matter therein.

The effect which it produces on the soil must therefore be as an alterative in changing its texture by the addition of so much carbonate of lime to it in a very finely divided state.

Dr. Anderson and Du Hamel are of the opinion that powdered marble or powdered limestone has a good effect on grass land.

Anderson says, "that lime is no sooner slaked than it immediately begins to absorb its air and return to its former mild state; or in other words, it becomes effete, in which state it possesses the same chemical qualities in every respect as limestone.

"If this be spread out thinly upon the surface of the earth, it absorbs its air in a very short time. A few hours in this situation, restores a large proportion of its air; and in a day or two, at most, it becomes perfectly effete, as masons experience when they sweep together the scattered particles that have lain around their heaps of lime and attempt to use it in mortar by itself, for it is then no more coherent than sand or moistened earth.

"Hence then it must follow, that in every case, lime is converted into the same state with limestone, in a few days after it is mixed with the soil; so that if it produces any effect at all as lime, as a saline substance, it must only be at the very first, when it is applied, and it must act ever afterwards merely as powdered limestone.

"But it is well known, that lime produces scarcely any sensible effect as a manure, at the beginning. Even the first year after it is applied to the soil its effects are inconsiderable, in comparison of what it produces in the second and succeeding years. From whence we must conclude, that it operates upon the soil, merely as a mild calcareous earth; and that its calcination is of no farther utility in preparing it for manure, than as a cheap and efficacious method of reducing the limestone to a fine powder." Other chemists say that it requires exposure to the atmosphere for a considerable time to render it completely effete, or to receive its full quantity of carbonic acid gas. Kames, Young, Brown, and others say, that long experience has convinced them that lime is as efficaceous in its effete as in its caustic state, and Kames thinks it produces little effect on vegetables till it becomes effete; it therefore appears not only from their opinion, but also from the appearance of practical farmers, that the efficacy of lime on some land does not arise from any effect it may produce when in a caustic state, but from those qualities which it possesses in common with all other calcareous matter. It must be evident that lime, in a dry, slaked, or pulverized state, can be more easily and intimately mixed with the soil, than when it becomes wet, and in a state like mortar.

Is lime only a stimulant exerting its influence on something that is already in the soil? and if so, does its influence tend to exhaust this something? or, is it an enriching manure which gives nourishment to plants? or does it, by becoming a portion of the soil, improve its texture and composition by making the soil more capable of supplying the food necessary for the production of vegetables? Dr. Anderson says, "Writers on agriculture have been long in the custom of dividing manure into two classes; viz. enriching manures, or those that tended directly to render the soil more prolific, however sterile it may be. Among the foremost of which was reckoned dung, and exciting manures, or those that were supposed to have a tendency to render the soil more prolific, merely by acting upon those enriching manures that had been formerly in the soil, and giving them a new stimulus, so as to enable them to operate anew upon that soil, which they had formerly fertilized, in which class of stimulating manures, lime was always allowed to hold the foremost rank."

"In consequence of this theory, it would follow that lime could only be of use as a manure, when applied to rich soils; and, when applied to poor soils, would produce hardly any, or even perhaps hurtful effects." "I will frankly acknowledge, that I myself was so far imposed upon by the beauty of this theory, as to be hurried along with the general current of mankind, in the firm persuasion of the truth of this observation; and for many years did not sufficiently advert to those facts that were daily occurring to contradict this theory. I am now, however, firmly convinced, from repeated observations, that lime and other calcareous manures, produce a much greater proportional improvement upon poor soils, than on such as are richer; and that lime alone, upon a poor soil, will, in many cases, produce a much greater and more lasting degree of fertility than dung alone.

"In direct contradiction to the theory, I must add, that I never yet met with a poor soil in its natural state which was not benefitted in a very great degree by calcareous matters when administered in proper quantities.

"But I have met with several rich soils that were fully impregnated with dung, and therefore exactly in that state in which the theory supposes that lime would produce the greatest effect,—but upon which lime, applied in any quantities, produced not the smallest sensible effect."

And again, in another place he says:—"I have often heard it urged, as an objection to the use of lime as a manure, that although it does indeed promote the fertility of a soil, in a higher degree at first, yet, in the end, it renders it much more sterile than formerly.

"This, like many other objections to useful practices, takes its rise entirely from the avarice and unskilfulness of those who complain. It is chiefly heard of in those part of the country, where it is not uncommon for a farmer, after once liming a poor soil, to take fifteen or sixteen crops of oats successively, without any other dressing or alternation of crops. It must be a good manure that enables these soils to produce such a number of successive scourging crops of any sort; but it would be a marvellous one indeed, if it should prevent those fields from being exhausted by them.

"But is it not well known, that in all the richest and best improved parts of the country, lime has been long employed as a manure?—yet so far are these soils from being rendered sterile by it, that it is doubtful if any art, without the assistance of lime or some calcareous matter, could ever have brought these fields to their present degree of fertility. Those, therefore, who complain of the hurtful effects of lime as manure, proclaim what they ought to conceal, that they have had in their possession a treasure, which might have enriched their posterity, but which they have idly squandered away in their own lifetime." Although lime produces a great effect on certain poor land which has been in a state of nature, yet where lime is applied to poor worn out arable land which has been limed and exhausted by severe cropping, it has, from practical experience, no effect whatever.

If lime be a stimulant, there are roots in the soil of poor land in a state of nature for it to act upon; but in poor worn out land exhausted by severe cropping, there are none.

Again, such worn out land may, from the very circumstance of its worn out state, be so loosened, that an application of lime may, as an ingredient in the composition thereof, only tend to increase the evil by making it more loose and friable. Brown says, "It is sufficiently understood, that land which has been long in grass contains much vegetable matter, and that the trouble and expense of liming it would be amply repaid to the cultivator; but the propriety of applying lime on old arable lands, has been questioned, and with much justice, by the most part of practical agriculturists, and their doubts on that head are confirmed by the fullest experience.

"Were lime a manure, it would be a noble substance, for enriching and restoring fertility to lands worn out by a succession of corn crops; but as worn out land is not restored to fertility by the application of lime, we are warranted to consider it in a different light; or, in other words, as an article to bring certain principles into action, previously possessed by the soil. This conclusion is sanctioned by experience; and experience is a far better guide than the most plausible theory.

"When lime duly operates, the whole powers of the soil are put in a state of requisition, and may be forced to act till the very soul of vegetation is extracted. It is scarcely practicable to restore fertility to land, even to the best natural quality, which has been thus abused; at least, a considerable period must elapse before it can be restored to its original fertility; but thin moorish soils after being exhausted by lime, are not to be restored. To lime them a second time, is not only a useless expenditure of labor and money, but also productive of serious mischief. Soils of this description, after a second liming, are apt to singe and burn the grain that is sown upon them; and, even when dunged, not to make such a return as would have been rendered under different circumstances.

"Lime has been long applied by British husbandmen, as a stimulus to the soil; and in consequence of such an application, luxuriant crops have been produced even upon soils of apparently inferior quality, and which would have yielded crops of trifling value had this auxiliary been withheld. In fact, the majority of soils cannot be cultivated with advantage till they are dressed with lime; and whether considered as an alterative, or as a stimulant, or as a manure, it will be found to be the basis of good husbandry, and of more use than all the other manures put together. Wherever lime has been properly applied, it has constantly been found to prove as much superior to dung, as dung is to the rakings of the roads, or the produce of a peat mine.

"From a pretty long experience, and considerable attention to the operation of lime, we are inclined to think that it acts both as an alterative and as a stimulant; operating in the one case as a medicine that changes the nature of the soil, and in the other as arousing or bringing into action the vegetable powers contained in the soil, which without such an application would have remained dormant and inactive. These opinions, we know are different from those maintained by several ingenious men, but they are supported by the result of numerous trials, undertaken to ascertain how and in what measure lime operated upon the soil."

It is evident that lime, when applied to land in however small quantities, will tend to change its texture; and when there is vegetable matter in the soil, it may produce a greater decomposing disposition in it than before. In this case, it will act as a stimulant, hastening the decay of vegetable matter, and thereby furnishing the elements of vegetable life. Lime also acts powerfully on an irony matter in the soil, and on the gravel sands, and clay soils of the diluvial formation; and on the soil of the plastic clay, the new and old red sandstone, and the basaltic formation, the effect produced by the application of lime is very great. This may be owing, as we have said before, to neutralizing the pernicious effects of the sulphate of iron, and converting it into a useful soil; and every fresh application of lime may therefore convert an additional portion of sulphate or oxide of iron into an additional portion of good and useful soil. When there is a deficiency of carbonaceous matter in the soil, a fresh portion of lime must increase the productive powers of the soil.

The effects which lime, as an alterative, has on the soil, must depend in a great measure on the composition of that article, and also on the composition of the soil to which it is to be applied; for the composition of the various limestone formations, and also the chalk and marls, vary greatly. The nature of the ingredients being different, the lime from the silicious limestone contains a considerable portion of silicious particles, and may answer best on stong clay soils, as it will furnish both silicious and calcareous matter to the clay soil; and the lime burnt from the lias limestone, which contains a considerable portion of clay, will produce the best effect on light sandy soils. But there are some soils on which lime when applied, has never produced any beneficial effect. This is the case with the soil on the oolitic formations, and other calcareous soils. This is evidently owing to the superabundance of lime already in the soil, so that an addition of calcareous matter only increases the evil; but where there is no calcareous matter in the soil, and also a great quantity of iron, as is the case in the soil of the new red sandstone formation, the lime has an increased effect on every fresh application. This is so well known in the neighborhood of Taunton in Somersetshire, and over all the soil of the new red sandstone, that the farmers lime their land every time it comes in course of fallow for turnips, and this produces excellent crops even without dung.

It is most astonishing that writers on agriculture have retailed an opinion, that quick lime, when mixed in a mass of earth containing the live roots and seeds of weeds, will destroy them. Any attempt of this kind will meet with a complete failure; for the roots and the seeds of weeds cannot be destroyed by the fermentation or any heat that can be produced in such a compost.—The same writers have also stated that lime hastens the decay of vegetable matter; whereas the fact is, that it retards the process of the decomposition of vegetable matter. If straw of long dung be mixed with slaked lime, it will be preserved, while if mixed with an equal portion of earth, the earth will hasten its decay.

It has been shown that although vegetables are composed of mucilage, starch, sugar, albumen, gluten and various other substances, yet all of them are reducible into carbon, oxygen, and hydrogen; and that water and air are composed of these substances;—that vegetable and animal manures are decomposed into the same elements, as those of water and air;—that any of the simple minerals which compose the surface of the earth, when unmixed with any other mineral, are unfit for the growth of vegetables; but that when these simple materials are intimately mixed together, that this compound when exposed to the influence of the sun and atmosphere, produces an abundant crop;—that there is no process going on at the surface of the earth amongst the materials which compose the cultivated soil which changes any of the mineral component parts of it into a new substance; that none of the materials composing the soil, enter into the composition of the plants;—and that the application of manure does not always cause productiveness in soils.—*Morton on Soils.*

Agriculture.

The following statement of the comparative modes of farming in England and America, is extracted from that amusing publication, *The Clockmaker:*—"The bane of this country, Squire, and, indeed, of all America, is havin' too much land; they run over more ground than they can cultivate, and crop the land so severely that they run it out. A very large portion of land in America has been run out by repeated grain crops; and when you add that to land naturally too poor to bear grain, or too broken for cultivation, you will find this great country in a fair way to be ruined: The state of Vermont has nothin' like the exports it used to have; and a plaguy sight of the young folks came down to Boston to hire out as helps. The two Carolinas and Virginia are covered with places that have been given up as ruined, and many other states. We hav'n't the surplus of wheat and grain we used to have in the U-nited States, and it never will be so plenty again. That's the reason you hear of folk's clearin' land, makin' a farm, and sellin' off again, and goin' further into the bush. They've exhausted it, and find it easier to clear new lands than to restore the old. A great deal of Nova Scotia is run out: and if it war'n't for the lime, marsh-mud, sea-weed, salt sand and what not, they've got here in such quantities, there'd be no cure for it—It takes good farmin' to keep an upland location in order, I tell you, and make it sustain itself. It takes more to fetch a farm too that's had the gizzard taken out of it than it's worth. It actilly frightens me when I think your agriculture in Britain is progressin' and the land better tilled every day, while thousands upon thousands of acres with us are turned into barrens. No traveller as I've seed have noticed this, and our folks are not aware of it themselves to the extent of the evil. Squire, you and I wont live to see it; but, if this awful robbin' of prosperity goes on for another century as it has progressed for the last hundred years, we'll be a nation of paupers. Very little land in America, even of the best, will carry more than one crop of wheat arter its cleared a'fore it wants manure; and where its cleared' so fast, where's the manure to come from, it puzzles me? (and I won't turn my back on any man in the farmin' line;) the Lord knows, for I don't; but if there's a thing that scares me it is this. * * * Yes, too much land is the ruin of us all at this side of the water. Afore I went to England I used to think that the onequal divisions of property there, and the system of landlord and tenant, was a curse to the country; and that there was more dignity and freedom to the individual and more benefit to the nation, for every man to own the land he cultivated, as with us. But I'e changed my mind; I see it's the cause of the high state of cultivation in England, and the prosperity of its agriculture. If the great men had the lands in their own hands there, every now and then an improvident one would skin the soil and run it out; bein' let to others, he can't do it himself, and he takes plaguy good care by his lease his tenant shan't do it neither. Well, then, there he his, with his capital to make great improvements, substantial repairs, and so on, and things are pushed up to perfection."

Young Men's Department.

Self-Culture.

BY W. E. CHANNING, D.D.

(*Continued.*)

I proceed to another important means of self-culture, and this is the control of the animal appetites. To raise the moral and intellectual nature, we must put down the animal. Sensuality is the abyss in which very many souls are plunged and lost. Among the most prosperous classes, what a vast amount of intellectual life is drowned in luxurious excesses. It is one great curse of wealth, that it is used to pamper the senses; and among the poorer classes, though luxury is wanting, yet a gross feeding often prevails, under which the spirit is whelmed. It is a sad sight to walk through our streets, and to see how many countenances bear marks of a lethargy and a brutal coarseness, induced by unrestrained indulgence. Whoever would cultivate the soul, must restrain the appetite. I am not an advocate for the doctrine, that animal food was not meant for man; but that this is used among us to excess, that as a people we should gain much in cheerfulness, activity, and buoyancy of mind, by less gross and stimulating food, I am strongly inclined to believe. Above all, let me urge on those, who would bring out and elevate their higher nature, to abstain from the use of spirituous liquors. This bad habit is distinguished from all others by the ravages it makes on the reason, the intellect; and this effect is produced to a mournful extent, even when drunkenness is escaped. Not a few men, called temperate, and who have thought themselves such, have learned, on abstaining from the use of ardent spirits, that for years their minds had been clouded, impaired by moderate drinking, without their suspecting the injury. Multitudes in this city are bereft of half their intellectual energy, by a degree of indulgence which passes for innocent. Of all the foes of the working class, this is the deadliest. Nothing has done more to keep down this class, to destroy their self-respect, to rob them of their just influence in the community, to render profitless the means of improvement within their reach, than the use of ardent spirits as a drink. They are called on to withstand this practice, as they regard their honor, and would take their just place in society. They are under solemn obligations to give their sanction to every effort for its suppression. They ought to regard as their worst enemies, (though unintentionally such,) as the enemies of their rights, dignity, and influence, the men who desire to flood city and country with distilled poison. I lately visited a flourishing village, and on expressing to one of the respected inhabitants the pleasure I felt in witnessing so many signs of progress, he replied, that one of the causes of the prosperity I witnessed, was the disuse of ardent spirits by the people. And this reformation we may be assured wrought something higher than outward prosperity. In almost every family so improved, we cannot doubt that the capacities of the parent for intellectual and moral improvement were enlarged, and the means of education made more effectual to the child. I call on working men to take hold of the cause of temperance as peculiarly *their* cause. These remarks are the more needed, in consequence of the efforts made far and wide, to annul at the present moment a recent law for the suppression of the sale of ardent spirits in such quantities as favor intemperance. I know, that there are intelligent and good men, who believe, that, in enacting this law, government transcended its limits, left its true path, and established a precedent for legislative interference with all our pursuits and pleasures. No one here looks more jealously on government than myself. But I maintain, that this is a case which stands by itself, which can be confounded with no other, and on which government from its very nature and end is peculiarly bound to act. Let it never be forgotten, that the great end of government, its highest functions, is, not to make roads, grant charters, originate improvements, but to prevent or repress crimes against individual rights and social order. For this end it ordains a penal code, erects prisons, and inflicts fearful punishments. Now if it be true, that a vast proportion of the crimes, which government is instituted to prevent and repress, have their origin in the use of ardent spirits; if our poor-houses, work-houses, jails and penitentiaries are tenanted in a great degree by those, whose first and chief impulse to crime came from the distillery and dram-shop; if murder and theft, the most fearful outrages on property and life, are most frequently the issues and consummation of intemperance, is not government bound to restrain by legislation the vending of the stimulus to these terrible social wrongs? Is government never to act as a parent, never to remove the causes or occasions of wrong doing? Has it but one instrument for repressing crime, namely, public, infamous punishment, an evil only inferior to crime? Is government a usurper, does it wander beyond its sphere, by imposing restraints on an article, which does no imaginable good, which can plead no benefit conferred on body or mind, which unfits the citizen for the discharge of his duty to his country, and which, above all, stirs up men to the perpetration of most of the crimes, from which it is the highest and most solemn office of government to protect society?

I come now to another important measure of self-culture, and this is, intercourse with superior minds. I have insisted on our own activity as essential to our progress; but we were not made to live or advance alone. Society is as needful to us as air or food. A child doomed to utter loneliness, growing up without sight or sound of human beings, would not put forth equal power with many brutes; and a man, never brought into contact with minds superior to his own, will probably run one and the same dull round of thought and action to the end of life.

It is chiefly through books that we enjoy intercourse with superior minds, and these invaluable means of communication are in the reach of all. In the best books, great men talk to us, give us their most precious thoughts, and pour their souls into ours. God be thanked for books. They are the voices of the distant and the dead, and make us heirs of the spiritual life of past ages. Books are the true levellers. They give to all, who will faithfully use them, the society, the spiritual presence of the best and greatest of our race. No matter how poor I am. No matter though the prosperous of my own time will not enter my obscure dwelling. If the sacred writers will enter and take up their abode under my roof, if Milton will cross my threshold to sing to me of Paradise, and Shakespeare to open to me the worlds of imagination and the workings of the human heart, and Franklin to enrich me with his practical wisdom, I shall not pine for want of intellectual companionship, and I may become a cultivated man though excluded from what is called the best society in the place where I live.

To make this means of culture effectual, a man must select good books, such as have been written by right-minded and strong-minded men, real thinkers, who instead of diluting by repetition what others say, have something to say for themselves, and write to give relief to full earnest souls; and these works must not be skimmed over for amusement, but read with fixed attention and a reverential love of truth. In selecting books, we may be aided much by those who have studied more than ourselves. But, after all, it is best to be determined in this particular a good deal by our own tastes.—The best books for a man are not always those which the wise recommend, but oftener those which meet the peculiar wants, the natural thirst of his mind, and therefore awaken interest and rivet thought. And here it may be well to observe, not only in regard to books but in other respects, that self-culture must vary with the individual. All means do not equally suit us all. A man must unfold himself freely, and should respect the peculiar gifts or biasses by which nature has distinguished him from others. Self-culture does not demand the sacrifice of individuality. It does not regularly apply an established machinery, for the sake of torturing every man into one rigid shape called perfection. As the human countenance, with the same features in us all, is diversified without end in the race, and is never the same in any two individuals, so the human soul, with the same grand powers and laws, expands into an infinite variety of forms, and would be wofully stinted by modes of culture requiring all men to learn the same lesson or to bend to the same rules.

I know how hard it is to some men, especially to those who spend much time in manual labor, to fix attention on books. Let them strive to overcome the difficulty, by choosing subjects of deep interest, or by reading in company with those whom they love. Nothing can supply the place of books. They are cheering or soothing companions in solitude, illness, affliction. The wealth of both continents would be no equivalent for the good they impart. Let every man, if possible, gather some good books under his roof, and obtain access for himself and family to some social library. Almost any luxury should be sacrificed to this.

One of the very interesting features of our times, is the multiplication of books, and their distribution through all conditions of society. At a small expense, a man can now possess himself of the most precious treasures of English literature. Books, once confined to a few by their costliness, are now accessible to the multitude; and in this way a change of habits is going on in society, highly favorable to the culture of the people. Instead of depending on casual rumor and loose conversation for most of their knowledge and objects of thought; instead of forming their judgments in crowds, and receiving their chief excitement from the voice of neighbors, men are now learning to study and reflect alone, to follow out subjects continuously, to determine for themselves what shall engage their minds, and to call to their aid the knowledge, original views, and reasonings of men of all countries and ages; and the results must be, a deliberateness and independence of judgment, and a thoroughness and extent of information, unknown in former times. The diffusion of these silent teachers, books, through the whole community, is to work greater effects than artillery, machinery, and legislation. Its peaceful agency is to supersede stormy revolutions. The culture, which it is to spread, whilst an unspeakable good to the individual, is also to become the stability of nations.

Another important means of self-culture, is to free ourselves from the power of human opinion and example, except as far as this is sanctioned by our own deliberate judgment. We are all prone to keep the level of those we live with, to repeat their words, and dress our minds as well as bodies after their fashion; and hence the spiritless tameness of our characters and lives.—Our greatest danger, is not from the grossly wicked around us, but from the worldly, unreflecting multitude, who are borne along as a stream by foreign impulse, and bear us along with them. Even the influence of superior minds may harm us, by bowing us to servile acquiescence and damping our spiritual activity. The great use of intercourse with other minds, is to stir up our own, to whet our appetite for truth, to carry our thoughts beyond their old tracks. We need connexions with greater thinkers to make us thinkers too. One of the chief arts of self-culture, is to unite the childlike teachableness, which gratefully welcomes light from every human being who can give it, with manly resistance of opinions however current, of influences however generally revered, which do not approve themselves to our deliberate judgment. You ought indeed patiently and conscientiously to strengthen your reason by other men's intelligence, but you must not prostrate it before them. Especially if there springs up within you any view of God's word or universe, any sentiment or aspiration, which seems to you of a higher order than what you meet abroad, give reverent heed to it; inquire into it earnestly, solemnly. Do not trust it blindly, for it may be an illusion; but it may be the Divinity moving within you, a new revelation, not supernatural but still most precious, of truth or duty; and if after inquiry it so appear, then let no clamor, or scorn, or desertion turn you from it. Be true to your own highest convictions. Intimations from our own souls of something more perfect than others teach, if faithfully followed, give us a consciousness of spiritual force and progress, never experienced by the vulgar of high life or low life, who march, as they are drilled, to the step of their times.

Some, I know, will wonder, that I should think the mass of the people capable of such intimations and glimpses of truth, as I have just supposed. These are commonly thought to be the prerogative of men of genius, who seem to be born to give law to the minds of the multitude. Undoubtedly nature has her nobility, and sends forth a few to be eminently "lights of the world." But it is also true that a portion of the same divine fire is given to all; for the many could not receive with a loving reverence the quickening influences of the few, were there not essentially the same spiritual life in both.—The minds of the multitude are not masses of passive matter, created to receive impressions unresistingly from abroad. They are not wholly shaped by foreign instruction; but have a native force, a spring of thought in themselves. Even the child's mind outruns its lessons, and overflows in questionings which bring the wisest to a stand. Even the child starts the great problems, which philosophy has labored to solve for ages. But on this subject I cannot now enlarge. Let me only say, that the power of original thought is particularly manifested in those, who thirst for progress, who are bent on unfolding their whole nature. A man who wakes up to the consciousness of having been created for progress and perfection, looks with new eyes on himself and on the world in which he lives. This great truth stirs the soul from its depths, breaks up old associations of ideas, and establishes new ones, just as a mighty agent of chemistry, brought into contact with natural substances, dissolves the old affinities which had bound their particles together, and arranges them anew. This truth particularly aids us to penetrate the mysteries of human life. By revealing to us the end of our being, it helps us to comprehend more and more the wonderful, the infinite system, to which we belong. A man in the common walks of life, who has faith in perfection, in the unfolding of the human spirit, as the great purpose of God, possesses more the secret of the universe, perceives more the harmonies or mutual adaptations of the world without and the world within him, is a wiser interpreter of Providence, and reads nobler lessons of duty in the events which pass before him, than the profoundest philosopher who wants this grand central truth. Thus illuminations, inward suggestions, are not confined to a favored few, but visit all who devote themselves to a generous self-culture.

Another means of self-culture may be found by every man in his condition or occupation, be it what it may. Had I time, I might go through all conditions of life, from the most conspicuous to the most obscure, and might show how each furnishes continual aids to improvement. But I will take one example, and that is, of a man living by manual labor. This may be made the means of self-culture. For instance, in almost all labor, a man exchanges his strength for an equivalent in the form of wages, purchase-money, or some other product. In other words, labor is a system of contracts, bargains, imposing mutual obligations. Now the man, who, in working, no matter in what way, strives perpetually to fulfil his obligations thoroughly, to do his whole work faithfully, to be honest not because honesty is the best policy, but for the sake of justice, and that he may render to every man his due, such a laborer is continually building up in himself one of the greatest principles of morality and religion. Every blow on the anvil, on the earth, or whatever material he works upon, contributes something to the perfection of his nature.

Nor is this all. Labor is a school of benevolence as well as justice. A man to support himself must serve others. He must do or produce something for their comfort or gratification. This is one of the beautiful ordinations of Providence, that, to get a living, a man must be useful. Now this usefulness ought to be an end in his labor as truly as to earn his living. He ought to think of the benefit of those he works for, as well as of his own; and in so doing, in desiring amidst his sweat and toil to serve others as well as himself, he is exercising and growing in benevolence, as truly as if he were distributing bounty with a large hand to the poor. Such a motive hallows and dignifies the commonest pursuit. It is strange, that laboring men do not think more of the vast usefulness of their toils, and take a benevolent pleasure in them on this account. This beautiful city, with its houses, furniture, markets, public walks, and numberless accommodations, has grown up under the hands of artizans and other laborers, and ought they not to take a disinterested joy in their work? One would think, that a carpenter or mason, on passing a house which he had reared, would say to himself, "this work of mine is giving comfort and enjoyment every day and hour to a family, and will continue to be a kindly shelter, a domestic gathering-place, an abode of affection, for a century or more after I sleep in the dust;" and ought not a generous satisfaction to spring up at the thought? It is by thus interweaving goodness with common labors, that we give it strength and make it a habit of the soul.

There is one circumstance attending all conditions of life, which may and ought to be turned to the use of self-culture. Every condition, be it what it may, has hardships, hazards, pains. We try to escape them; we pine for a sheltered lot, for a smooth path, for cheering friends, and unbroken success. But Providence ordains storms, disasters, hostilities, sufferings; and the great question, whether we shall live to any purpose or not, whether we shall grow strong in mind and heart, or be weak and pitiable, depends on nothing so much as on our use of these adverse circumstances. Outward evils are designed to school our passions, and to rouse our faculties and virtues into intenser action. Sometimes they seem to create new powers. Difficulty is the element, and resistance the true work of a man. Self-culture never goes on so fast, as when embarrassed circumstances, the opposition of men or the elements, unexpected changes of the times, or other forms of suffering, instead of disheartening, throw us on our inward resources, turn us for strength to God, clear up to us the great purpose of life, and inspire calm resolution. No greatness or goodness is worth much, unless tried in these fires.—Hardships are not on this account to be sought for. They come fast enough of themselves, and we are in more danger of sinking under, than of needing them. But when God sends them, they are noble means of self-culture, and as such, let us meet and bear them cheerfully. Thus all parts of our condition may be pressed into the service of self-improvement.

I have time to consider but one more means of self-culture. We find it in our Free Government, in our Political relations and duties. It is a great benefit of free institutions, that they do much to awaken and keep in action a nation's mimd. We are told, that the education of the multitude is necessary to the support of a republic; but it is equally true, that a republic is a powerful means of educating the multitude. It is the people's University. In a free state, solemn responsibilities are imposed on every citizen; great subjects are to be discussed; great interests to be decided. The individual is called to determine measures affecting the well-being of millions and the destinies of posterity. He must consider not only the internal relations of his native land, but its connexion with foreign states, and judge of a policy which touches the whole civilized world. He is called by his participation in the national sovereignty, to cherish public spirit, a regard to the general weal. A man who purposes to discharge faithfully these obligations, is carrying on a generous self-culture. The great public questions, which divide opinion around him and provoke earnest discussion, of necessity invigorate his intellect, and accustom him to look beyond himself. He grows up to a robustness, force, enlargement of mind, unknown under despotic rule.

It may be said that I am describing what free institutions ought to do for the character of the individual, not their actual effects; and the objection, I must own, is too true. Our institutions do not cultivate us, as they might and should; and the chief cause of the failure is plain. It is the strength of party spirit; and so blighting is its influence, so fatal to self-culture, that I feel myself bound to warn every man against it, who has any desire of improvement. I do not tell you it will destroy your country. It wages a worse war against yourselves. Truth, justice, candor, fair dealing, sound judgment, self-control, and kind affections are its natural and perpetual prey.

I do not say, that you must take no side in politics. The parties which prevail around you differ in character, principles, and spirit, though far less than the exaggeration of passion affirms; and, as far as conscience allows, a man should support that, which he thinks best. In one respect, however, all parties agree. They all foster that pestilent spirit, which I now condemn. In all of them, party spirit rages. Associate men together for a common cause, be it good or bad, and array against them a body resolutely pledged to an opposite interest, and a new passion, quite distinct from the original sentiment which brought them together, a fierce fiery zeal, consisting chiefly of aversion to those who differ from them, is roused within them into fearful activity. Human nature seems incapable of a stronger, more unrelenting passion. It is hard enough for an individual, when contending all alone for an interest or an opinion, to keep down his pride, wilfulness, love of victory, anger and other personal feelings. But let him join a multitude in the same warfare, and, without singular self-control, he receives into his single breast the vehemence, obstinacy and vindictiveness of all. The triumph of his party becomes immeasurably dearer to him than the principle, true or false, which was the original ground of division. The conflict becomes a struggle not for principle but for power, for victory; and the desperateness, the wickedness of such struggles, is the great burden of history. In truth, it matters little what men divide about, whether it be a foot of land or precedence in a procession. Let them but begin to fight for it, and self-will, ill-will, the rage for victory, the dread of mortification and defeat, make the trifle as weighty as a matter of life and death. The Greek or Eastern empire was shaken to its foundation by parties, which differed only about the merits of charioteers at the amphitheatre. Party spirit is singularly hostile to moral independence. A man, in proportion as he drinks into it, sees, hears, judges by the senses and understandings of his party. He surrenders the freedom of a man, the right of using and speaking his own mind, and echoes the applauses or maledictions, with which the leaders or passionate partizans see fit that the country should ring. On all points parties are to be distrusted; but on no one so much as on the character of opponents. These, if you may trust what you hear, are always men without principle or truth, devoured by selfishness, and thirsting for their own elevation, though on their country's ruin. When I was young, I was accustomed to hear pronounced with abhorrence, almost with execration, the names of men, who are now hailed by their former foes as the champions of grand principles and as worthy of the highest public trusts. This lesson of early experience, which later years have corroborated, will never be forgotten.

Of our present political divisions I have of course nothing to say. But among the current topics of party, there are certain accusations and recriminations, grounded on differences of social condition, which seems to me so unfriendly to the improvement of individuals and the community, that I ask the privilege of giving them a moment's notice. On one side we are told, that the rich are disposed to trample on the poor; and on the other, that the poor look with evil eye and hostile purpose on the possessions of the rich. These outcries seem to me alike devoid of truth and alike demoralizing. As for the rich, who constitute but a handful of our population, who possess not one peculiar privilege, and, what is more, who possess comparatively little of the property of the country, it is wonderful, that they should be objects of alarm. The vast and ever-growing property of this country, where is it? Locked up in a few hands? hoarded in a few strong boxes? It is diffused like the atmosphere, and almost as variable, changing hands with the seasons, shifting from rich to poor, not by the violence but by the industry and skill of the latter class. The wealth of the rich is as a drop in the ocean; and it is a well known fact, that those men among us, who are noted for their opulence, exert hardly any political power on the community. That the rich do their whole duty; that they adopt the great object of the social state, which is the elevation of the people in intelligence, character, and condition, cannot be pretended; but that they feel for the physical sufferings of their brethren, that they stretch out liberal hands for the succor of the poor and for the support of useful public institutions, cannot be denied. Among them are admirable specimens of humanity. There is no warrant for holding them up to suspicion as the people's foes.

Nor do I regard as less calumnious the outcry against the working classes, as if they were aiming at the subversion of property. When we think of the general condition and character of this part of our population, when we recollect, that they were born and have lived amidst schools and churches, that they have been brought up to profitable industry, that they enjoy many of the accommodations of life, that most of them hold a measure of property and are hoping for more, that they possess unprecedented means of bettering their lot, that they are bound to comfortable homes by strong domestic affections, that they are able to give their children an education which places within their reach the prizes of the social state, that they are trained to the habits, and familiarized to the advantages of a high civilization; when we recollect these things, can we imagine that they are so insanely blind to their interests, so deaf to the calls of justice and religion, so profligately thoughtless of the peace and safety of their families, as to be prepared to make a wreck of social order, for the sake of dividing among themselves the spoils of the rich, which would not support the community for a month. Undoubtedly there is insecurity in all stages of society, and so there must be, until communities shall be regenerated by a higher culture, reaching and quickening all classes of the people; but there is not, I believe, a spot on earth, where property is safer than here, because, nowhere else is it so equally and righteously diffused. In aristocracies, where wealth exists in enormous masses, which have been entailed for ages by a partial legislation on a favored few, and where the multitude, after the sleep of ages, are waking up to intelligence, to self-respect, and to a knowledge of their rights, property is exposed to shocks which are not to be dreaded among ourselves. Here indeed as elsewhere, among the less prosperous members of the community, there are disappointed, desperate men, ripe for tumult and civil strife; but it is also true, that the most striking and honorable distinction of this country is to be found in the intelligence, character and condition of the great working class. To me it seems, that the great danger to property here is not from the laborer, but from those who are making haste to be rich. For example, in this commonwealth, no act has been thought by the alarmists or the conservatives so subversive of the rights of property, as a recent law. authorizing a company to construct a free bridge, in the immediate neighborhood of another, which had been chartered by a former legislature, and which had been erected in the expectation of an exclusive right. And with whom did this alleged assault on property originate? With levellers? with needy laborers? with men bent on the prostration of the rich? No; but with men of business, who were anxious to push a more lucrative trade. Again, what occurrence among us has been so suited to destroy confidence, and to stir up the people against the moneyed class, as the late criminal mismanagement of some of our banking institutions. And whence came this? from the rich or the poor? from the agrarian, or the man of business? Who, let me ask, carry on the work of spoliation most extensively in society? Is not more property wrested from its owners by rash or dishonest failures, than by professed highwaymen and thieves? Have not a few unprincipled speculators sometimes inflicted wider wrongs and sufferings, than all the tenants of a state prison? Thus property is in more danger from those who are aspiring after wealth, than from those who live by the sweat of their brow. I do not believe, however, that the institution is in serious danger from either. All the advances of society, industry, useful arts, commerce, knowledge, jurisprudence, fraternal union, and practical Christianity, are so many hedges round honestly acquired wealth, so many barriers against revolutionary violence and rapacity. Let us not torture ourselves with idle alarms, and still more let us not inflame ourselves against one another by mutual calumnies. Let not class array itself against class, where all have a common interest. One way of provoking men to crime is to suspect them of criminal designs. We do not secure our property against the poor, by accusing them of schemes of universal robbery; nor render the rich better friends of the community, by fixing on them the brand of hostility to the people. Of all parties, those founded on different social conditions are the most pernicious; and in no country on earth are they so groundless as in our own. *(To be continued.)*

THE N. YORK AND LONG-ISLAND SILK GROWING AND MANUFACTURING COMPANY.—This company has been formed for the purposes which its title indicates. Its capital is $60,000, divided into shares of $10 each, most of which having been subscribed, the company will shortly go into operation. Books of subscription for the remaining shares will be opened on and after the 30th of April, at the undermentioned places, where the prospectus may be had and every information obtained.

G. C. THORBURN, No. 11 John-street.
ALONZO WAKEMAN, office of the Am. Institute, No. 179 Broadway.
J. W. WEAVER & Co. No. 79 Barclay-st.

N. B. Persons at a distance wishing to subscribe to the above, can do so by forwarding 20 per cent on each share, (post-paid,) to GEO. C. THORBURN, treasurer. 1t

WATKINS' PATENT WHEAT FANS, GRAIN CRADLES, and every other variety of tool required for harvesting, for sale by R. SINCLAIR & Co.
July–2t Baltimore, Md.

AGRICULTURAL WAREHOUSE and SEED STORE, 79 Barclay-street, New-York. At this old established stand, the subscribers take pleasure in announcing to the public, that they have made extensive arrangements to accommodate farmers in all articles connected with husbandry, viz:—Agricultural implements, a full and fresh supply of Field and Garden Seeds, Fruit Trees, Durham Cattle, Chinese and Berkshire pigs, 10,000 morus multicaulis mulberry trees, publications on rural subjects, &c.

Published here, the Rural Library, S. Fleet, editor; a few copies of 1st vol. for sale. The object of this work is to constitute a library at the least possible expense. 2d vol. commencing with Prof. Low's Elements of Practical Agriculture, with nearly 250 fine engravings; subscription $3. Subscriptions received for the Genesee Farmer, Cultivator, &c.
July–3t J. W. WEAVER & Co. 79 Barclay-st. N.Y.

THOROUGH-BRED IMPROVED SHORT-HORN CATTLE.—The subscriber has recently taken charge of the superior stock of Short-Horn Cattle, bred by L. F. Allen. Esq. on his farm at Grand-Island, in the Niagara river. The original stock from which these have been produced, were selected from among the best animals in the country, and several of them were imported direct from England. As a milking stock, the cows of this herd will challenge competition with those of any other in the United States; several of them being extraordinary milkers, and all of them good. For the making of butter, they have been thoroughly tested, and their dairy excellence is remarkable. Their value in this particular, is fully sustained in the grade animals descended from the bulls of this herd, which have, thus far, without exception, proved the best of milkers. This excellence, possessed in reality by no cow so much as in the pure Short-Horn, has been too much neglected by both English and American breeders, and their value as a dairy stock thus underrated.

In addition to the above, are a select herd of DEVON SHORT-HORNS, bred from two choice pure Devon cows, directly descended from the celebrated herd of Mr. Coke, of Holkham, Eng. These beautiful animals are a cross of different degrees with the pure "Improved Short-Horns," without any admixture of common blood; and are as perfect combinations of excellence in color, hardihood, symmetry and size as can be found.

As the present herd, of all ages, has now attained the number desirable to be kept on the farm, (upwards of forty,) a part of them are offered for sale. Application may be made either personally or by letter, (post-paid,) to SAMUEL ALLEN, Esq. at Black-Rock, N. Y. or to the subscriber on the farm, five miles below, at which a ferry connects with the main shore, on the Erie canal. LEWIS G. COLLINS.
Grand-Island, May 15, 1839.
P. S. A few fine grade animals also for sale. jtf.

FOR SALE—A Splendid Country Seat in the Highlands, on the Hudson River. That beautiful country residence, known by the name of the BEVERLY ESTATE, containing four hundred acres of land, about two hundred of which are fine level arable soil, of an excellent quality, in a good state of cultivation, and not surpassed by any on the river for fertility; the remainder is fine and thrifty timber land. The situation is the most eligible on the Hudson, extending one mile and a half on the river, with a bold shore and convenient dock, nearly opposite West-Point, and within fifty miles of New-York. The prospect is extensive and diversified, reaching from St. Anthony's Peak on the south, to the bay and city of Newburgh on the north. This estate can conveniently be divided into three farms, giving an equal proportion of front on the river, and of arable and timber land to each. Almost every enclosure is supplied with living springs of the purest water. There is on said estate a plain house, (formerly the head-quarters of Gen. Arnold;) also out-houses necessary to carry on the business of the farm. The single fact that during the whole time the cholera raged throughout the state, not one case occurred within ten miles of this place, is sufficient to prove the unrivalled salubrity of the situation. The facilities of intercourse with the city, that can be reached in four hours, by means of numerous steam-boats, are great, and daily increasing, both as regards pleasure, and the convenience of a near market for produce of every description.

For conditions of sale, apply to STEPHEN A. HALSEY, 189 Water-street, New-York, or RICHARD D. ARDEN, on the adjoining farm. Ardenia, 23d April, 1839. j6t

FOR SALE—A splendid Farm, in the town of Hillsdale, Columbia county, N. Y. situated 18 miles east of the city of Hudson, containing about 208 acres of first rate land, about 180 of which is fine level arable soil, of an excellent quality, in a good state of cultivation, and on a very public road from New-York to Albany, and not surpassed by any in Columbia, for fertility; the remainder in fine timber; about 30 acres of good pine and chestnut timber. This situation is the most splended in the town of Hillsdale. The farm can conveniently be divided in to two farms, giving an equal quantity of timber land to each. There is a beautiful grove of fruit and ornamental trees about the main dwelling; also three other DWELLING-HOUSES, three Barns, besides Hay Barns and Barracks, Sheds, &c. Also, out-houses of almost every description, and in first rate order.

Also—Several lots of land in the counties of Broome and Tioga. Terms of payment made to suit the purchaser. Inquire of the subscriber on the premises.
July–2t BARENT WAGER, Hillsdale.

*Moneys received between the 20th May and 24th June, in sums of $5 and over. The total receipts are included from post-offices marked with an asterisk.**

TO IMPROVE THE SOIL AND THE MIND.

Look out for another Panic.

The New-York Times gives the following statement of the amount of duties paid in the district of N. York, during the first quarter of 1838, and the first quarter of 1839:

1838,	$2,407,755 78
1839,	4,309,500 21
Difference,	$1,901,744 43

Now, if we assume this as a criterion for the three coming quarters of the year, it will give an aggregate of $7,606,972.72, as the amount of duties upon foreign importations, paid in the district of New-York, in 1839, over and above what was paid upon the like importations in 1838. This immense sum of seven and a half millions of dollars, the reader will bear in mind, is not the *cost* of the foreign articles we import, but merely the *duty* which is exacted by our laws on their introduction into our country. And if we consider that almost every foreign article not coming in competition with our own manufactures, is imported duty free; and that many other articles pay merely a nominal duty, we may with safety assume, that the duties payable at the custom-house do not amount to more than one-tenth of the cost of the foreign merchandize imported. We arrive, then, at this result, that the foreign goods imported into New-York during the present year, will exceed in amount the importations of 1838, SEVENTY-SIX MILLIONS OF DOLLARS!!!

And who is to foot the bill?—who is to pay the balance? Here is an extra charge against us, in a single port, of seventy-six millions of dollars, in a great measure for articles which we can either produce within ourselves, or do without. We may boast of this as an era of *commercial prosperity*—we may boast that it fills the coffers of our national treasury—but we cannot conceal the apprehension, that it is pregnant with future and direful evils to our country; that it is the prelude to another commercial panic, more dreadful in its effects than the one from which we are just recovering. Really, we are getting commercially mad. Like the reckless spendthrift, we are cumbering our patrimonial inheritance, entailing upon our posterity a ruinous debt, and compromiting our independence as a nation, from a vain ostentation of buying what we do not want, or what at all events we are unable to pay for.

We repeat the question—By whom and how is this seventy-six millions of dollars to be paid? Paid it must be, if we would sustain our character for honesty and fair dealing. The total amount of our exports is but a little over one hundred millions—some millions less than our imports of last year; and according to the data we have assumed, they are likely to fall short of the imports of the current year from fifty to a hundred millions of dollars. Our state stocks have, to the amount of one hundred and seventy millions, been already sent abroad towards paying old balances; some considerable portion of our bank stock has been employed for a like purpose; and, abstracting the exports of cotton, exclusively the production of the south, our exportations will not pay a tithe of the rapidly accumulating debt.

What does this state of things augur to our manufacturing and agricultural interests? This seventy-six millions of foreign merchandize has and will be spread over our country, and must and will be sold, though at a sacrifice to the holders; and supplant, in no small degree, the sales of domestic goods. Our manufacturers will consequently become cramped; their business will be contracted; many mills be stopped, and many failures ensue. The evils to the agriculturist will be, the loss of the market, to the manufacturer, of his provisions and raw materials, a diminution in their price, and a participation in the evils of another commercial panic.

Our anticipations may not be realized; yet the facts upon which they are founded, are such as should put every prudent man on his guard—as should render him cautious of running in debt, particularly for foreign merchandize, and as should induce him, in all cases where it is practicable without a great sacrifice, to give a preference to domestic over foreign productions. The patriots of our revolution could forego the use of foreign goods, and their wives and daughters the use of their favorite beverage, tea, for their country's good. The sons surely have not so degenerated, as to be unwilling to adopt, in part, to *maintain* their independence, that policy which their fathers employed to *achieve* it.

Academies and High Schools.

From the school returns of Massachusetts, it would seem that the tendency of academies and high schools, in the towns where they are established, has been seriously to impair the patronage, and lessen the benefits of the common schools, by compelling the districts, for want of funds, to employ inferior teachers at small salaries. "Where established," says the secretary of the board of education, "private schools and academies tend strongly to diminish the annual appropriations for common schools; they draw their ablest recruits from the common schools, and by being able to offer a higher compensation, they have a pre-emptive right to the best qualified teachers; while simultaneously the district schools are reduced in length, deteriorated in quality, and to the same extent bereft of talents competent for their instruction."

The same influence upon the character and usefulness of our common schools is felt in New-York, from the rapid increase of academics and select schools among us. These *high* schools are patronized and supported by the wealthy; and the effect is not only to withdraw their *patronage* from the common schools; but, what is of perhaps greater consequence, their *care* and *influence* also. And it has become a serious question, whether the character and usefulness of our academies are not impaired by an unreasonable multiplication of them—whether more good, to the pupils and the public, would not result from half than from the whole of them. They are designed to teach classical literature, science and the higher branches of an English education; but their multiplied numbers has so divided and cut up the public patronage, that even with the aid of the literature fund, but a small portion of them are able to obtain the library, the apparatus, or the teachers, which are necessary to carry out the objects of the establishment. The consequence is, that their teachings are more in name than in substance; with this further disadvantage, that as they profess to give higher qualifications of usefulness to the pupils than common schools, and are considered the exclusive avenues to the learned professions—to fame and fortune, they absolutely spoil many boys, by inflating without enriching their minds, who otherwise might have been more useful and more respectable, in the more humble, but not less honorable, employments of life.

Let us not be understood as wishing to disparage the higher branches of learning which are taught in classical schools. We are the avowed and decided advocate of the higher studies. But we would not teach them exclusively to the few, to the prejudice of the many. We would not unnecessarily multiply academies for the professions, already overstocked, to the prejudice of common schools, which are more particularly for the farming and mechanical classes. We would not pull down the high, but we would raise the humble to their level, by giving them those attainments which would serve to improve their condition in business and society. There is not a doubt in our minds, that the teachings of the higher branches of education, embracing the principles of natural science, chemistry and mechanics, would be of far more service to the community, if taught and applied to the arts of productive labor, than they can be to the learned professions.

Under this view of the subject, we consider Secretary Mann correct in saying, that high schools and academies, when multiplied to the extent they now are, are injurious to the cause of common school education. Were the patronage and influence which are now given to the high schools, brought to co-operate with the patronage and influence exerted in the school districts, and the munificent appropriations of the legislature, for competent teachers and district libraries, we have not a doubt that many of our common schools might be raised, in character, to the common standard of academies, and greatly to excel many of the latter in usefulness—because their benefits would be imparted to a whole community, to the producing, as well as to the non-producing classes. It is a principle which cannot too often be inculcated, that the prosperity and happiness of the individual, depends materially upon the intelligence, industry and thrift of the district.

Horticultural Report.

Report of the second exhibition of the Horticultural Association of the Valley of the Hudson.

The second semi-annual exhibition of the Horticultural Society of the Valley of the Hudson was held at Stanwix Hall, Albany, on the 25th and 26th of June.

The committee could scarcely have been more fortunate in the selection of a suitable exhibition room, as the lofty domical apartment, measuring 70 feet from the floor to the ceiling, and of corresponding width, when filled with fine exotics, plants, fine fruits and beautiful flowers, redolent with delightful odors, from the gardens of many of the members, afforded a truly charming *coup d' œil* to the eye of the spectator.

On entering the hall, the rich groups of verdure which encircled it, composed of the most beautiful exotics, afforded the finest possible back ground to central tables, where the numberless bouquets of choice cut flowers and the finest specimens of early fruit were exhibited. One side of the apartment was devoted to the display of the many excellent and well grown vegetables. One hundred and forty superb bouquets of cut flowers decorated the chandeliers, the columns, and various other parts of the room; and during the second day of the exhibition the numerous company of visitors assembled were entertained with the performances of a fine band of music. The middle of the central table was occupied by a beautiful "*Temple of Flora,*" from the Albany Nursery, the floor of which was paved with dahlias and other fine flowers, the columns enwreathed with a variety of phloxes, and the dome covered with a rich variety of roses and Paisley pinks. Among the most striking of the fine greenhouse plants, were some magnificent Roman myrtles, orange and lemon trees, with a great variety of other fine specimens from the Manor House, Albany, which were kindly contributed by Mrs. S. Van Rensselaer. We also noticed a very large specimen of yucca gloriosa, 10 feet high, with equally fine specimens of the India rubber tree, (ficus elastica,) fuchsia gracilis and protea argentea. The oriental cypress of the Levant, the nandina domestica of China, and the fragrant jasmines of the south of Europe, were also conspicuous for their size and beauty. An admirable variety of fine vegetables was contributed by the horticulturists of the counties bordering the Hudson, as well as from the neighborhood of Albany. Gentlemen distinguished for their zeal in horticultural and rural improvement were present from nine of the different river counties, all of whom expressed the warmest interest in the future prospects and success of the society. The early period at which the first semi-annual exhibition is held, necessarily prevents a large show of fruits, the autumnal exhibition being more especially devoted to pomology; but the cherries, strawberries and melons sent were highly deserving commendation.

At the meeting of the members, on the evening of the 25th, the annual election of officers of the association took place; when, the former president declining a re-election, the Hon. EDWARD P. LIVINGSTON, of Clermont, Dutchess co. was chosen president; A. J. DOWNING, Esq. of Newburgh, corresponding secretary; THEODORE ALLEN, Esq. of Hyde Park, recording secretary; and WM. THORBURN, Esq. of Albany, treasurer. A vice-president was also elected for every county on the river, and executive committees for each place where it is proposed to hold exhibitions.

The next autumnal exhibition of the association will be held in New-York on the 12th day of September next, when contributions are solicited from every section of the Valley of the Hudson.

CONTRIBUTIONS TO THE EXHIBITION.

From Mrs. S. Van Rensselaer, Manor House, Albany.—Euphorbia splendens, protea argentea, 8 feet high, lagerstræmia indica, diosma encoides, ericas, several fine species, ficus macrophylla, ficus elastica, daphne variegata, several beautiful geraniums; a number of fine large orange trees loaded with fruit of different varieties; jasminum of different sorts, a large century aloe, yucca gloriosa, fuchsia gracilis, calceolarias, splendid myrtles, &c. &c.—all in pots. Also, several beautiful bouquets of cut flowers, roses, pinks, &c. also a basket of ripe melons, the finest cucumbers, two varieties of strawberries, very large gooseberries, &c. All these were of the finest description, and reflect credit upon Mr. Leonard, the gardener at the Manor House.

Jas. Wilson, Albany.—Luxumburgh moss rose, scarlet moss-rose, white do., village maid do., La Furturelle do., Wellington do., two varieties new petunias, twelve varieties fine heart's ease, a splendid plant of Fuchsia Globosa, and a fine new South American calceolaria, in full bloom; one large orange tree, loaded with fruit, with many other greenhouse plants, and blooms of the following dahlias:—purple perfection, globe white, liberty, Durant's invincible, rose imperialis.

E. Holbrook, Hyde Park.—Bishop's orange strawberries, 4¾ inches in circumference; Keen's seedling and Hautboy's do. all of large size; white smith, crown bob, rifleman, and other gooseberries, extra fine; four fine heads cauliflower, eight do. early York cabbage, Newcastle, early and Egyptian kidney potatoes, fine ripe tomatoes, red top turnips, large early carrots, blood beets, and a fine bouquet of cut flowers.

Josiah Williams, Poughkeepsie.—Two cucumbers, 21 inches in length.

J. Buel & Co., Albany Nursery.—A beautiful variety of fine roses, pinks, &c. tastefully interwoven in the form of a temple of Flora. Also, a great number of plants, in pots, among which the following geraniums, in full bloom, were conspicuous, viz: Mary Queen of Scots, Dennis' Perfection, Macranthon, Droivede, Juliet, Lafayette, Wheelerii Americanum, Adelina, Teativanium, Ferronia, Capt. Cook, &c. &c. Also, a great variety of cut flowers, among which were splendid specimens of the different Chinese Peonias, double white, blush and rose scented. Fine specimens, in pots, of Sollya heterophylla, Lantana Selloroii, Fuchsia Thomsonii, Nerium Splendens, Crassula Coccinea, Cytisus, Argentea variegata, Erica, many species; Bouvardia triphylla, Myrtus flore pleno. Also, 12 stalks giant rhubarb, which weighed (without the leaves) 12¼ lbs.

Edward P. Livingston, Clermont.—Extra fine ripe melons; six very beautiful lemons. Fine specimens of the white oxheart cherry, with a beautiful bouquet, composed in part, of superb carnations, scarlet zinnias, and fine varieties of roses.

Theodore Allen, Hyde Park.—Extra fine gooseberries and cauliflowers, stalks of rye, eight feet long, and a variety of fine vegetables, consisting of lettuce, rhubarb, potatoes, turnips, beans and fine melons.

Messrs. *Downing*, Botanic Nurseries, Newburgh.—Specimens of the following cherries, viz: Yellow Spanish, China Heart, Black Tartarian, Downers late Red, American Heart and transparent. Also, a variety of fine hardy Roses, among which were Pallagi, Village Maid, Chatelaine, George the Fourth, La Cerisette, Diantheflora, Princess Louise, Felicite Perpelaette, Madame Despres, Moss of Moss, Hybrid Blanc, Roi des Hybrides, &c. A beautiful specimen of Amaryllis, with eight fully expanded flowers; bouquets of Verbena Tweediana and T. Major, Datura Arborea; several sorts of Pansy, and cut specimens of the following Geraniums, viz: Dennis' Perfection, Speculum Mundi, Miller's Adonis, Sir John Broughton, Queen of Pixies, &c. Dahlias:—Conqueror of Europe and Lilac Perfection.

Dr. Wendell, Albany.—A fine Fig Tree, eight feet high; Aucuba Japonica, and several varieties of Geraniums, in pots; four fine Cucumbers.

J. R. Stuyvesant, Hyde Park.—Very fine Cauliflowers; also, excellent specimens of early Potatoes, Beans, Cabbage and Tomatoes, with a fine bouquet of cut Flowers.

Mr. Fowler, Albany.—A few select Dahlias, with several bouquets of cut Flowers, Verbena Tweedinana and Ranunclus Marigold.

Mrs. Forsyth, Albany.—A beautiful bouquet of Roses.

Alderman Peters, Newtown, Long Island.—Fine White Heart Cherries.

Mr. Duane, Schenectady Co.—Prairie Grass, from the Mohawk Flats, 8 feet 2 inches high.

Francis Bloodgood, Albany.—Methven Strawberries, four inches in circumference; Green Peas and Cucumbers.

J. P. De Wint, Fishkill Landing.—Extra fine Mayduke Cherries and some fine early Beans.

Thos. Turner, Albany.—A bouquet of beautiful Dahlias and Moss Roses.

Chas. Gilchrist, Albany.—A specimen of Archduke Cherries, beautiful Dahlias, and other cut Flowers, and six Cucumbers.

Alex. Walsh, Lansingburgh.—A table of Silk Worms feeding; Filberts, of last year's growth; Sea Kale, Keen's Seedling Strawberries, Duke Cherries, early Potatoes and Cucumbers, Mushrooms, Seedless Barberry, and a variety of cut Flowers, among which were Paisley Pinks, Feathered Hyacinths, Delphinium Grandiflorum, Campanula Persifolia pl., Spirea Filipendula pl., Hoya Carnosa, Aconitum Napellus, &c. Vegetables—Potatoes, fine Cucumbers, Early York Cabbage and Turnips, with a specimen of a new fodder plant, called 'Esparsette.'

A. P. Heartt, Troy.—Plants in pots, new prolific Lime, Myrtle Orange and Sweet Orange, all in fruit; also, a splendid variety of cut Flowers, Roses, &c. &c.

George W. Warren, Troy.—Three fine Lemons, in pots.

Wm. Thorburn, Albany.—Three seven years' Pumpkins, grown in 1837, perfectly sound; also, some fine Paisley Pinks, in pots; seeds for sale by him.

John B. Hudson, Albany.—Six Heads very large Early York Cabbage, and some beautiful Heads of Sicily Lettuce.

John Crawford, New Scotland.—Stalks of Rye, eight feet one inch in length.

T. McBride, Albany.—A dish of large White Smith Gooseberries.

J. Whalon, Albany.—Fine Lettuce and Cucumbers.

Theo. Roessle, Albany.—One bunch Celery, one do Onions, four Heads Lettuce, and a wreath of Double Curled Parsley.

Alderman Bancroft, Albany.—Fine specimens of Wax Flowers, executed by his daughters.

Sidney Chapin, Albany.—A fine Pine Apple, growing upon its natural stalk.

The Society cordially invite all persons resident in the Valley of the Hudson, who feel an interest in the improvement of our Horticulture, to contribute specimens of Fruits, Vegetables, Flowers, and farm products of every description, to the Autumnal Exhibition to be held on the 12th of September next, in the city of New-York.

A. J. DOWNING, *Corresponding Sec'y.*
Newburgh, Orange county.

Agricultural Education.

This subject underwent an animated discussion in an agricultural meeting in Kent, (England,) in April.—The object of the meeting was to provide means for establishing an agricultural college in that county. The plan is, to raise £15,000, or about $66,000, by shares of £10 each, which is to be applied to the purchase of eight or ten acres of land, and erecting and fitting up a school and other requisite buildings for 300 or 400 young men. A contiguous farm of 600 or 800 acres is to be taken upon a long lease, and stocked, for experiments and practical operations in husbandry. It is proposed to employ nine teachers and other requisite officers; to board and educate young men at 25 guineas a year; and it is estimated that, after paying rent on the farm, salaries and contingent expenses, there will be a surplus of 450 or £500 per annum.

In the discussions which the subject underwent, B. F. Duppa, Esq. remarked as follows—

" In presenting myself for the purpose of explaining a plan for an agricultural college, I do so with more confidence, in consequence of that plan not only being generally approved but revised and added to by many of the chief agriculturists in this country; and it is a singular and important fact, that a want of the knowledge which it is proposed should be imparted there, is admitted in the strongest terms, chiefly by those whose acknowledged success in the practice of agriculture would point them out as living evidences, that no such institution was required. *Of all the occupations in which men engage for the purpose of gaining a livelihood by the application of capital, there is not one in which a large and varied stock of accurate knowledge is not only desirable, but so absolutely necessary, for obtaining the greatest return, as in farming.* The operations which a farmer has to perform, are not few and unvarying, as are those of the manufacturer, who, having once taken up his ground with prudence, proceeds, hot and cold, wet and dry, snow and frost, in the same manner; his machinery or tackling is the same throughout the whole year—it is confined to one spot, performs the same operations, and works upon the same materials, upon which its action always produces the same effects. The produce or the crop of the manufacturer is thus certain; and he only shares with the farmer in the variations of the market. But these are not the only points in which the manufacturers have the advantage; they live together in towns, so that whatever new invention is made, whatever improvement in process is discovered, all learn and adopt it simultaneously, or nearly so. This is not the case with the farmer; he necessarily lives apart—his occupation prevents him seeing much beyond what he does himself—so that it is only through hearsay and reading that successful experiments become known to him. Other counties can be rarely visited, while other countries can be scarcely so at all. The Belgians have made great strides in the practical improvement of agriculture, but how many persons are there in this room who have been to see what they have done? Belgium is but a few hours' voyage from Dover, and a rail-road transports the traveller from one part of the kingdom to another. Such are some of the difficulties of the farmer's position; what arrangements have been made to enable him to overcome them? Agricultural socities have been formed, at which there are exhibitions of produce, prizes are distributed, and ploughing matches take place. But much good as they have done, and are calculated to do, they go not to the root of the evil. No reward—no prize can bring more out of a man than he has in him. We want something which will sink deeper than this, something which will place into the minds and habits of people that which we desire to come out. The only thing I know of capable of effecting this, is an education well adapted to the circumstances and future prospects of the individual. And this, from all I can learn, and the farmers themselves have been my informants, it is impossible now to obtain. But are the manufacturers, who I have shown from their position to stand less in need of science than the agriculturists—are they idle on this head? have they been doing nothing? In most of the large manufacturing towns throughout the kingdom, great efforts are making to give knowledge a bearing upon the principles of the occupation of the place, not only to the manufacturer, but to the mechanic. At Manchester, at Liverpool, at Glasgow, at Edinburgh, in the potteries, in the mines of Cornwall, there are classes for mathematics, chemistry, mechanical drawing and mechanics. They teach the strength and strain of materials, pressure on embankments, floating, engineering, and all matters which the wants and occupations of the locality make desirable; and of the school of arts in Edinburgh, a certificate is given to all pupils who have passed through the mathematical, mechanical and chemical classes, and at an examination shown that they have duly profited. Thus these portions of the population are pushing forward, and while they are doing so, are we men of Kent to remain behind? God forbid! I rejoice from my heart at the exertions making elsewhere. It is only another reason to exert ourselves, if our own improvement, and the increased produce of the soil, are not of themselves of sufficient reward to hold forth. With a view then of enabling the yeomen and others connected with agriculture in this country, to give a superior and suitable education to their children, it is proposed to found a college of agriculture, by the united strength of the county, which shall be so constituted as to afford all the facilities for the religious, moral and intellectual training of a well conducted school, combined with the practical knowledge, practical skill, and the habit of close industry and attention, which can only be obtained upon a farm and in suitable work-shops."

" When the pupils have perfected themselves in the elementary branches of an English education, they will proceed directly," continues Mr. D. " to those departments which bear immediately upon their future professions; and these must be principally chemistry, mechanics, the philosophy of animals and plants,—all as applied to agriculture. In chemistry lies the secret of the manner in which manures act upon different soils, and soils upon each other. In mechanics lies the secret of economizing power of every description. In the physiology of animals and physiology of plants, lie the secrets of choosing and treating animals.—While in the physiology of plants lie the secrets of generating and rearing plants in the greatest perfection, and placing them in soils suitable to their respective natures. Besides intellectual instruction, it is proposed to endeavor to effect two other things, to give our young pupils skill and the habits of industry. It is proposed that they shall be practised in such of the arts as are subservient to agriculture; as carpentry, smith's work, building, surveying, draining and irrigating; that from an early period of life the boys shall be trained to the practical application of what they learn; and that while a portion of the day is devoted to the school room, another will be given to the work-shop, the garden and the field. It is scarcely possible to calculate the effect which such skill possessed by the farmer would have upon the whole race of artizans throughout the country districts. No farmer who could himself use the tools of the carpenter—no farmer who could himself shoe a horse in a proper manner,—would tolerate what was clumsy and unworkmanlike in the carpenter and the smith. The farmers would know what was right, and would have it done. * * * As for difficulties, there are difficulties in the way of everything that is worth attaining. Let us not shrink from them, but meet them fairly, and depend upon it they will yield to us."

" The Rev. W. L. Rham observed, that he had been requested to state to the meeting, what he had observed in similar institutions on the continent, and their effects upon the improvement of agriculture wherever they had been established. In England we had had for a long time little or no communication with the continent, and our farmers were entirely unacquainted with the improvements which had been made in other countries. But this was not the case on the continent. By means of institutions, chiefly supported by the government, where agriculture was taught in theory as well as practice, every work which appeared in England, of any value was examined, and if it contained any practical improvement in the mode of tilling the land, was immediately translated and distributed in a cheap form. In Austria, a book containing the elementary principles of agriculture, is, by command of the emperor, taught in every parochial school—as a subject useful and interesting to every class of men, whether practically engaged in the cultivation of the soil or not. In Prussia the establishment of an agricultural college at Moegelin, on the Oder, had been the means of training a great number of men in the best practices of agriculture; and while they learned to hold the plough, and to observe minutely its action, they had sufficient opportunity to discover defects, and suggest improvements where they were practicable. M. Von Thaer, who was long at the head of this institution, wrote a most valuable work on husbandry, which has been read and translated into almost every language; but for want of institutions in this country which directed men to every source of agricultural knowledge, it has never been translated into English, and till lately, was scarcely known. It is called 'Principles of Rational Husbandry.' The pupils of the school of Moegelin have been dispersed through the country, and have greatly improved the agriculture of Prussia. In Switzerland a school for training young men in a knowledge of practical and improved husbandry, has been established at Hoffwyl, near Bern, by a well known and justly celebrated individual, M. de Fellenburgh. Here general education is combined with agricultural instruction; and this institution is remarkable by having been established and maintained by an individual, without any assistance, excepting some trifling advances by the government of Berne, which have probably been replaced in a very short time. The labor of the pupils amply repays the expense of their maintenance and instruction. * * There is a celebrated school of agriculture at Roville, not far from Nancy, in France, where M. de Dombastles trains young men in the theory and practice of agriculture; and these, afterwards dispersed through the country, introduce improved practices, and will soon raise the agriculture of France to a level with that of the most improved countries; for it must be acknowledged, that, in consequence of the wars and revolutions which have for so many years distracted that fine country, agriculture has been wofully neglected, and was not to be compared with that of the surrounding countries."

" Sir W. B. Riddell eloquently supported the project, and stated that Lord Mensham, himself, Mr. Brett and Mr. Tuffnel, having joined Mr. Duppa, with a view to assist his arduous exertions, communications had been held with some of the first persons in the county, who had unanimously approved of such an institution, together with all persons interested in agriculture who had been consulted. The hon. baronet then read and referred to letters from the archbishop of Canterbury, the bishop of Rochester, Lord Bexley, Viscount Sidney, and Lord Sondes, who all concurred in their approval of such an institution. Earl Spencer, who is president of the British Agricultural Association, Lord Weston, Earl Brecknock, Lord Radnor, Duke of Richmond, Lord Chichester, Earl Winchelsea, and the Marquis of Lansdown, had also expressed their conviction of the utility of some such institution as was then proposed, as also had Mr. Lake, Mr. Bapchild, and several other eminent agriculturists.—Looking as he did to the immense number of persons who were interested in supporting it, in order to procure a suitable education for their children, not only in this but other counties, and even other countries; considering the number of persons, of all conditions of life, who are now sending their sons out to the colonies, he could not entertain a doubt of the success of the Kent Agricultural college."

" Mr. Brett called the attention of the meeting to the fact on which they were all agreed, viz: that there could be no doubt of the lamentable deficiency that existed of facilities for procuring scientific agricultural information. A perfect remedy for that deficiency was offered by this institution. A very large number of gentlemen had consented to take shares in the undertaking; indeed, raising the money was the smallest difficulty they had to contend with. It had been determined that this institution should not be dependent on persons of high station, property and influence; but should be supported by the yeomanry, and all persons connected with agriculture; and the proposed committee, whose duty it would be to prepare estimates, and lay them before a general meeting, contained a preponderant number of yeomen, being formed of twenty-five yeomen, fifteen other persons, five magistrates and five clergymen. At present the subscription list had been confined to Kent; but if it were desirable, many other gentlemen were anxious to support the proposed institution."

We ask of the reader an attentive perusal of the preceding extracts, and particularly those who wish to have sons educated in the principles and practice of an enlightened and improved agriculture. The subject is one of common interest to every class of the community; and although the sentiments here expressed come from "the men of Kent," they nevertheless have a general application, and are especially suited to our condition. And we beg our leading men to note the interest which is evinced in Britain by earls, dukes, bishops, lords, and baronets, in promoting the greatest interest of their country—its agriculture; and to ask themselves, if those men do not, by these noble acts, deserve more respect and more honor, than for the titles which they bear. We too have eminent men, who might be equally useful—we have our earls, dukes and lords, if not in name, at least in wealth, talent and influence, who might, if they would, give an impulse to agricultural education, which would speedily change and improve the intellectual, agricultural and social condition of our country, and render them a blessing to future ages. And since it has become fashionable abroad for great men, and the governments, to interest themselves in these matters, we hope to see the fashion followed here. It is almost the only fashion which we can adopt from Europe, that is suited to our republican institutions; and there is none which so eminently combines the *dulce* with the *utile*—the sweet with the useful.

The efforts to improve the condition of the agriculture of Europe, by imparting scientific as well as the best practical instruction to the young agriculturist, have generally emanated from, and have in all cases been ably seconded by the higher orders of society—by men of science, property and influence, and generally aided by the governments. These men all look to the soil, as we ought to view it here, as the great source of national and individual wealth; and that every advance which is made in its improvement adds to the means of their happiness. Land and labor are the great sources of public and private wealth. The more fertility we impart to the one, and the more intelligence we infuse into the other, the greater will be the return they make, and the greater our means of wealth and power. For it is wealth, rightly employed, that procures for us the substantial enjoyments of life, and that renders us independent, either as individuals or as a nation. Yet it is not a very few rich men, nor a very few wise men, be the aggregate of wealth and talent ever so great, that give prosperity and greatness to a nation. It is the general diffusion, among a whole people, among the rank and file of society, of property and knowledge, and the industry, enterprise, and independence which they beget, that renders a state truly respectable and great. The character and power of a state depend much upon the knowledge and virtue of the sovereign. The people are here sovereigns; and if we would foster and preserve our civil institutions, we must fit these sovereigns for the high duties which are allotted to them. Let us then endeavor to impart to their labors the light and life of science, and the stimuli of distinction and reward. How much more the appellation of great and good—how much more honorable and enduring the fame,—of those who concentrate their efforts and influence in promoting the welfare of a community—of a *whole* community—in endeavoring to multiply, permanently, the comforts, the virtues (for industry is not only a virtue, but the parent of many virtues)—and the happiness of the human family—than of those who concentrate their efforts in party strife,—who strive to keep down their fellows, and to riot upon the fruits of other's industry.

Change of Food.

There seems to be a natural disposition in man, in the brute, and in the vegetable, to a change or alternation of food, alike conducive to the gratification of the appetite and the promotion of health.

This propensity in man is apparent to all. That a change is conducive to health, is evidenced by the fact, that persons long confined to the same diet are much more liable to disease, than those who indulge in a variety. This is seen in long voyages, and in the army, where men subsist daily upon the same rations. If there is any exception to the rule, it is where the food is of the simplest kind, as the brose of the Scotch, the potatoes of the Irish, or the rice of the people of the tropics.

The general principle being admitted, or that even a change is not prejudicial to health, how important is it to our comfort, and economical in regard to expense, to multiply around us the fruits, vegetables, &c. which are the subjects of garden and field culture; and to select for this purpose the best varieties; and these are undergoing constant increase and improvement, by means of culture and fecundation. Every season brings to our notice new species and new varieties, particularly in garden productions, favorable alike to health and to innocent gratification. The tomato and the rhubarb, both of recent introduction to our gardens, are of this character.

"By means of new varieties," says Bishop, "the produce of our gardens and fields are not only increased in a ten fold degree, but the quality of the produce is increased in a still greater proportion, and the difference between varieties that have sprung from the same species, fit them for different purposes, different soils, situations and climates. Thus in edible plants and fruits, we are supplied with an agreeable change throughout the year, from a difference in varieties that have sprung from the same species. Nothing is more obvious, upon comparing original species with their varieties produced by culture, than that we, by means of the latter, enjoy a vegetable food far preferable to that of our forefathers; and as it is probably beyond the power of man, of cultivation, or of time, to determine the degree of excellence attainable by varieties over the species whence they have sprung, and as that degree is unknown, we are justified in regarding it as progressive, and to consider the production of a good variety as the sign or harbinger of a better."

The disposition of animals to change their food, is evidenced by their habits, and their disposition to pluck a variety of herbage, and to select that which is new to them. That a change is conducive, and indeed indispensable to health, has been proved by repeated experiments. Dogs and other animals, who have been confined to one kind of food, although of a kind naturally suited to their wants, have sickened and died. Sinclair cites a case of the effects of two adjoining pastures,—one containing only white clover, and a patch of orchard grass—and the other stocked with five or six kinds of grass, and among them the orchard grass. In the first, the sheep resorted for a change, to the orchard grass, which they ate to the stump, culms and all; and some time after this was exhausted, many of the sheep became affected with the red water, and some of them died. In the adjoining pasture, in which there were six or eight species of grass, the sheep were wholly exempt from disease. But Sinclair demonstrated by accurate experiment, that a multiplicity of grasses sown together, not only contribute to the health and thrift of the animals depastured upon it, but that the product was greater, considerably, and exceeded that of the best old pasture grounds. From these facts Sinclair and others argue, that we ought, in stocking down our grounds, to avail ourselves of all the grasses that we can procure, and that our soil will nourish. Groom observes, that out of more than 200 grasses suitable to England, only one genus, the rye-grass, has as yet received general culture; and that of 60 species of clover, only three or four have received attention. The presumption is, that many indigenous grasses, which have hitherto escaped the notice of our farmers, would be improved by culture to as great an extent as the wild carrot, parsnip, cabbage, potato, apple, plum, peach, &c.

That the vegetable is improved by a change of food, is not only evidenced by the natural law of alternation, witnessed in forests and in cultivated grounds, but by the improvement which takes place from a change of seed. It has become a well established principle, that a change of seeds, from one soil, and from one district to another, is highly advantageous. We have had this particularly verified in the potato, where foreign seed, of like variety and size as that raised on our farm, produced in the same field, one-third the largest crop. Growing from the same seed, without change, seems to be a sort of vegetable breeding in-and-in. The progeny seems to deteriorate in both cases, and ultimately to become worthless. Upon these principles we should not only recommend an alternation of crops, but a frequent change of seed, to ensure a healthy vegetable constitution and vigorous growth.

Geological Report.

We come now, in our examination of the third geological report, to the communication of Professor Emmons, of the second geological district, embracing the northern portion of the state.

"Considering agriculture," the Professor correctly remarks, "of the first importance to a state or community, we are gratified with every discovery which favors its prosecution and increases its products and profits.

"Next in importance are those which increase the quantity of the raw materials for the use of the arts, the manufacturing of which employs directly or indirectly a large portion of the human family. Upon the abundant and cheap supply of those materials, much depends for the prosecution of the great system of internal improvements, the profits and success of which are, in a great degree, dependent on the geological surveys now in progress.

"Last, though not the least in importance, are those discoveries of a scientific nature, which form the data on which natural phenomena are explained, and which constitute the basis on which may be founded the early history of the earth."

Porcelain clay, and *feldspar*, which are essential materials in all the finer kinds of pottery, or what is usually termed China ware, or porcelain, are found in this district; the porcelain clay in Athol and Johnsburgh, in Warren, and in Minerva, in Essex. The Professor expresses a high opinion of the quality of this clay, and his opinion seems to have been confirmed by Mr. Henderson, of Jersey city, an able artist, and a manufacturer of Liverpool ware.

Marble of different kinds and qualities is found in the second district. We extract the notice of the remarkable quarry at Glen's-Falls.

"One of the most valuable quarries which has been opened is at Glen's-Falls. Nature at this place has exposed the strata in such a way that the whole thickness of the limestone can be examined without the labor of artificial or expensive mining. The river has cut into the rock to the depth of at least 70 feet.

"The marble is extensively manufactured by two enterprising companies; it is therefore favorably known to the public, and has acquired a high reputation. For this reason it would be superfluous for me to give a particular account of its qualities. I take the liberty, however, to subjoin a letter which I have recently received from the agent of the Glen's-Falls company, in relation to the position of the marble in the quarry, and also of the quantity which has been manufactured, &c.

"The Hudson river at Glen's-Falls has worn a passage through the limerock to a vast depth, rising in some places seventy feet from its surface. The strata measure from one inch to ten feet. A short distance from the river, on the Saratoga side, lying on limestone, is found black slate. Succeeding this are found strata of marble; slabs have been sawed and used for fire-places. It is sound, and of good colour. Succeeding this on both sides of the river, are found fifty strata of limestone, composed in part of organic remains. Next in succession are found strata of gray marble, two and a half feet thick; it receives a fine polish, but the colour is not admired. A stratum of darker colour follows this which is six inches thick, though valuable only for stepstones. Then follows the black marble, which for brilliancy of polish and beauty of colour, perhaps, has no rival. The whole stratum is ten and a half feet thick. Veins of organic remains run at irregular distances from each other through the strata; these veins are from two to four inches thick, running ten and sometimes twenty feet, break off abruptly. Where these veins do occur, though they are not numerous, they rather mar the beauty of the marble. Who first discovered this marble is not known, and it is of little consequence to inquire. Numerous attempts were made to work it, but without profit, until the present company received it.

"The following exhibits the amount of stone which the Glen's-Falls company have prepared and sent to market during the last four years. The company run sixteen gang of saws, which are equal to about one hundred and sixty single saws.

In 1835, ...	2,157 feet, or	32,000 lbs.
1836, ...	19,800 "	278,500 "
1837, ...	23,400 "	333,900 "
1838, ...	25,000 "	352,500 "

"It is remarked farther by Mr. Roberts, the agent of this company, that the Glen's-Falls marble has gained a good reputation with most of the workers of marble in New-York, Boston and Philadelphia, as it regards its colour, the polish which it receives, and the ease with which it works; and that it is considered equal to any of the kind in this country.

"He states that they have got out shelves for mantles seven feet and six inches long, thirteen inches wide and one and a quarter thick, which sells for sixty-five cents per foot. The price for this kind of stuff has fallen, and at the present is worth from fifty to fifty-five cents per foot; that which is shorter, from thirty to forty."

"There are some considerations in relation to the marble business, which are necessary to be understood by those who are disposed to engage in it.

"1. The expenses of opening the quarry.

"2. The soundness of the layers which it is proposed to work.

"3. Their freedom from hard or flinty particles or masses, as quartz, hornstone, &c.

"4. A sufficient thickness in the several layers composing the bed; for unless there are a number of layers of sufficient thickness to work in juxtaposition, it will be necessary to remove a great mass of useless material. Small defects, such as checks, seams or cracks, or imbedded masses of flint, reduce the value of any piece materially. It is necessary therefore that there should be a general freedom from all the above defects, in order to make it a profitable business."

The species of marble termed *verd antique* is found in Moriah, Warrensburgh, Athol and Johnsburgh, of an excellent quality; and the Professor thinks it may yet form an article of export to Europe, where it is scarce and in great demand.

Peat is found it great quantities. A remarkable growth of it is found on the farm of Mr. Richards, in Warrensburgh, Warren county. It occupies a space of 60 acres, is 60 feet deep, of good quality and of easy access. This material, the Professor remarks, may be applied to four purposes, viz:

"1st. As a manure. To secure or obtain an important result, something more is necessary than simply to spread it upon the soil. It should be raised in the fall, spread in the barn yard, or placed in heaps and mixed with animal matter and lime. Placed under these circumstances it is exposed to the frost and the atmospheric agents, which produce in it incipient chemical changes necessary to convert it into the nutriment of plants. This is especially the case when lime is added to it, which forms a soluble salt, the *geate of lime*, with a portion of the vegetable matter. In the spring it is prepared for removal to the field, and may be spread upon the meadow for grass, or it may be used as a manure for corn, potatoes, &c. It will not answer a good purpose when employed without due preparation, especially when it is spread on meadows for grass; it then becomes dry, is insoluble, and of course unfitted for the nourishment of vegetables. The same remarks might be applied to the preparation of peat as are recommended under the head of preparation of the marly clays.

"2d. Peat, as is well known, answers a good purpose for fuel, and undoubtedly ranks next to coal for sustaining for a long time a high temperature. There is no substance which would remove so much suffering among the poor as the general introduction of this substance for fuel in our larger towns and cities. Its abundance and cheapness recommend it to the attention of the public, and if measures could be devised to bring it into use, in this state, many important results would follow.

"3d. Peat furnishes an abundance of carburetted hydrogen, and hence may be employed for producing gas light. Dr. Lewis Feuchtwanger, of New-York, has made known to the American public the experiments of Merle, a director of a gas light company in France. The advantages of peat for the production of gas are as follows: 1st. It is less expensive than gas from coal, oil or resin. 2d. The produce is nearly as much as from those substances. 3d. The gas is quite harmless and inoffensive, and has, in respect to healthfulness, great advantages over some of the other kinds of gas.

"4th. After it has been employed for gas it may be used for fuel, and it is equal to any charcoal."

As an article of fuel, the Professor thinks peat may be rendered of more value than coal; and he states that it has been advantageously employed in steam-boats, in propelling the engines.

Black lead is found in several localities in Warren and Essex. Several tons have been extracted and marketed.

Application of marls and clays to agricultural purposes.—The Professor's remarks upon this subject are so sound and beneficial, that we copy them entire.

"*Preparation of the marly and tertiary clays.*—In agriculture, as in all kinds of business, many things fall into discredit in consequence of misunderstanding the principle on which their use depends. For instance, the use of plaster on most soils is decidedly beneficial, but there is such a thing as an excessive use of it, and of persevering in its use too long, when its specific effects are imperceptible, and it becomes of no value whatever.

"The due preparation of soil is always an essential matter for the production of a good crop, or to produce a favorable result either in an experimental trial of any new variety of grain, or new mode of culture of those ordinarily raised. It is a matter of common observation, that one farmer succeeds well in his crops, while another does not, though his natural circumstances are equally favorable. Remarks of a similar nature may be made in relation to manures. One succeeds admirably in the use of marl, while another after a little trial, wholly discards it as useless, if not hurtful. This difference of opinion and practice, which is often the result of experiment, is owing to several obvious causes, such as the different modes adopted for securing the end proposed, and which arises from an imperfect or vague notion of the principles by which the desired result is to be produced.

"In the use of the clays, as the common, marly and tertiary, I have found a variety of opinions, each of which, it is pretended, are based on experience. One considers them hurtful, another as useless, while a third finds them, on trial, very useful. It is important to understand how such a diversity of opinions exists, when they are founded on experience.

"I conceive that there are two reasons for this. In the first place, the original character of the soil is such that the use of the clays, under no circumstances, would be proper, or followed with beneficial results. Clay already forms an abundant element in the soil, both for the aliment of the plant, and for the firmness of the soil. In the second place, it is not used in the right state or with due preparation. This leads me to the direct question, What is the right mode of using the clays, or what preparation do they require?

"1st. The great point to be attended to, is to secure a sufficient degree of fineness, that they may be incorporated with the soil, and form, strictly speaking, a constituent part of it. To attain this object, it is necessary that they should be raised in the autumn and placed in heaps, that they be exposed to frost and the atmosphere through the winter. To assist still further in the process of pulverization, it is better to mix them with barn-yard materials, straw, manure, and refuse of any kind, either animal or vegetable. This course being pursued with them, they should be spread as evenly as possible on green sward, that they may enjoy the further benefits of the air, moisture, &c. by direct exposure during the season. Besides, the grass in passing up through the layer will assist greatly in producing a comminuted state. The succeeding season it is in a state to be ploughed in, when it is duly prepared to become a constituent part of the soil; it is only in this way that the stiff and adhesive clays can be broken up and prepared for an incorporation with the other earths.

"Suppose a different course was pursued. Instead of raising the clay in the fall, it was raised and spread immediately in the spring, and ploughed into the soil: the result would be, that it would remain in masses in the earth, and unmixed, in which state it will continue for years with but little change, and instead of being a benefit, it would rather form an annoyance, and incommode both the farmer and his crops. From these remarks, it is clear how two farmers might disagree in their experience with the clays. One, by a suitable preparation of the material, finds a great advantage in their employment; another, by throwing them on or into his soil in lumps, perceives no effect on his crops, or is incommoded by the hard baked masses of clay which a hoe can scarcely divide asunder. It is true, that in time, those masses would disappear, and finally they would become incorporated with the soil, but several seasons would elapse before this would take place, and the result of the trial would be such as to discourage the further employment of the article; besides, I believe that clay or any other material is more readily broken down and pulverized when first taken from the bed than afterwards, when it has been exposed to the hardening influence of the sun during the warm season.

"The necessity of an intimate mixture of any substances intended to act as a manure, cannot be too much inculcated by the agriculturist.

"Most of the clays of this state are those which are marly, or which are combinations of clay and carbonate of lime. They are widely diffused, but their value is not highly appreciated. The time is not distant, however, when they will be esteemed as highly as plaster. They have even one advantage over plaster, that their effects are more lasting when they have had a due preparation.

"The practice of employing vegetable or animal substances in conjunction with marl, or the varieties of calcareous manure, has not prevailed to a suitable extent. It must be plain that carbonate of lime, or sulphate of lime, cannot support vegetation without other materials. It appears, however, that a large proportion of the food of plants exists in the earth in an insoluble state; and that it is by a chemical union of the calcareous matter and this insoluble vegetable substance that it becomes soluble, and fitted for the sustenance of plants in general; hence arises the mutual benefit of combining earths with vegetable and animal substances; and hence, too, the bad practice of continuing the mineral manures until the whole of the vegetable and animal matter is withdrawn from the soil; for by the increased activity of the growing vegetable, the soil is rapidly exhausted of its nutritious matter, and it is left comparatively barren, if the agriculturist ceases to apply vegetable and animal matter. There remains then but one course, that of supplying directly the necessary nutriment; but it is unquestionably better to maintain a sufficiency of vegetable matter always in the earth, and never suffer a soil to be exhausted or worn out by overtaxing its resources."

HAMILTON COUNTY,

Which, until recently, has formed the north part of Montgomery, although broken and mountainous, and as yet but a wilderness, is represented as affording a strong and productive soil, and an excellent country for grazing, raising stock, and for producing butter and cheese. The district comprised in the county of Hamilton is very similar to the Green Mountain range in Connecticut, Massachusetts and Vermont; alike adapted to the raising of fine cattle, and hale, stout, intelligent, independent men, whenever that bane to agricultural and mental improvement—the *lumber business,*—shall cease to be the principal occupation of its inhabitants. The county abounds in lakes and picturesque scenery. Cattle and dairy husbandry have now obtained a firm footing on the northern borders of the Mohawk valley. Farms there are in consequence doubling in value, and the farmers are becoming wealthy; and the proximity of Hamilton county to this district will not permit us to doubt but the example will spread northwardly; and that this new county will ere long attract the notice and the enterprise of the emigrant. The facilities of transporting to market the products of the soil, of the dairy, and domestic animals, hold out advantages to the cultivator which are not to be found in more remote districts. It is an unquestionable fact, that all kinds of animals, including the human species, possess more health, and display finer powers, on the hills and mountains, and in the intervening valleys, than they do on the plains and in the champaign country. Nor is this all—here abide, in their greatest purity, the social and household virtues; and, above all, here liberty loves best to dwell; and it is from the hilly and mountainous districts that she wings her last flight from any and from every land. Driven long since from the plains of Italy, the goddess loves yet to linger in the recesses of the Alps and Appenines, and to hold communion with the descendants of William Tell, and of other patriots of ancient days.

Internal navigation.—By means of the numerous lakes which dot the county, which are nearly upon a level with each other, and most of which are already connected by streams, in part boatable, a channel of internal communication may be opened, at comparatively trifling expense, between the head waters of the Hudson, and the streams which flow into Lake Champlain and the St. Lawrence river. And when we consider that the region abounds in ores, limestone, marble, and the finest timber in the state, it does not require a great stretch of credulity to believe, that the present generation will not pass away ere the county of Hamilton will be in a great part settled, cultivated, and made to develop its resources of wealth and happiness. Lying off from the great thoroughfare of travel, it very seldom attracts the notice of the traveller and the emigrant; and Prof. Emmons has rendered a public service by bringing it out from the shade, in developing its resources, and pointing out the facilities of a water communication, the expense of which will not be much greater, in the end, than a turnpike. to expedite to market the iron, the lumber, the marble, &c. of this extensive district.

CLINTON COUNTY.

This is another county of our state posssessing much good soil, and a climate as mild as its parallel in New-England, which lying off from the great thoroughfares, has not met with the notice from emigrants to which its position and fertility entitle it. It is not only a grazing, but a grain district. The extensive iron and other manufactories within its limits, and upon its borders, will for a long time afford a ready and profitable market for its surplus agricultural products; and when these fail, the lake upon its border affords the ready means of transporting it to Montreal or to Albany, as prices may invite. The agricultural capabilities of this county have in a great measure remained dormant, by reason of the lumber trade, an impediment to improvement which is fast disappearing. Under a better,—under the new system of husbandry, the lake towns may be rendered highly productive in grain, roots and grass,—and those lying in the interior, in cattle and their products. But let us hear the Professor. He says,

"Whoever has travelled during the summer from Port-Kent to the Canada line, along the main road, cannot have failed to remark the excellence of the soil and the favorable make of the country for agricultural purposes. Probably there is no better soil in the state than that of Peru, Chazy and Champlain. It is composed of a due intermixture of the tertiary clays and sands, which nature has sometimes intermingled in the proper proportion to constitute the best for agriculture; in other cases, they are placed in juxta position, prepared to the hand of the husbandman to make that mixture which, in his judgment, shall best promote his interests. Of the richness of the soil, and the favorable nature of the climate, we have an unfailing test, also, in the thrifty growth and healthy state of the apple, and other fruit trees. In a cold soil and a windy district, they are uniformly stinted and covered with parisites, which gives them really a gloomy aspect; but in a good soil and temperate climate, they always look flourishing and green, and free from that sombre appearance they wear when their limbs and twigs are covered by a parasitic growth of lichens."

Sand stone, for glass, *iron ores* and *black marble,* are found in this county. The ores are principally in the southwest section of the county. The iron made from them is of a superior quality.

WARREN COUNTY,

Is strictly a mountainous district; but is sufficiently productive, the report assures us, to answer all the ends of the husbandman. Its mineral productions have already been partially alluded to: and we do not find in the report of this county any suggestions particularly beneficial to agriculture.

Mr. Colman's Second Report.

MANURES.

Under this head the commissioner has given us a short chapter—too short—and has omitted what was most wanted, his own matured opinions. It is a subject of the first importance to agricultural profit. The results which he has cited, of various applications, as gypsum, ashes, marl, &c. serve rather to bewilder than to guide the novice.

The preliminary inquiries in regard to gypsum are, to what soils, and to what crops it is beneficially applied? It certainly operates beneficially upon some soils, and upon some crops; and it is certainly of little or no benefit upon other soils and other crops. For ourselves we are disposed to hold to the theory of Sir Humphrey Davy, till we have a better one to follow; first, because it seems to us the most rational; and secondly, because we think we have found it verified in practice. Davy's opinion was, that gypsum is a necessary element in certain plants; (as a few drops of pepper-mint were wont to be in olden times in a *mint* sling;) that without it, the plant cannot, any more than the sling without the mint, attain its distinctive character, or rather develop its natural volume; that many soils naturally contained enough gypsum to supply the demands of the crop; that other soils were replenished with it in the yard manures which were carried on to them—(the manure containing gypsum)—and that where it did not so exist in the soil, its application would be of certain efficacy to all crops which are found to contain it on analysis. Davy found gypsum in the ashes of clover and lucern, in the ratio of four bushels of this mineral in the crop of an acre. It is a rational philosophical conclusion, that this gypsum must have been derived from the soil; it could not have been imbibed from rains nor from the atmosphere, under any known natural laws;—and the conclusion from these premises is, that unless it had previously existed in the soil, or been artificially supplied, the clover and lucern would have been either diminutive in growth, or deficient in their natural qualities. We do not know what farm crops give gypsum on analysis; but from an experience of twenty years, we have come to the conelusion, that it is beneficial on all *dry* soils, sands, gravels and clays, generally, with the exceptions indicated below, to broad-leaved crops, as clover, lucern, corn, potatoes, peas, beans, buck wheat, &c. and that is of little or no direct service to narrow-leaved plants, as wheat, rye, barley, timothy, &c. It is *not* beneficial in wet grounds, nor within the influence of the marine atmosphere. Its beneficial effects have been greater upon poor soils, especially sandy ones, than upon rich soils, provided the poor soils contained enough organic matters, in a soluble state, to feed the crop. Under this view of the matter, and from the fact that gypsum is not soluble is less than 500 parts of water,—we have adopted the practice, recommended, we think, by Taylor and Peters, of sowing it broadcast upon fields designed for our corn and potatoe crops, before the last ploughing or harrowing, that it might be rendered soluble in due time, by the moisture of the soil; and have scattered it in March or April upon our grass grounds, that it might be carried into the soil by the vernal rains, and be more readily taken up by the roots of the grasses. It is an undisputed fact, that when gypsum is applied late to the surface, and dry weather ensues, it is often inoperative, at least for the season.

One case is cited by the commissioner, of a potato crop, plastered by putting a table spoonful *on the seed in the hill,* giving twice the yield of an adjoining piece which had received no plaster, but in other respects similar treatment with the plastered piece.—This strengthens our theory, and is in conformity with our practice, only that we wet our seed potatoes in the cart, and strew the gypsum upon them there.

The prejudicial effects of ashes are mentioned, when applied to wet soils, as are their beneficial effect upon dry soils. Without being leached, Chaptal remarks, wood ashes are too active; but after having been deprived by the action of water of nearly all their salts, they will produce great effect, particularly upon moist lands and meadows, in which they not only facilitate the growth of useful plants, but if employed for several years they will free the land from weeds and rushes. Wood ashes, he continues, possess the double property of amending a wet and clayey soil, by dividing and drying it, and of promoting vegetation by the salts they contain. Here too we want more light to guide our practice. Ashes do not properly constitute any portion of the positive food of plants. Their efficacy consists in the mechanical amelioration which they afford to the soil, and their chemical effects upon the organic matters, or the materials of vegetable food, which are there deposited. We give to animals condiments and stimulants, to aid the processes of digestion, or at all events some of the human family are in the habit of taking them to excess. These, when duly administered, as the daily use of salt to our farm stock, tend to aid and assist the digestive processes—and to convert the food into healthy chyle, blood and flesh. The soil is the stomach of vegetables; and alteratives and stimuli applied there, are often as beneficial in promoting vegetable nutrition and health, as they are in animal economy. Lime, marl, ashes, gypsum, &c. constitute these alteratives and stimuli. But we lack, though we hope the lacking will not long continue, we lack the same scientific investigations, in regard to the digestive processes of the brute and the vegetable stomachs, that we possess in regard to the digestive processes of the human stomach; before we are able fully to understand the laws which must ever govern in these matters, we must know the constituents of our soils, if we would know what they lack, or what they contain in excess, prejudicial to fertility. We have all the elements of fertility, and the capacity of searching out and applying, and of profiting by them. Industry is enjoined by the holy pen, as one of the principal terms of our temporal happiness.—When applied to the body, it gives us health, and the means of gratifying our animal appetites. When applied to the mind, it lightens the labors of the body, leads to high intellectual enjoyments, and benefits society.

In regard to ashes, the commissioner has failed to note whether they were leached or unleached, or to state in what manner they were applied. Unleached ashes contain potash, an active and powerful fertilizing material upon most soils, if properly applied; and when thus applied they seldom fail to benefit a dry soil. Drawn or leached ashes contain far less of alkali, yet upon some soils they are highly beneficial, particularly upon the seaboard, where their fertilizing properties have been ascribed to the influence upon them of the marine atmosphere, or muriate of soda.

Marl, too, has proved inefficacious in Berkshire; rather, we apprehend, from the imperfect mode of applying it, or from applying it in excess—a shovel full to a hill of potatoes. We have the analysis of the marl thus used. This demonstrates to us the importance of correct punctuation; for according to the text, it contains but 1.2 in 100 of carbonate of lime. It reads and is pointed thus: It contained "of soluble geine 2.6 of insoluble, 3.4 of phosphate of lime, 1.2 of carbonate of lime, 86.2 of granitic sand, 5.0 of water of absorption 1.6." This reminds us of a notice once sent to the pulpit. It was read thus: "A man having gone to sea his wife, desires the prayers of the congregation." The mistake was in placing the comma after *wife*, instead of putting it after *sea*. The comma, in the commissioners report, has given to his *marl* 86.2 of granitic sand, and but 1.2 of carbonate of lime.

But with regard to the application of marl, great errors have prevailed—exposure to atmospheric influence, in a pulverized form, and afterwards a thorough intermixture with the soil, seem to be indispensable requisites to its beneficial operation. See notice of Prof. Emmons' report, in another column.

Having thus made, we fear, too long a chapter, out of Mr. Colman's too short one, we proceed to notice his remarks upon

FARM BUILDINGS,

In which we deem our brother Yankees generally deficient, both as regards economy, comfort, and taste. The commissioner noticed but one stone house in Berkshire, where the best materials, in stone, lime and sand, abound for their construction; though he intimates that they may be constructed cheaper than wood. A substantial stone fabric, with a basement kitchen and window shutters, is twice as economical, in the end, where the materials abound, as a wooden one, and ten times more comfortable. And we would have the roof project, as recommended by our correspondent Mr. Ashburner, four to six feet beyond the walls. We have seen such houses in Ulster, which have stood more than a century, *nearly as good as new*. Stone houses are the warmest in winter, coolest in summer, least liable to take fire; and if well ventilated in summer mornings, and the shutters closed during the day, the apartments are always healthy and agreeable, and free from flies and musquitoes, two formidable enemies to the *siesta*, or after-dinner repose.

The commissioner, like our thriving Dutch farmers, seems to have regarded barns with more interest than he does dwelling-houses; and really, after all, barns are the best criterion of the character of a farming community. Where these are capacious, well filled, and in good order, the dwelling, though small, is seldom out of order, or the family in want of the necessaries and comforts of life. The commissioner recommends that barns be constructed on the sides of hills, that teams may be driven in above, and the manure sheltered from the weather below. We should prefer the Pennsylvanian mode of using the basement story for farm stock; and of depositing the manure in a concave yard, which would hold the liquids, and become a depository for the refuse litter. Dung, and especially horse dung, is apt to become fire-fanged, and seriously injured by being deposited in a dry place in mass. And if in the yard, blended with the dung of neat cattle and litter, no injurious fermentation, or wastage, would take place before it would be wanted for the hoed crops, and to which it is always best applied.

> "In Lanesboro'," says the report, "in one of the neatest establishments which I ever witnessed, there was a little contrivance connected with the doors, the convenience of which was admirable. The doors were none of them swung upon hinges; but run upon small wheels, and were made to slide in by the side of the wall. These wheels or trucks were attached to the upper end of the door, by a small wooden ledge, by which the door was suspended. The door when opened was entirely out of the way. It could be opened a greater or less distance at pleasure. There was no groove at bottom to become filled up with dirt, and obstruct the opening of the door; and there was no occasion of clearing away any snow or accidental obstruction from other matters, which might be accumulated in front, in order to open it. There were also none of the usual troubles of the door being lifted from its hinges, or being slammed and broken by the wind. It was but a small affair, but accomplished much convenience; and is of a piece with every other part of this neat and exact establishment."

THE SHAKER ESTABLISHMENTS

In Berkshire, receive high commendation from the commissioner, as models of order and neatness; a compliment not withheld by any one who visits them. A magnificent circular stone barn, belonging to the society at Hancock is described, three stories high, ninety-six feet in diameter, and capable of stowing three or four hundred tons of hay. All the hay is deposited in the centre, around which is the drive-way, in which several teams may be unloading at the same time. The carts pass into the second story, and the cattle are lodged in the lower one. The society manufacture all their woollen fabrics from their own wool, and carry on the broom making business on an extensive scale.

EXPERIMENTS AND IMPROVEMENTS.

This chapter consists of various experiments in raising and feeding out farm crops, destroying insect enemies, &c. The results are not sufficiently uniform, or the experiments were not conducted with sufficient accuracy, in many cases, to enable us to draw from them profitable conclusions. Indeed many of the results are contradictory or unsatisfactory. They consist of,

1. *Experiments with the potato.*—Several are detailed to ascertain the most economical mode of using seed, and in feeding them to stock. The commissioner remarks that, in his opinion,

> "If a large crop is desired, the seed should be planted in drills, the rows being about two and a half or three feet apart, and the sets placed not less than a foot apart in the rows, that they may be mainly cultivated with the plough. They should not be planted deep; and they should be kept clean. In general few plants are cultivated in a more slovenly manner. Under good cultivation few plants afford more valuable food to an acre. They are, however, I believe, an exhausting, and not an ameliorating crop. They return little to the soil; and the most universal experience is that wheat does by no means so well after potatoes as after Indian corn."

We think that medium sized seed should be preferred; that new seed, grown on a different soil, should be employed every two or three years; that when cultivated in hills a single whole tuber may be used, but when planted in drills, the seed should be cut,—that unfermented manure should be spread broadcast for the crop, and ploughed under; that they should be fed raw to neat cattle, horses, &c. and cooked for swine.

2. *Carrots.*—The product of this crop is stated at from 600 to 1000 bushels an acre. The expenses of the crop are stated from four to nine cents per bushel. The commissioner recommends deep and frequent ploughings, sowing upon ridges two feet broad, the plants thinned to 8 or 12 inches, and that they be harvested with the plough. With the products and expense of culture stated, the carrot is unquestionably a very profitable crop. Their intrinsic value, for every kind of farm stock, may be safely stated at 18 to 25 cents per bushel.

3. *Ruta baga.*—The weight of opinions in Berkshire seems to be decidedly in favor of this root, as a profitable crop, and as an economical food for farm stock; yet there are some who think little of the crop. Every new article of culture has strong obstacles to encounter, before its value can be fairly graduated. It has first prejudices and old habits to combat. There are too many that are always prepared to reject and ridicule whatever they do not themselves originate or introduce. In the second place, the culture of a new crop is often imperfectly managed, and unnecessarily expensive; and many reject a good thing merely because their first efforts are unsuccessful. And there is no class of people who draw more hasty conclusions in these matters, or who are more pertinacious in adhering to old habits, than farmers. The turnip culture had the same prejudices to encounter in Britain that it meets with here; yet still it triumphed there, and it will triumph here—for our soil and climate are as congenial to its growth as the soil and climate of Great Britain and Germany; and it can be made as useful here, in farm economy, as it has been made in Europe. No one *now* doubts its important advantages in British and German husbandry.

We think the commissioner underrates the value of this root, when he says "they are by no means as nutritious as potatoes, especially those kinds of potatoes which are most farinaceous; and they are not comparable to the carrot, or parsnip, or sugar beet for feeding stock." The inference that the common reader would draw from this sentence, would be that the ruta baga is the least *profitable* of all the root crops; and we think precisely the reverse of this to be the case; and for these substantial reasons: 1st. Because they give the greatest average product; this being about four times as great as in the potato. 2d. Because they occupy the ground the shortest time, and are cultivated and harvested, with proper tools and management, with far less expense than other root crops. And 3dly. So far as accurate experiments have been made, their fattening properties are as great, or greater, for neat cattle, as either those of the potato or beet, pound for pound. For proof of the latter fact, we refer to the experiments made under the direction of the Highland society, as noticed in the report upon root culture, in our March No.

There are many other experiments recorded, and results and conclusions stated, which are of but secondary importance; for instance, one gentleman found no benefit from applying lime to his wheat crop; but neither the condition of the lime, nor the quantity are stated; another thinks ploughing in seed wheat better than harrowing it in; another thinks he finds great benefit in harrowing his fields eight or ten days in succession, after the wheat has been sown; another finds that grass is much better after corn than after potatoes, &c. &c. A case is stated of wheat being raised for 20 years in succession in Chelmsford, at the rate of 20 to 30 bushels the acre, with but a single failure; and what is remarkable, the soil, on analysis, was found to contain neither carbonate of lime nor alkaline salts, though the sulphate and phosphate of lime were detected in very small proportions. The commissioner, we think, presumes too much upon this and other facts, in concluding that there is "no difficulty, under proper management, of cultivating wheat in the primitive soils of New-England.

A case is cited, in which the application of lime to wheat, when the dew was on, was supposed to have saved the crop from the ravages of the grain-worm.

AGRICULTURAL SOCIETY.

This society is very justly commended. Says the report,

> "It is remarkable, that in every part of the county, among the farmers themselves, who, as a class of men, are generally distrustful of the advances of such associations, and seem in such matters oftentimes as well skilled as their oxen in the art of 'holding back,' its utility is universally acknowledged, and a strong interest felt in its success. They are every where disposed, in this good matter, to pull together; and it would, as it seems to me, be difficult to find what is technically termed, an 'off ox' in the team."

This was not always the case. The farmers of Berkshire, twenty and twenty-five years ago, were generally as shy, and as mulish, in regard to encouraging the society, as they are every where else, where the benefits of such institutions are not appreciated. It is to the persevering efforts of a few worthy individuals, professional and mercantile as well as agricultural, that the agricultural society of Berkshire has become what it is—an institution of great and palpable usefulness—and that all now cherish and feel proud of it. *All* now agree, that the best effects have resulted from its labors. "It has every where excited and cherished," says Mr. Colman, "a spirit of generous emulation; and men of the highest distinction in the county for education, character, political standing and wealth, give their time and their zeal to its excellent objects."

Like efforts and perseverance, from half a dozen individuals, will produce like benefits, and ultimately the like unanimity in public feeling in its support, in any other county, that it has produced in Berkshire; and there will redound to those who take and keep the lead, the high consolation, of having been instrumental in effecting a great public good, and of having overcome opposition and prejudice, by the exercise of a kind and generous philanthropy.

> "Agriculture, in all its moral aspects," the commissioner very justly and appropriately remarks, "recommends itself to the regard of every good mind. Emulation in this business awakens none of the bad passions, which are so often engendered by rivalry in other departments of life. One man's success in agriculture never injures his neighbor; but always tends to the general benefit. There is in agriculture no monopoly of improvements and advantages; and every effort, discovery, experiment or invention, by which the improvement of the art is advanced, and its productiveness increased, is a direct, substantial and permanent benefit to a town, to the country, and to the world."

> "COMPARATIVE VALUE OF HAY, VEGETABLES AND CORN.
>
> "I wish briefly to draw the attention of farmers to the value of hay, compared with other crops, for the feeding of stock. An acre of hay yields one ton and a half of vegetable food. An acre of carrots or Swedish turnips, will yield from ten to twenty tons; say fifteen tons, which is by no means an exaggerated estimate. It has been ascertained by experiment, that three working horses, fifteen and a half hands high, consumed at the rate of two hundred and twenty-four pounds of hay per week, or five tons one thousand and forty-eight pounds of hay per year, besides twelve gallons of oats each per week, or seventy-eight bushels by the year. An unworked horse consumed at the rate of four and one-quarter tons of hay in the year. The produce, therefore, of nearly six acres of land is necessary to support a working horse by the year; but half an acre of carrots, at six hundred bushels to the acre, with the addition of chopped straw, while the season for their use lasts, will do it as well, if not better. These things do not admit of doubt. They have been subjects of exact trial.
>
> "It is believed that the value of a bushel of Indian corn in straw and meal, will keep a healthy horse in good condition for work a week. An acre of Indian corn which yields sixty bushels, will be ample for the support of a horse through the year. Let the farmer, then, consider whether it be better to maintain his horse upon the produce of half an acre of carrots, which can be cultivated at an expense not greatly exceeding the expense of half an acre of potatoes, or upon half an acre of ruta baga, which can be raised at a less expense than potatoes, or upon the grain produce of an acre of Indian corn, or on the other hand, upon the produce of six acres of his best land in hay and grain; for six acres will hardly do more than to yield nearly six tons of hay and seventy-eight bushels of oats. The same economy might be as successfully introduced into the feeding of our neat cattle and sheep.
>
> "These facts deserve the particular attention of the farmers who are desirous of improving their pecuniary condition. It is obvious how much would be gained by the cultivation which is here suggested; how much more stock would be raised; how much the dairy produce might be increased; and how much the means of enriching the land, and improving the cultivation, would be constantly extending and accumu-

lating. But when we find on a farm of two hundred acres, that the farmer cultivates only two acres of potatoes, one acre of ruta baga, and perhaps a quarter of an acre of carrots, we call this 'getting along,' in the common phrase; but we can hardly dignify it with the name of farming. I am aware that labor of a proper kind is in many cases difficult to be procured, and with our habits, as difficult to be managed.—Farming, likewise, can in few situations be successfully managed, unless the farmer has capital to employ, equal at least to one year's manure and one year's crops. A large portion of our farmers, also, from the nature of their habits and style of living, are so prosperous and independent, that they have no occasion to extend their cultivation beyond what it now is, in order to meet their wants; and to incur all the trouble, vexation and risk of employing more labor, expending more capital, and increasing their cares.

"But it is not fair to produce such instances as any examples of profit or unprofitableness of husbandry, when carried on, as all other branches of business, to be successful, must be carried on, with intelligence, skill, industry, enterprise; and all the capital and all the labor which can be advantageously employed in it. I will not, however, anticipate such general views of the subject, as I propose to take in the retrospect of the whole survey.

"*Apples.*—I should recommend strongly to the farmers of Berkshire, the cultivation of apples. The orchards are comparatively few, and many have been neglected from the best of motives, an unwillingness to favor the facilities of intemperance. But the value of apples for fatting pork and beef, and even for milch cows, so well established by innumerable experiments, and some cases rated as highly as potatoes, recommends them most strongly to increased attention and universal cultivation. The borders of our fields may be lined with them; the road sides may be planted with them; they may be scattered over our pastures, with little or no injury to the crops or the pasturage, if properly arranged."

Brick and Tile Machine.

A machine for manufacturing brick and draining tile is figured and described in the Farmers' Magazine.—The brick machine will mould 24 bricks per minute, 1,440 per hour, and, taking ten hour's work, would give 14,400 per day. A good moulder, with three or four attendants, will make 4,000 bricks per day. The machine, with the same hands, will make 15,000; with this advantage, that the latter will not require half the time to dry, in consequence of the compression which the clay undergoes, and that when burnt they weigh three pounds the heaviest—the mould brick weighing 5 lbs. and the machine bricks 8 lbs. The tile machine will make 10,000 drain tiles a day, with one man and two boys, and 20,000 flat tiles for the drain tiles to lay upon, both 15 inches long. Under the old mode, a man and two boys made but 1,000 drain tiles per day, 12 inches long. The tile made by machine is also much stronger than those made by the old mode, and they are capable of being made from much stronger clay. This machine promises important benefits, wherever tile draining is practised, and will greatly lessen the expense. We should like to see it introduced into this country, with the attendant benefits of under-draining. Draining tile are manufactured in this city, but the price ($15 per thousand,) is such as to deter many from using them. With the machine in question, we are inclined to think they would be afforded at half the present price.

The Pie Plant

Is now coming into extensive use, though three years ago, there was little or no demand for it in our market. There are several varieties of the Rhubarb now employed for culinary purposes, among which are two which have been recently introduced, viz. the *Giant* and the *Tobolsk*, the latter first last spring. The leaf stems of the giant grow to a great size, twelve stocks exhibited by us at the late Horticultural Show weighing twelve and a quarter pounds. We think it makes a pie, if used before it is too old, as fine as any of the varieties. The quality of the Tobolsk we have not yet ascertained.

Early Rising

Is conducive alike to health, to pleasure and to profit—we mean to the farmer. To health because it gives exercise when the atmosphere is most cool, pure and bracing. To pleasure, because nature is then in her most lovely garb, and the birds most full of song. To profit, because the two morning hours effect more in labor, and avert more mischief, than four hours at midday. Early rising, and exercise in the open air, are the best stimuli for our meals, the best anodyne for sound sleep, the best solace for care, and the best evidence of thrift. "*Come boys,*" is the best reveille upon the farm. The farmer who rises late, is generally behind his work; while he who rises early keeps before it.

Comparative value of large and small Turnips.

We have frequently alluded to the fact, that the ruta baga is the only cultivated root, that increases in nutritious properties as it increases in size. Sinclair found, on analysis, that a root of the common turnip, measuring seven inches in diameter, afforded only seventy-two grains and a half of nutritious matter, while the same quantity of a root which measured only four inches afforded eighty grains, or double what the large one gave. The largest root of the Swedish turnip afforded 110 grains, while the middle sized or smaller roots gave but 99. The Swede is stated to have grown to weigh 60 lbs. exclusive of tops and tails, in Van Dieman's Land.

The Army Worm,

A letter from our correspondent at Quincy, Ill. advises us, is making great ravages in that section of the country. We can neither give the history of this new enemy, nor prescribe a mode of destroying them. They are in a measure unknown east of the Allegany mountains. Yet, while penning this notice, our friend Rob. White, jr. of Shrewsbury, N. J. has called upon us, and informs that the army worm appeared in his neighborhood last season, and that this season its ravages have been alarming. When it enters a field it sweeps vegetation almost clean, eating the leaves and even the beards of wheat without disturbing the grain, and divesting the corn wholly of its foliage. Every attempt to check its progress, as trenches, &c. had proved abortive.

The Farmer is Neglected and Forgotten,

In the strife for office, the thirst for popularity, and the eternal contest for charters of all kinds. No reports of any value, no bounties or premiums for new agricultural productions, which might add millions to the wealth of a state, are even thought of for a moment. Because we ask for the least we get nothing. An agricultural school cannot be established, because it might give more power to the dominant party; a pattern farm cannot be established, because it may increase patronage. Where and when is this to end, if we do not take up the matter ourselves, and urge it strongly upon those who call themselves the public servants?—*Correspondent of the American Farmer.*

Miscellaneous Items.

Baldwin's Portable Press—For hay, cotton, &c. is spoken of in the American Farmer, with high commendation, and is likely to save one-third the cost that is now required in the common hydraulic and screw presses. One great advantage of this new press is, that it is portable, and may be placed alongside of the hay-rick, or in the meadow. A common carpenter can make one at a cost of $20 to $25. It will express cider, it is said, without grinding the apples. The address of the patentee, or proprietor, is not given.

An Improved Corn-Sheller, is announced in the same paper, by Wm. Carmichael, of Wye, Queen Ann county, which will shell fifty bushels an hour, by hand or horse power. A two horse power costs $55.

Cerography, is the term applied to a new mode of engraving, for the common letter-press, of maps, music, &c. which promises greatly to reduce expense. The New-York Observer contains a well delineated map of Connecticut, ten by twelve inches, with the names and divisions of towns and counties, and the rivers, roads, &c. as fair as many copper-plate maps, worked off upon the common news press. The editor claims the invention as his own. From what we can judge from the sample, it is likely to prove a very valuable discovery.

Diminution of Neat Cattle in Vermont.—It appears from official returns, that the number of cattle in Vermont underwent a diminution, between 1832 and 1837, of more than 40,000 head; and that in the same period the number of sheep was increased one million. In regard to the exclusive sheep husbandry, Mr. Coleman gives the following relation, as an evidence at least of the inconvenience, which is liable to result from it.—"Two years since, some of the best families in the county of Berkshire were without bread of any kind for a time, from the impossibility of obtaining it. They were persons, for example, who worked for the large wool farmers. They asked for money for their labor; but money was not to be had, because of the clipping of wool, owing to the derangements of business, had not been sold. They asked to receive their pay in grain; but the wool farmers had abandoned all cultivation, for the wool husbandry. They asked for their pay in pork; but the farmers who raised no grain, could raise no pork."

Improvement in Pin-making.—In Britain, pin-making is divided into seven different processes, and the pins, ere they are fit for market, pass through seven sets of hands. Babbage shows, that one-half the expense of manufacturing is saved by this division of labor. Messrs. Stourm, Jillson & Co. of Poughkeepsie, by a new invented machine, have reduced the manufacture almost to a single process. "The wire of which the pins are made," says the Poughkeepsie Journal, "is taken into the machines, and the process of making the pins, with solid heads, all from the wire, is completed by the machines, leaving nothing remaining to be done, except the washing and placing them upon papers. One man will attend two machines, and each machine will turn out 100,000 pins in eleven hours. The proprietors have now two tons on hand, of a quality far superior to all others."

Extirpation of Garlick.—Thomas E. Bond, in the American Farmer, says he has wholly destroyed the wild onion, in fields which have been over-run with it, by first cultivating them in corn, and, after the corn was gathered, ploughing the field again, and leaving it exposed the succeeding winter in the state the plough had left it. The same gentleman says, that *St. Johnswort,* another troublesome weed, may be killed by a single ploughing in the early part of June, when it is in blossom, provided the ploughman, by means of a heavy chain attached to the plough, in the usual way, covers the plant effectually. If completely covered it will die.

A sale of Durham Cattle, belonging to Messrs. Gratz & Cooper, took place near Lexington, Ky. on the 14th June. Three males sold for $900, $280 and $760; and seven females for $601, $630, $631, $700, $861, $446 and $1,050—average $685.90—as stated in the *Franklin Farmer.*

Bloody Murrain.—It is stated in the *Franklin Farmer,* that this complaint has been cured, in its last stage, by simply giving the animal two doses of sugar of a pound each, mixed with water.

Salt your Fruit Trees.—A writer in one of our exchanges, mentions a decaying plum tree that stood in the midst of an asparagus bed, which, on dressing the bed copiously with pickle, began to revive and became healthy and fruitful. He accordingly recommends the free application of salt to such trees—presuming it will produce a similar effect.

Whitewash for all Buildings, inside or out.—Take clean lumps of well burnt lime, slacked. Add one-fourth pound whiting or burnt alum pulverized, one pound of loaf sugar, three quarts of rice flour made in a thin well boiled paste, and one pound of cleanest glue, dissolved as cabinet makers do. This may be put on cold within doors, but hot outside. This will be as brilliant as Plaster of Paris, and retain its brilliancy for many years. The east end of the president's house in Washington, is washed with it.—*Cincinnati Chron.*

Whitewash is one of the finest things in the world to promote health and cleanliness. It also covers up a multitude of dirt, as a cloak conceals the rents in an old garment. Some farm houses look black and unsightly, while the crevices in the wood admit the rain. Perhaps they are not worth painting—but a coat of whitewash, which costs but a few hours of labor, with water and lime, does the work. They look fresh and clean, and during a year the wash is soiled but little. We commend a coat of this to every man who has an unpainted house, both on the score of beauty and taste, as well as for cleanliness and the preservation of his building.—*Northampton Cour.*

Stopping a leak.—The best thing for stopping a leak in a cask is whiting beaten up with common yellow soap. If this mixture be well rubbed into the leak, it will be found to stop it after every thing else has failed.—*Farm. Cabinet.*

Short-Horned Cattle.—Never think of buying short-horned or Durham cattle, until you are prepared to keep them well. They need an abundance of fresh pasture, and therefore to be frequently changed from one pasture to another, in succession, and plenty of food and good shelters in the winter. Thus provided for, they are valuable stock. But neglected in these respects, they are little better than native cattle.—*Franklin Far.*

Productive Cows.—A short-horn, belonging to Mr. Wolbert, Philadelphia, gives daily 27 quarts of rich milk, upon ordinary feed; from which 14¾ lbs. of butter were made in a week. A cow belonging to Mr. Gowan, of Germantown, gave an average of more than 28 quarts of milk per day, for a week.

THE BUDGET.

Culture of the Strawberry.—R. Mansfield will find an answer to his inquiries in the Cultivator for August, 1838. August is a good season to transplant the strawberry.

Disease of Dutton Corn.—George H. Patrick, of Kanawha C. H. Va. states in a letter to us, that his Dutton corn, when about two feet high, showed symptoms of disease and death; that on taking up some plants he found, on applying the magnifying glass, a small green bug upon the roots, some of which were literally covered with the insect; that his other corn did not seem to be affected; that the seed of the Dutton corn came from us; and he inquires whether it did not become impregnated with the ova of the insect during its soft milky state, the same as the pea—and whether the contagion, or insect, is not likely to spread to his other corn. We are unable to explain the matter. Nothing of the kind has ever appeared in our crop, or has before ever come to our knowledge. The ova could not have been deposited in the seed, but why the animalcula attacks only one variety we are unable to guess.

Mr. Patrick adds—"The root culture has just commenced with us. Many are putting in small lots of mangold wurzel, parsnips, &c. and will put in, in due time, ruta baga. The Cultivator and the formation of our agricultural society, with premiums offered to the amount of five hundred dollars, has given us such a spirit of improvement in agriculture, that I am much in hope, with your assistance, we shall not return again to the old mode of cultivating the soil." We beg Mr. P. not to forget his good intentions.

Manual Labor School.—We are requested by a correspondent, to notice a select classical manual labor school, which has been established at Montvue, post-office Middletown, Frederick co. Va. by the Rev. John Lodor. The manual labor may be voluntary, and is intended as a healthful exercise, and as a means of defraying the expense of tuition.

The Rohan Potato.—In reply to the inquiry of Mr. Harris, of Orange C. H. Va. we state, that this potato should be *cultivated* like other potatoes; that the *seed,* that is balls, should be gathered when they have matured, be dried, preserved from frost, and sown in the spring, in a bed of fine mould, and taken care of like other plants.

Price of Animals, &c.—A correspondent at Columbus, Miss. writes as follows:—"I perceive you have commenced inserting advertisements. I wish you would impress upon those who offer articles of any kind for sale, the propriety of stating the price. I am aware that many do not like to make their price public; but those abroad could often make up their mind about what is offered by knowing the price; that is, many would know if their means would allow them to purchase." The drawings, &c. of sheep teeth, sent us by a correspondent, were inserted in our second volume, p. 188.

Acknowledgments.

"The District School as it was," from the author.—This is an excellent picture, delineating, in vivid colors, the defects of the old system of instruction.

An assortment of thirty kinds of Cape Bulbs, in fine order, from Jonathan Edwards, Esq. of Troy, collected in South Africa, by the Rev. Geo. Champion.

From Dr. A. Walcott, of Clinton, Ct. through W. C. Wilcox, a box of "*Patent Restorative*," for the purpose of restoring to the earth its original fertility. This article, Mr. Wilcox informs us, "has lately been discovered and manufactured by Dr. W. after a series of observations and trials. For one acre of grain or grass, two bushels of the preparation would be sufficient; Indian corn would require three bushels—to be sprinkled on the surface after ploughing and harrowing."

Chenango Potatoes from J. G. Buswell. These potatoes are old acquaintances. We received a barrel from a friend in Lancaster county, Pa. in 1827, under the name of Mercers, cultivated and liked them. We sent a barrel to Boston, in 1828, containing samples of Mercers, Pinkeyes, and Kidneys or Foxites, and our late friend Fessenden, then editor of the N. E. Farmer, pronounced the Mercer to be best. Yet as they then had not *got their name up*, no one would buy them, and we discontinued their culture—for those who raise for market must suit the taste of their customers, and not their own. We are glad to recognize our old acquaintance, and feel pleased that they have come into deserved favor.

A highly finished scythe snath, the donor's name mislaid and not remembered.

Prof. Jackson's Geological Reports, from Mr. Webb, of Boston.

"*Agricultural*" and "*Horticultural*" Razors, from A. Walsh, Esq. of Lansingburgh.

☞ Agreeable to our proposition, we shall issue our next No. on the 15th Aug. and shall insert in it the essays and diagrams on farm dwelling-houses.

CORRESPONDENCE.

The Sugar Beet—Queries.

Guilford, near White-Post P. O.
Clark Co. Va. July 3, 1839.

Judge Buel—Sir—I have recently become a subscriber to, and a constant reader of your valuable and interesting paper, the Cultivator, and as I desire information respecting the culture of the sugar beet, I am sure it will give you pleasure, thus to promote improvement, by diffusing useful knowledge.

A member of my family being about to commence farming, on what we consider here as a small scale, a farm of 200 acres, which, in ordinary seasons, will produce five or six barrels of corn, or twelve or fifteen bushels of wheat to the acre, wishes also to combine with it, the culture of the sugar beet, if, after inquiry, it shall be advisable to do so. It is limestone land, of a light soil, and the cleared parts much exhausted by excessive cultivation, until the last thirty years, when it changed hands, and since then has been gradually improved to the state above mentioned. The part in woods contains black oak, white oak, hickory, walnut and ash. From this description of our lands, you will, perhaps, be able to decide whether they are adapted to the sugar beet.

In a letter, published in the National Intelligencer, a few months ago, from Mr. Ellsworth, the commissioner of patents, he stated that an acre of good land would produce twenty tons of the sugar beet, which would make 3,600 lbs. sugar, worth seven cts. per lb. Now if our lands would yield the half or a fourth of that quantity, it would be infinitely better for us to go to making sugar at once, instead of raising corn and wheat at a heavy expense, while the seasons are so precarious, and the prices so fluctuating.

You stated, in a report on "root culture," in the March number of the Cultivator, for 1839, that "from the high state of perfection and of profit, which the business has arrived at in France and Germany, that the culture of this beet will soon be extensively gone into in this country, for the purpose of making sugar." In this opinion, sir, I fully concur, but how to obtain the information which is requisite to enable us to begin a business so entirely new here, is the difficulty I desire to remove. Will you, then, or some of your correspondents, do me the favor to say,

1st. What is the best time and mode of preparing land for the sugar beet?

2nd. Whether it is best to sow it broad-cast, or in drills, when land is cheap and labor dear, and what would be considered a reasonable crop, from land rich enough only to produce six or seven barrels of corn per acre?

3d. How many acres in beets can one hand cultivate, supposing him to have little else to do?

4th. What is the best way of preserving them in winter, where there are no root houses for the purpose?

5th. Do you know of any individual, or company, in New York or Pennsylvania, or even nearer to me, that is engaged in the manufacture of sugar from the beet?

6th. Can you inform we what such a manufactory would cost, and whether it is worked by water, steam or horse power?

7th. What is the practice in France or Germany, amongst those who cultivate the sugar beet, in regard to its manufacture? Does the farmer make his own sugar, or are there public establishments, like our mills, and the manufacture of the beet a distinct occupation from the raising of it? Since the plan of kiln drying the beet has been adopted, it would, I presume, bear transportation to market as well as other products.

8th. Is there any French or German work, (translated into English,) on the subject, in the book-stores of New-York or Philadelphia, that you can recommend?

Any information, not embraced in the above interrogatories, which may be deemed pertinent to the occasion, will be, I assure you, sir, most thankfully received, by your very ob't. and humble serv't,

JAMES M. HITE.

ANSWERS.

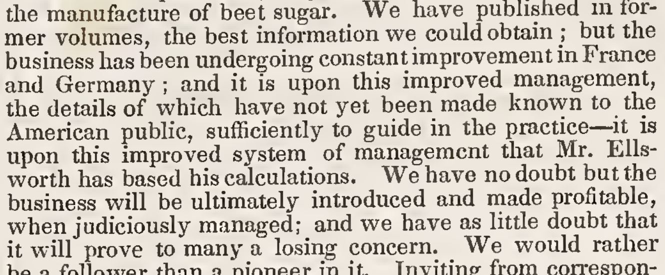
We are not practically acquainted with the beet culture or the manufacture of beet sugar. We have published in former volumes, the best information we could obtain; but the business has been undergoing constant improvement in France and Germany; and it is upon this improved management, the details of which have not yet been made known to the American public, sufficiently to guide in the practice—it is upon this improved system of management that Mr. Ellsworth has based his calculations. We have no doubt but the business will be ultimately introduced and made profitable, when judiciously managed; and we have as little doubt that it will prove to many a losing concern. We would rather be a follower than a pioneer in it. Inviting from correspondents a more general answer to Mr. Hite's queries, we will content ourselves for the present, with responding briefly to some of his inquiries. And,

1. The best time and mode for preparing land for the beet, is to apply manure to the previous crop, and to deposite the seed immediately after the preparation is completed, upon the fresh turned soil.
2. The seed should be sown in drills—to save labor. A reasonable crop would be from five to six hundred bushels.
3. A man can tend half as much ground in beets as he can in corn.
4. The beets *have been* preserved in the manufactory in France. They *may* be preserved in pits. If dried, they may be preserved wherever they can be kept dry.
5. We can give no particular reference.

To the other three inquiries we can give no satisfactory answers; but the coming six months, we hope, will afford us the means of being more explicit in the matter. We will not withhold from Mr. Hite, our impression, that the climate of Virginia is not well adapted to the culture of the sugar beet—that it is too far south—the root in the south of France being far less rich in saccharine matter than that grown in the northern departments. We do not pretend to determine the beet zone; but we are inclined to think, that upon our Atlantic border, it is north of 42°.—*Cond. Cult.*

Plan of an Improved Gate.

[Fig. No. 21.]



Plattekill, 6 *mo.* 24, 1839.

Respected Friend J. Buel—As I was perusing the last number of the Cultivator, I observed the description of the revolving gate. I think that I shall be doing good rather than hurt to send thee a description of one of those that I erected last summer; they are new with us and may be with you. I find them to surpass all others that I have ever seen; and I doubt not but what thy correspondent will acknowledge with me after he has seen them fully tried. I think it is a duty that we owe to one another to impart instruction, and at the same time be willing to receive it; and I hope that none will forget that we may live and learn all our days. As I have taken the Cultivator for two years past in company with another gentleman, I may say that I feel highly thankful for the knowledge and many benefits that I have received from the pages of that most noble paper.

It is made as follows: set three posts, 6 feet 6 inches high, of an equal distance apart, one extending along the fence in the direction that would best suit for the gate to slide. I send thee a drawing of this gate, to enable thee to understand it the better: *a a a* posts, *b* crosspiece nailed fast to the back and middle posts for the gate to roll upon, (*c* crosspiece); when the gate is slid open, it will rest upon the point of the crosspiece *b*; then the crosspiece *c* is at full liberty to be taken out: *d d* cleats which are nailed thoroughly on each end of the slats, and extend to a sufficient height to straddle the crosspieces, in which is inserted the rollers *e e*, which are made of cast iron with us, which are preferable to wood; *f* cleat which is nailed on the middle post after the gate is hung, with sufficient pieces of wood, or what some carpenters style furring inserted, to admit the gate to slide with freedom; *g g g g g* slats, the ends of which are admitted to extend an inch through the front cleats, for the purpose of striking into some mortice which is made in the front post: or else by nailing on cleats. I made them by nailing on strips of inch boards; *h* hook to hook it fast if needful; I never have found it necessary. The above represents a gate partly open.

I hope that no person will raise any objection to these gates till he has tried them; then I think he will have none to give.

Any farmer can make one with the aid of an axe, saw, hammer and nails, in six hours' time. They are very simple, and cost not more than one-quarter that of ordinary gates, and many advantages that I might mention. Thine most respectfully,

STEPHEN TABER.

Early Rising.

Hon. J. Buel—Dear Sir—As your paper has a very extensive circulation, I desire to present before your numerous readers, a few arguments in favor of early rising. The couplet of the sage, so long familiar to the community generally, contains much more truth than men *practically* believe:

> "Early to bed and early to rise,
> Will make one healthy, wealthy, and wise."

Many who have pursued this course, have enjoyed much better health and other comforts than many others who have pursued an entirely different course. The reasons for this may be very obvious to those who have reflected upon it with only a little attention, especially if their practice has been in accordance.

In the first place, our Creator has hung out the sun from the heavens, for the benefit of his creatures. If we lie in bed after his precious rays shine around our habitation, we deprive ourselves of much comfort, which we might have enjoyed in the sublime and beautiful sight of beholding the trees and distant hills, first enlightened by his golden beams. Besides in the spring and summer seasons, especially in country places, where *farmers* generally reside, those who sleep until after the sun has arisen, lose most of the pleasure and benefit which they might have by listening to the inimitable songs of the feathered tribes.

Again—the *farmer* and *gardener* need to be early abroad to prevent the intrusion of many enemies upon their crops, or to banish them soon if they appear. Some have never seen, for instance, the cut worm, in the very act of his depredations; but after the sun has risen, they have often had painful demonstration, while standing by their fallen plants, that such an enemy is in existence. Had they been in their garden or field as soon as the dawning day, carefully watching by the side of their plants, it is at least possible they might have been convinced *how* the work was accomplished.

Again—many complain that their vines are destroyed by the little striped bugs, and before they have opportunity to destroy them, they take wing and fly away, ready to return again at their own convenient time. I would say to such, be at your post a sufficient time before the sun makes his appearance, and you may secure many of them from futher depredations.

Once more—many plants may be essentially benefitted by stirring the dirt around them every morning, while the dew is on. Their growth may be promoted, and often the effects of drought prevented, and many other benefits obtained. Some plants, it is true, may receive more benefit to be hoed when the dew has disappeared, but enough may be benefitted to occupy an early hour. Will you make the experiment? Will you in future rise early?

The Season, Crops and Insects in South-Carolina.

Oakley Farm, Chester District,
S. C. June, 27, 1839.

Judge Buel—We are suffering here severely from drought. The whole spring has been dry—our gardens are burnt up, without having yet given us anything; from 6 beds of peas planted in succession, I have not had half a dozen messes; our corn is in a most deplorable state, now tasseling-out—wilted and must soon perish if we do not get rain in a few days. We have had but one rain to wet the earth below the furrow of a shovel plough since the 8th of May,—and very little all April. We have, notwithstanding, made good crops of wheat for us, where it is not generally sown as a market crop,—and commonly put in very carelessly for family use.

Though we are not yet afflicted with the "grain worm," nor much injured by the Hessian fly; a pest has appeared among us within the last two years, which from their prodigious numbers and destructiveness threaten to be even a more serious evil to us. They are called chinchbugs in Va. though they have no resemblance to our domestic pests but their disgusting smell. They are nearly the shape and size of the small black flour weevil; can fly, but take to their wings reluctantly; have no mandibles, but a proboscis with which they penetrate the stalks of plants near the joints, and suck them to death. They have destroyed my oat crop totally: I shall not make the seed sown; my white May wheat (harvested 28th of May) came to maturity too early for them, and was but slightly injured; but my white bearded wheat (harvested 12th of June) was seriously injured by them,—many ears not having a single grain filled in them. Bad as this is, it is nothing to what followed; for as soon as the small grain was cut, they took to our corn fields in such myriads as is inconceivable to any but those who have witnessed them; I have seen some of my corn so perfectly black with them for two feet up, no particle of green was to be seen but 5 or 6 inches of the tips of the leaves; and they hung to the under parts of them in knots like little swarms of bees. It takes them only one or two days to destroy the corn; from such an attack I saw no remedy but burning them up, corn and all; and by promptly doing so in that part of the field into which they first migrated in such immense numbers, hope I have saved the rest of it from total ruin—though patches of corn in some of my other fields have been totally killed. This is indeed a long letter about a little thing, and just to ask you, sir, if you know anything about them, and what would be the best remedy against them? and trusting you will excuse the trouble of this, I remain, respectfully,

W. S. GIBBES.

New Husbandry, &c.

Mocksville, N. C. June 18, 1839.

JUDGE BUEL—Dear Sir—In recommending the new system of husbandry to our farmers, I meet with two objections to it; one is, that we have too much cleared land to manage our farming in that way; and the other is, that when a man is in debt, and is obliged to have a certain amount of money from his crops every year, he can't enter upon that plan, as his crops would be lessened for some years, and therefore he could not meet his engagements. I think the first objection is very correctly answered in the March number of the Cultivator for this year, in your reply to the inquiry of John Ogilvie, of Virginia, as to Agricola's farm; and I would like to know your opinion, as to how long it would be before a man's crops would yield the same return, under the new plan, that it now does under the old, the same amount of labor and capital being employed in both cases, taking it for granted that his crops would be less at the start in consequence of his tending so much less land, a small part only of which he could manure the first year.* I can add my testimony in favor of Green's straw cutter. I have procured one, and it performs first rate; every one is pleased with it who has seen it perform.

I soaked a part of my seed corn this year upon your plan; it came up well, and grows more rapidly than that which was not soaked, and was scarcely touched by birds or squirrels, while that which was not soaked and planted along side of it, was taken up badly by them. I don't think soaking seed corn is so necessary in our climate, as it is in a more northern one.

Will Irish potatoes intermix, by planting different sorts along side of each other?† The above is at your disposal. Enclosed are $11, for as many copies of the Cultivator for this year. Accept my acknowledgements for the box of potatoes and corn, which came safe to hand; the Rohans were perfectly sound, the others were a little damaged. Respectfully, C. HARBIN.

Queries and Answers Subjoined.

Michigan, June 14, 1839.

Mr. BUEL—Dear Sir—Being somewhat anxious to obtain something like answers to the following questions, or queries, and being sure that I cannot resort to a source from which I shall be more likely to gain the information I so greatly desire, and believing them to be within the design of your invaluable paper, I am encouraged to ask the favor of your honor.

In rearing a nursery of fruit trees, is it best to sow the seeds in beds, and transplant the trees, or should they be sown where they are to remain until fit for the orchard? *Answer—Sow in beds and transplant.*

What distance from each other should they stand in the nursery? *Ans.—One foot in the rows, and the rows three feet apart.*

Can all or any of the various kinds of fruit trees, be raised from the scions by cutting, as for grafting, dipping the ends cut in melted pitch, &c.? *Ans.—No fruit trees, that we now recollect, will grow well from cuttings, but several of the fruit shrubs, as the quince, currant, gooseberry, &c. will grow from cuttings. The roots of most fruit trees, as the plum, apple, pear, &c. if made into cuttings, will grow, if properly buried.*

Will the trees from the stone of the peach, plum, cherry, apricot, &c. produce fruit of the same quality as did the trees on which they grew? *Ans.—Very seldom. The seeds cannot be depended on to produce like the parent plants.*

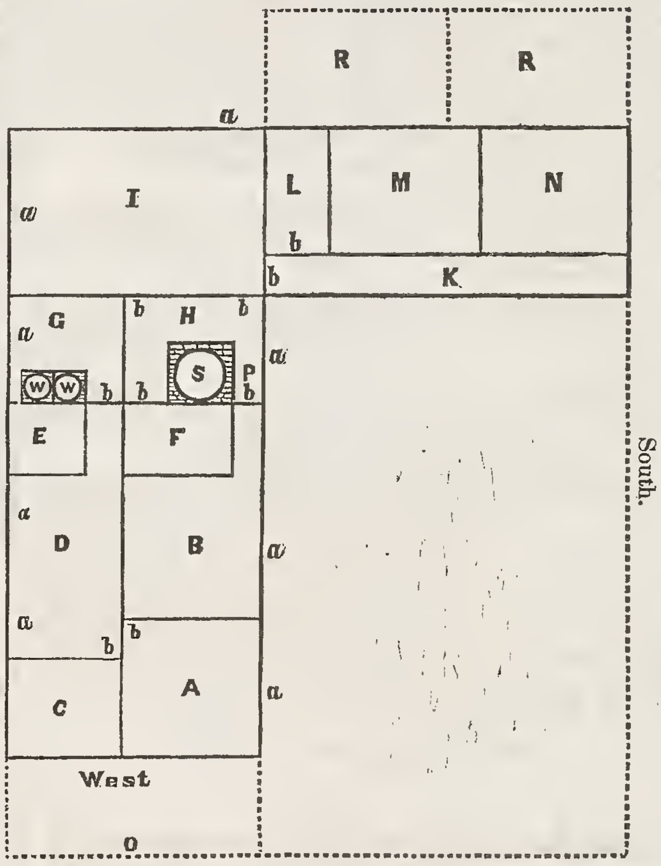
Which is the best time, (fall or spring,) to remove trees, say from the state of N. Y. to Michigan or Wisconsin, and how early in the fall, or how late in the spring, may they be taken up for that purpose? *Ans.—We have sent them at both seasons, in autumn generally by the way of New-Orleans, and in spring by way of the Ohio canal or Chicago. They may be removed, in autumn, so as to reach Cleaveland or Detroit before the 1st November, and in the spring as soon as the canals are navigable, say the 12th April.*

What are the names of the choicest apples, pears, &c. known in your section of the country, and where can either or both scions and trees fit for orchards of such choice fruit be had? *Ans.—A list of good pears will be found in the May No. of the Cultivator. A list of apples and other fruit will be forwarded to our correspondent, when we know his address. Address J. Buel & Co. nurserymen, Albany.*

An answer or an opinion relative to the above, or to any part thereof, will be very thankfully received by at least one SUBSCRIBER.

Ground Plan of an Out-Building.

[Fig. No. 21.]



In this plan, the dotted line O, represents the west fence, or line of the road, which runs north and south, or nearly so; the house west of the kettles is of brick, and two stories high; that part east of the kettles, of wood, and is only one story; the wing that runs south, is covered with a shed, the use of which may be described in some future communication, as what I have here sketched is all intended to represent cellars and piggery. The ground rises gently from the road to the centre of the building spot, and then falls rapidly, so as to give a chance for the hog-yards, R, R. In the figure, A, is a cellar 14 by 15, for garden sauce and ruta bagas. B, potato cellar, same size, with communications to empty potatoes by window *a*, from cart body to cellar, with access through door *b* to swill kettle S. C, Ice cellar. D, Meat cellar, &c. E, Brick cupboard, flat stone for bottom and top. F, Ashery, communicating with kitchen fire-place above, flat stone covering top and bottom of this also. G, Wash cellar. H, Swill room. I, Wood room, communicating directly with wood room above. K, Alley, 4 feet wide, where we feed hogs and pass out door at south end of shed. L, Meal room, 8 by 14, where hog meal is kept, and communicates by a tube or tunnel with the meal room above, so as to carry hog meal from door yard in front of the shed, into the meal room in the shed, and pass it through the floor into the hog meal room. M, N, Hog-pens, 14 by 16; here we have Heaton's plan for feeding hogs, with a slight variation. O, Fence. P, Lead pipe, furnishing cellar and kitchen with water, and thus passing out at east of cellar, through window *a*, from which we water our hog-yards. R, R, Hog-yards, with doors hung at top, so that hogs open them and their own heft shuts them; heighth of doors 2½ feet. S, Swill kettle. W, W, Wash kettles. *a*, *a*, &c. Cellar windows, with cast iron sash. *b*, *b*, &c. Doors.

Perhaps it will be proper here to state, that we adopted a new plan in building our cellar wall, which was this:—We in the first place commenced a very thick wall of split granite, and after carrying it to the heighth of four feet, or half the depth of the cellar, we made an offset or jog of five inches, which carried the face of the wall five inches further back, on the upper than on the lower section or half of the wall; that is, five inches farther towards the bank. On the offset, (for so I must call it, not being master of our language sufficiently to apply a better name,) we commenced a course of brick, leaving a space of one inch clear between the lining and wall, and carrying it quite to the top of the underpinning, where it was thoroughly connected and bound to the underpinning, which is of hewn granite; and the top of the lining, together with the underpinning, presented a surface of 17 inches wide, which was sufficient to receive the wall of the house, which was 12 inches, leaving 5 inches on which the floor timbers rest. Thus we have placed an effectual barrier against that enemy of cellars *Jack Frost*, and this, too, with but single glazing, giving the light of the sun free access to our cellars in all seasons, and making the swill room so warm that swill will not freeze in the coldest weather; and even our hog-pens are so warm, (being walled on the west side of the pig or hog-pen alley, and at the north likewise, and the east and south well boarded, accompanied with self-shutting doors, for the ingress or egress of the swine,) that it requires severe cold weather to freeze the swill even in the troughs. The two story or brick part of the house extends from the west end to the line separating the three kettles from the brick cupboard and ashery, or smoke-house, where the east end of the brick part commences, at the bottom of the cellar, carrying with it the flues for the kettles, together with the smoke of four fire places in the lower story and two in the upper, and this all in two chimneys, so that these with two small ones at the west end of the house, accommodates our whole farming establishment as to chimneys. W. C.

Fairlie, Orange co. Vt. June 22, 1839.

On the Application of Manures.

Fredericksburgh, Va. June 18th, 1839.

J. BUEL—Dear Sir—In your paper for the present month, I have read the following intimation; "*a subscriber wishes Mr. Garnet's opinion of the best method of applying manures to land;*" and presuming that I am the person meant, I avail myself of the earliest opportunity to evince my willingness to gratify him. But as no man's mere opinion on such subjects, is worth any thing without the facts and reasons upon which it is founded, I shall take it for granted, that he desires to hear both, and will therefore state them together.

Whether your subscriber means by the term "*manures,*" all things commonly so called, or only putrescent substances, I have had but one opinion for a long time, in regard to their application, and this has been confirmed by all my subsequent experience, each year adding something to the great mass of consantaneous facts. When my attention was first turned to this subject, some thirty-five or forty years ago, I had adopted, but without examination, the notion then most common amongst us, that it was best to let all putrescent manures be well rotted first, and next, to bury them deep, either by the plough, spade, or hoe. This notion, like the common law, was so old, that "the memory of man extended not to the contrary;" but happily for us all, the revolution had broken the entail of opinions as well as of landed estates, and left us at liberty to think and act for ourselves. The natural consequence of this increased freedom was, the introduction of many new practices in the arts, as well as in government; and agriculture came in for some small share of these benefits. Among them, was the application of putrescent manures to the surface, and in a much less fermented state than had ever been tried before. But so dreadfully afraid were the first experimenters of the formidable laugh of that once numerous family, "The Goodenoughs," that they made their trials, as it were, by stealth; and consequently, the results remained, for a long time, unknown, except to a few. I happened to be among the number, and could not long resist the evidence of my senses, although I must confess, that at first, it seemed to me a sort of sacrilege, even to doubt, and still more to act, in direct opposition to an opinion which, for aught I know, had descended from Triptolemus himself. By degrees, however, my courage waxed stronger and stronger every year, until I felt myself brave enough to commence the following experiment, which several old farmers in whose veracity I perfectly confided, had assured me they had often tried, and always with the same result, as that which I am about to report in my own case.

I began penning my cattle late in the spring, and continued it until frost, in pens of the same size, moved at regular intervals of time, and containing the same number of cattle during the whole period. These pens were alternately ploughed, and left unploughed, until the following spring, when all were planted in corn, immediately followed by wheat. The superiority of both crops on all the pens which had remained unploughed for so many months, after the cattle had manured them, was just as distinctly marked as if the dividing fences had continued standing: it was too plain to admit even of the slightest doubt. A near neighbor, a young farmer, had made the same experiment, on a somewhat different soil, the year before, but with results precisely the same. Similar trials I myself have made and seen made by others with dry straw, alternately ploughed in as soon as spread, and left on the surface until the next spring. In every case the last method proved best, as far as the following crop would prove it. The same experiment has been made by myself and others of my acquaintance, with manure from the horse-stables and winter-farm pens, consisting of much unrotted corn offal; and without a solitary exception, either seen by me, or heard of, the surface application, after the corn was planted, produced most manifestly, the best crop. Upon these numerous, concurrent, and undeniable facts my opinion has been founded, that *it is best to apply manures on the surface of land;* and "I guess," (as brother Jonathan would say,) that it is not likely to change, unless indeed, I should hear a still greater number, equally well authenticated, on the opposite side; although I must say, that up to the present time, I have not heard a solitary one. True it is, that I have read many ingenious, fine spun arguments in opposition to the opinion which I hold in common with numerous other agriculturists, but no proofs whatever have accompanied them, and therefore I must remain an infidel, until they are sustained and corroborated, by such facts, as should always be deemed indispensable to establish any practice whatever, in any of the various branches of husbandry. To collect these facts is a slow, and most tedious process, not very flattering to that pride of opinion which delights in speculative theories of our own elucidation, and sickens at the mere thought of the labor necessary to make, to watch, and to record accurate experiments in agriculture. In no other way, I think, can we account for those differences of opinion as to matters of practice, which are often found among our brethren, where all the facts are on one side. But to refuse to believe in that which we cannot explain, unless in some way that tickles our own vanity, gave rise to the sect of sceptic philosophers, and it is to be feared, will keep up the breed as long as the world stands. Let me not be here misunderstood. Far be it from me to object to theory and speculation, provided the sole object in concocting and maintaining them, be to arrive at truth. As this should be the aim of all, I am in favor of the utmost latitude of discussion in the honest pursuit of it. But I do, and will forever protest against that practice which is far too common amongst us, of regarding plausible and apparently scientific conjectures, so much more than the actual results of experiments fairly and accurately made, as not unfrequently to indulge our fancies with the former, even in direct opposition to the latter. Take, for example, the two conflicting creeds as to the best mode of applying manures, and test them by the uniformly concurring results of the several experiments which I have stated. All these results undeniably prove, that the surface application was best; although the kinds of manure differed considerably. And what have we in opposition, any facts whatever? Not one; and only the conjecture, that the evaporation from surface spread manure must carry off the greater and best portion of the food of plants therein contained. But that such evaporation cannot thus act, seems to me to be unquestionably proved by every fact I have mentioned: for, *if it did*, then the land of summer cow-pens ploughed up as soon as removed, would, in every case, have produced better crops, than that of the *unploughed*, instead of doing it in none. Similar results too must have followed in the other cases I have stated, although I have never seen nor heard of their doing it in any. The effects however, which *really have taken place*, (facts though they undeniably are,) happen to contradict, as plainly as we see the nose on a man's face, certain preconceived fictions, or ingenious theories, if you please to call them so—quoad manures—in the propagation of which much paper and ink has already been consumed, much head-work is still employed; and what is to be done? Shall all this labor, all the ponderous volumes elaborated by it, all the cogitations in support of those theories, which are now taking the rounds in our agricultural papers—shall all be discarded as things serving only to show how much fonder men are of their own speculations, than of facts the occurrence of which brings them no credit for remarkable talents? Or, shall we still cling to these theories, maugre the facts, merely because we have already shed so much ink, and spent so much time in laborious efforts to sustain them? I can answer only for myself by saying, that I will ever abide by facts in preference even to my own opinion, whenever they conflict with each other. But in regard to the subject now under consideration, I believe there is a perfect accordance between them. Your subscriber however, may possibly think that I have "jumped too speedily to my conclusions;" I will therefore, respectfully offer to him such explanation of the operation of surface spread manures, as has been satisfactory, at least to myself. Should it prove so to him, I shall have gained my object in complying with his request.

---

* We mean explicitly to state, that if a man has one hundred acres of ordinary land, which he wants to plant in corn, and but three hundred loads of manure to put upon it, he had better bestow his manure and his labor upon twelve, than upon the one hundred acres. His labor will be lessened two-thirds at least, his products will be greater, and the eighty-eight acres, which is left to rest, instead of being further run down, will be in some measure renovated by the herbage which grows and decays upon them. The herbage of an acre will *keep alive* ten sheep, will *keep in good condition* six, and will *fatten* four. Would the owner, who was in haste to convert his sheep into mutton, and to realize the avails in cash, find it most profitable to feed his acre with ten, or six, or four sheep? So with corn, it will live without manure, upon poor lands; it will grow without manure, upon lands which are in tolerable order; but it will only give a remunerating, or a very profitable crop, when highly fed, or manured. Bordley rated the average product of corn, upon the eastern shore of Maryland, at 15 bushels an acre. We say, that the average product here may be raised to 80 bushels per acre. Charge the crop with us $25 for the 25 loads of manure; estimate the grain at 75 cents per bushel, and the expense of culture at $15. The one hundred acre corn farmer then expends $1,500 in labor, and gets $1,145 for his crop—loss $355. The twelve acre corn farmer expends $180 for labor, $273 for manure—total $555—and gets for his corn—12 multiplied by 80 is 960—he gets for his crop $720—nett profit $165—thus showing a difference in the nett profits of the twelve acres, highly manured, of $520, in a single season, upon the data of calculation we have assumed, over the one hundred acres planted without manure. Mr. Harbin will see from this estimate, although it may be termed an extravagant one, that a maize crop would yield, immediately, a far better return "under the new plan, than it does under the old."—*Cond. Cult.*

† They will not.

My belief, founded on the facts already stated, *is*, that all the fertilizing substances of manures are soluble in water, and will remain uninjured themselves, and useless to plants until the solution begins, whether they be deposited *on* or *under* the earth's surface. I also believe, that this solution is caused by every fall of rain, and is immediately absorbed by the subjacent soil, which absorption results from two causes; first, the principle of gravity, and secondly, the stronger attraction of the earth than of the atmosphere, for every substance in solution which constitutes the food of plants. Moreover, that the earth never parts with this food, when thus absorbed, to any thing but the plants themselves; for it is *their* peculiar aliment, and not that of the atmosphere, whose existence, for ought we know to the contrary, is entirely independent of it, although its agency seems essential to the health and vigour of all plants. If this were not the fact; if, (for example,) the earth did give the best and greatest portion of this food to the atmosphere; or, if it escaped from surface spread manure, before gravity and attraction could impart it to the earth, then the evaporation which is supposed to be the medium of conveyance, and which is known to be constantly going on from the soil, would, in process of time, certainly render it barren, even without any cultivation whatever. Yet neither total nor partial barrenness is ever known to be produced by any other cause, than incessant culture without manure. That evaporation does take off something from manure while in a moist state, is proved by the offensive smell which constantly exhales from it until it is entirely dry. This smell is excited by a gas which is said by some, to contain the most valuable portion of the food of plants. But admit the fact, where is the proof this portion being lost? I say there is none. On the contrary, we have what I think a conclusive reason for believing, that this food is immediately given by the atmosphere to the tops of plants, as more suitable to them than to their roots. My reason for this belief is, the result of the following experiment which I have known to be repeated several times. All the bark was taken off from around the body of certain young trees, in a ring about three inches wide, for the purpose, in the first case which I saw, of ascertaining whether this process would not kill the tree. But to the surprise of us all, not more than a year or two elapsed, before that part of the body above the ring became obviously larger than the part below, and this difference in size increased every year afterwards, as I had frequent opportunities of noticing.

Another reason why I believe, that manures act better, if spread on the surface of land, than when buried under it in the customary manner, *is*, that in the first case, the rain water carries the dissolved substances no deeper than the roots of most of our cultivated plants always grow, unless they are forced out of their natural course; and there these substances remain fast held by the earth's chemical affinity, until the stronger attraction of the spongioles of the roots begins to act upon them. But in the second case, that is, where manure is ploughed under as soon as spread, all the food of plants contained therein, being placed at once quite as deep as their spongioles naturally grow, and this too, before the rains begin to dissolve it, the subsequent solutions caused thereby, necessarily sink still deeper, and generally beyond the reach of the plants for whose nourishment they are designed. In no other way can I account for the long noticed and invariable superiority of crops produced by surface spread manure, to those produced by that which was ploughed in. To me there appears to be but this alternative, either to deny the facts already stated, which I myself have often witnessed, or to explain them, (if we must theorise on the subject at all,) in some such way as the one which I have just offered to your subscriber, and to such others of our brethren as may choose to examine it. Permit me further to add, that on this subject nature herself seems to offer us a useful lesson, if we were not too wise in our own conceits to be taught by such an instructress; for I know not a single exception to *her* practice of depositing on the earth's surface, all the putrescent substances of every nature and kind, which appear designed to preserve her fecundity.

In close connexion with this subject, there is one other matter on which I will take the liberty to express an opinion, although your subscriber has not asked for it. This is, in regard to the best state in which manure can be applied. So far as my own experience enables me to judge, an experience confirmed by that of many others in whose practical knowledge of the subject I have great confidence, I believe that the fresher it is, the better; for in such state, so much less will suffice, than in any more advanced stage of putrefaction, that time, labor, and value are all saved in the application: while none of the alledged "*burning*" ascribed to the manures being "*too hot*," ever occurs, if the quantity used be lessened in proportion to its freshness. This injury to plants, if I mistake not, is always caused by *excess* in the quantity, and not by the *quality* of the manure we apply to them, although the two things are often confounded, and thereby contribute to the perpetuation of error in regard to the nature and operation of all fertilizing substances. There is not, I believe, an agriculturist of any experience in our country, who has not had frequent opportunities of witnessing numerous facts to prove the correctness of these opinions. But, as I before remarked, we are all vastly fonder of our own fancies, than of facts in opposition to them; and consequently pass all such without notice, or, when too strong and obtrusive to be entirely disregarded, we spare no labor nor pains to force them, as far as we possibly can to subserve some previously conceived notion which our silly pride forbids us to abandon. This obstacle to the progress of all improvement, but especially in husbandry, is one of the most pernicious of our besetting sins; and *but for this*, it seems to me impossible that any controversy should still exist in regard to the best manner and state in which to apply manures to land. Two or three years, at most, would have been amply sufficient to establish the most beneficial practice, if all those whose special interest it is to ascertain it, would have diligently and impartially resorted to comparative experiments, accurately and assiduously made for the purpose, rather than to speculating and theorizing about it. But it can never be too late to make such experiments. Let me therefore, most earnestly, but respectfully recommend to your subscriber, who has done me the honor to ask my opinion, as well as to all others who may still have doubts on the subject, forthwith to commence making trials of the different methods of applying manures, and also of the different states in which it is applied. The opinions of experienced men are certainly well worth consulting, in regard to all matters connected with their respective trades, professions or callings; but we should never implicitly take them as guides for our own practice, any longer than until we can have leisure to test their correctness by actual experiments. When a number of these concur in producing the same uniform result, it is a matter of very little comparative importance, how others may endeavor to account for the fact, as the fact itself is the all important thing, especially in every practical art. But this war between speculation and practice, between nature's own doings, and our fanciful ways of accounting for them, is destined, I fear, never to cease, so long as such a thing remains in the world, as pride of opinion. Let a man once commit himself so far, either in speaking or writing, as publickly to deliver what he considers an argument in support of his "ipse dixit," and there are a hundred chances to one that he persists in it to the day of his death.

In thus complying with your subscriber's request, I may perhaps have said more than either he or you expected or wished. If I have done so, I must rely for my excuse, on the proverbial garrulity of old age, unless your own kind feelings will suggest a better. I remain, dear sir, yours very respectfully,

JAMES M. GARNETT.

On Road Making.

South Lee, Mass. June, 1839.

Judge Buel—Sir—The improvements in the science of road laying and building, in the March number of the 6th volume of the Cultivator, I highly approve of, so far as it is carried; and if no better system is proposed you will make such use as you please of the following suggestion: Let the road in its construction imitate or copy the rail-road as near as practicable; that is, keep the wheels level, and go with an inclined plane from one bar or breakwater to another, and make the bars as seldom as the safe keeping of the road will admit; but when necessary, make them efficient, with permanent materials with from two to three feet rise, according to the levelness or pitch of the ground, always making provision for both wheels to rise simultaneously, never allowing the travel to sink from the summit of the break, below the natural descent of the land; and also never allow an oblique bar to be made on the travel, for that throws the load upon one wheel or side, which racks or strains the vehicle, jeopards a high load, strains the animals, discomposes the passengers and deranges the whole concern; whereas, when a road is built as above, should accidents happen from restive animals or other causes, you are far less exposed to upsetting than when oblique breaks are in the formation of the road. Having realized the folly of the general practice in road building, and witnessed the vast amount of funds wasted by thoughtless road commissioners, or surveyors of our highways; and where the experiment has been made, I have seen it conclusively demonstrated, that from fifty to seventy-five per cent have been wholly thrown away by unscientific overseers; therefore I approve of large districts being apportioned to men of liberal minds, in building as well as in locating our common highways, as a means to avoid the evil consequences which often arise from a limited selfishness, which operates to the mutual disadvantage of the taxpayer and the traveller. Yours, &c. A RECENT SUBSCRIBER.

Heavy Sheep.

Spout-Run, June 14, 1839.

Hon. J. Buel—Dear Sir—Since your readers are chiefly agriculturists, the following notice may be somewhat interesting in the Cultivator.

When the sheep at Spout-Run were sheared, on the 18th of May, a yearling ram and five of the ewes were weighed, as follows: ram 174 lbs. his fleece 5 lbs; 1st ewe, 196 lbs. fleece 5 lbs; 2d ewe, 174 lbs; 3d ewe, 190 lbs. fleece 7 lbs; 4th ewe, 164 lbs. fleece 5 lbs; 5th ewe, 164 lbs. her fleece 5 lbs; only two are considered at all above the average weight of the flock. The wool was clean washed, otherwise the fleeces would have weighed from 7½ to 11 lbs. and the ewes were all suckling lambs. These two considerations taken in view, it is believed to be the greatest exhibit of weight of carcass and fleece made in the United States by a flock of ewes. These sheep have been raised and improved by my friend, Mr. Ths. H. Burwell, of Spout-Run, Clark county, Va.—Respectfully yours, &c. A SUBSCRIBER.

The Farmer should Read and Think.

Schenectady, May, 1839.

J. Buel—Dear Sir—We learn from the most skilful anatomists, that the brain of all vertebral animals is of rapid growth and increase, from conception to birth, when the brain of all such animals in the scale below man, is complete and full as at maturity of age. Some evidence of this may be observed from their activity and facility of helping themselves to food, &c. With men it is otherwise, which may also be observed from his inability to do any thing for himself in infancy.

The brain in man, is also of the same rapid growth from conception, but is not complete at birth. It continues the same rapid increase in volume and improvement, till the seventh year of age, when it is also complete, and is fully developed, as at mature age, with little increase to seventy years. All the increase and volume of the brain after birth in man, is wholly wanting in all other animals. This fact shows plainly the beneficence of the great Creator, in bestowing on man greater gifts than on any of his creatures.

When the brain has become complete in man, at his seventh year, it is like a large blank book full of leaves, ready to receive impressions. He now becomes a moral being, with capacity for intellectual improvement, as well as physical. He is now to learn his relations to his God, as the great and beneficent giver; to himself, as the immediate field of operation; and to his neighbor, as the comfortable and convenient fellow associate, in the mutual uses and improvements of the immense good gifts of the great Creator in the relations here, and of the infinitely greater gifts and provisions for a better existence hereafter, beyond our vision, but of full and perfect faith.

From all these blessings, it must be evident to every rational and reflecting man, that all these superior gifts were intended to be improved and accounted for, like the talents bestowed by the "man travelling into a far country, who delivered to his servants his goods. To one he gave five talents, to another two, and to another one —and who, after a long time, returned and reckoned with them."—Mathew xxvi. 14, &c.

Can man, on whom such great bounties have been conferred, fulfil all his duties, by folding his arms in idleness? If he be rich in the good gifts of Providence —in wealth, health and intellect, shall he say that he has enough, as an excuse for indolence and ease? We read, "to whom much is given, of him much will be required;" and it will be with the highest justice, too.

But, farmers in general, have chosen to degrade their own occupation, by calling it a life of drudgery and ignrance—thinking it enough if they know the horse from the ox, can plough, sow their seed, swing the axe, the scythe and the cradle in harvest. They should recollect, that the first and most honorable employment appointed by God to man, was to dress the flower-garden, and till the ground. And shall man despise this noble employment, under such authority and profit, and call it degrading? He does so, and it is because he is idle, and ignorant of the great gifts, of almost infinite uses of application in science, in the performance of the various duties of the good husbandman.

To be a good and profitable farmer, requires the man to be as scientific, as to be the good and skilful physician. He is to learn and understand that all vegetables must feed, as well as all animals do. He should learn how they feed, and on what aliment they thrive most rapidly.

When the farmer has acquired sufficient knowledge in botany and chemistry for profit, to guide him in his husbandry, he will know that all living substances, that is, all organic bodies possessing the gift of life, whether of the animal or vegetable kingdom, must derive their sustenance from organized matter, that is, from animal or vegetable bodies in a state of decomposition after death. The earth is a scene and foot-path for locomotives, in seeking their food and pleasure. It is the footstool and support of the vegetable tribe. No animals or vegetables can derive nutriment from other living organized bodies. The stomach of no living animal has any digestive power over any living animal or vegetable in it. But, so soon as life is extinct, all animal and vegetable matters, become food, to digest and nourish all living organized bodies, both animal and vegetable.

Although the human stomach has no digestive power on living matter, yet its own gastric secretions will digest even its own, the same stomach that secretes it, so soon as the subject is dead. The living principle protects all living bodies from decomposition and digestion. But the moment the living principle has departed and become extinct, it is subject to both decomposition and digestion. So the vegetable feeds on decomposed animal and vegetable matter, as does the animal kingdom.

All the nourishment of animals and vegetables is derived from organized matter, that is, from matter once possessing the living principle, and that has suffered death, or the cessation of the living principle. The air, water, lime, alkali, caloric, silex, phosphorus, carbon, light, oxygen, hydrogen, nitric and electric fluids, and the thousand other fluids and gases yet beyond the knowledge of man, all lending their aid in promoting animal and vegetable life and growth, the earth being the vehicle and support.

What a wide field is here opened to the vigilant and intelligent farmer! And will the husbandman continue to waste his leisure hours of morn and eve, and rainy days in idle talk and sleep, when his profession suffers so great loss from his ignorance?

If the farmer would begin to read, he would soon acquire a taste for reading more; and his thirst for science would urge him to notice that most valuable injunction, "gather up the crumbs that nothing be lost." How many crumbs of time are lost to the farmer, which, if employed in reading, would make him intelligent and honorable among men, and skilful in his occupation. Can all this useful knowledge of the growth of vegetables be understood by the self-sufficient, but ignorant farmer?

To become a scientific and successful husbandman, requires more knowledge in natural science, than to be the most improved mechanic. Although the skilful mechanic must learn the principles and rules of his operation from the laws of nature, by reading, and the application of industry, yet his task is more easy, because more visible and tangible.

The husbandman, although he cannot perfectly understand the process by which his vegetables increase in growth, yet he sees that they have grown and produced a rich load, and he reaps the most bountiful harvest from his improved and scientific cultivation. The numerous reports of scientific farmers, recorded in the Cultivator, prove this.

The principles of husbandry must be the same every where; but different soils and different climates require a diversity of treatment and culture. All these man must learn by science and experiment; for that law, that he "shall eat his bread by the sweat of his brow," has not been repealed. Nor will Divine Wisdom ever repeal that law, because it is not for man's good to be idle. If he were not obliged to labor, he would soon perish in filth and sloth, and not learn gratitude to God, who gives him all things richly, in goodness and mercy.

I must defer saying more till another opportunity, as this will occupy too large a space in your useful Cultivator, to the exclusion of more interesting matter. Respectfully. DAVID TOMLINSON.

Whitington New White Wheat.

Albany, July 13th, 1839.

Mr. J. Buel—Dear Sir—In the month of March last, I received from my brother Geo. C. Thorburn, two bushels Whitington New White Spring Wheat; from the high recommendation the wheat received at the Liverpool Agricultural Society of England, and its fine appearance, (a large white plump grain,) I was induced to recommend it to our farmers, and would not sell over two to four quarts to any one person, (except in a few instances,) in order to give this wheat a wide circulation through our country. I have reason to fear, it is a *winter wheat.* From the circulars sent from England *with the wheat*, I sold it in *good faith* as a *spring grain;* I never gave it any other recommendation than its appearance, and the testimony of the grain in England. In the April or May number of the Cultivator you made an extract of the qualities of the wheat, from an English work, and from your notice of it, I received orders from all parts of our country, for a few quarts of the wheat. No one regrets the disappointment more than myself, and I here disclaim any intention of practising a deception on the public, and am willing to render every satisfaction in my power. Respectfully yours, &c. W. THORBURN.

BY THE CONDUCTOR.

In the December number of the London Farmer's Magazine, we saw advertised, "*the Whitington New White Wheat*, for winter or *spring* sowing, which obtained a medal at the Liverpool Agricultural Meeting in 1836." We received a sample of the most handsome wheat we ever saw, which purported to be the Whitington; in consequence of which, and of its being represented to be a spring wheat, we sowed one bushel, early in April. But it evidently is a winter grain; as only an occasional plant shows an indication of producing seed at this time, July 15. We are satisfied that the Messrs. Thorburns, as well as ourselves, have been imposed upon, by the foreign advertisements and circular which accompanied the wheat from London. We purpose to mow ours, in the hope of getting a crop from it in 1840.

Observations on Magnesia as a Manure.

Considerable prejudice exists, I believe, against the use of magnesian limestone as a manure. This originated in the experiments of Mr. Tennant, who, on examining a lime long known to the farmers at Doncaster, in England, as injurions to their crops, found that it contained magnesia. In order to certify the truth of his examination, he mixed some *calcined* magnesia with soil, on which he sowed different seeds; and the result was, that they either died or vegetated in a very imperfect manner, and the plants were never healthy.

I have taken this statement from Sir Humphrey Davy's Agricultural Chemistry; and you will find that while he concedes the correctness of Mr. Tennant's opinion, he at the same time gives sufficient reasons for believing that magnesian limestone, or carbonate of magnesia, may prove fertile. One of the most fertile districts of Cornwall, the Lizard, is a district in which the soil contains mild magnesian earth.

Still, the prevailing opinion down to the present day has been unfavorable to magnesia, and this in the face of the well known fact, that most good soils contain a suitable proportion of it. It has lately been announced by Professor Giobert, that in the vicinity of Castellmonte, (in Italy, I presume,) this earth is abundant in the soil which is most fruitful. And he adds, that there are numerous localities in Piedmont, of a similar description. He hence infers, that native carbonated magnesia is not injurious to vegetation; and again, that in consequence of the solubility of magnesia, in an excess of carbonic acid, this substance may exercise a fertilizing power similar to carbonate of lime.

If these facts be correct, it is reasonable to suppose, that magnesia is taken up by plants, and an Italian chemist named Abbene, has actually detected it in the ashes of such as had grown in magnesian soils.

The practical deduction from these observations is the following:—If the magnesia in the soil, or the magnesian limestone, after being burnt, appears too caustic, add compost sufficient to furnish the needed carbonic acid. And the sterility of magnesian soil is to be attributed to its cohesion and want of proper mixture of other ingredients, rather than to the peculiar earth.

These observations are condensed from a French periodical of January, 1839, in the hope, that they may be found useful to some of your readers. T. R. B.

Extirpation of Garlic.

Montculm, Va. June 21st, 1839.

J. Buel, Esq.—Sir—The extirpation of wild garlic has been regarded rather as an object to be desired by the agriculturist, than one to be successfully accomplished. An experiment, made by myself, not with that view, however, will at least point out one mode by which this unpleasant plant may be destroyed. In one-third of a field of about twenty acres, it had become very thickly set. In the summer of 1836, the wheat grown on this part of the field was so filled with it, that I was induced to keep it separate from the rest, to prevent its injuring the sale of the whole. The next spring, 1837, I planted the field in corn, and in the fall, having a large number of hogs to fatten, and no time or labor to spare to gather corn for them, I turned the whole of them into this field. (This is sometimes done in this part of Virginia.) They remained here till they had nearly consumed all the corn, when they were removed into small pens and fed. I then turned all my store hogs into the field, to finish what was left, where they remained till late in December. In the mean time, as their food decreased, I commenced feeding them once, and afterwards twice a day, during the winter. They were permitted to have access to the field for half the winter. My feeder, in December, told me that they were eating the garlic. In the spring, I sowed the field in oats and clover. The oats were good; the clover was destroyed by the burning drought of last summer; thus leaving the field entirely naked. I then determined, (last fall,) although the fourth crop in succession, to sow it in wheat, which I did, and this spring in clover and timothy, a full quantity of each. Now, sir, I have, in the last fortnight, repeatedly and carefully searched for the garlic, and found two stalks only, where thousands stood before. The garlic is now in full bearing, and may be easily detected.

It is manifest that this method of destroying this pest will not generally answer. But the idea may be improved on. If a farmer have but one field of corn, and garlic prevails in it, he may gather nearly the whole of it, and instead of seeding it, as is the usual practice, let him turn in all his hogs, that are to be kept over to the next year, and they will soon get hold of the roots, &c. He will then put in a spring crop with grass seed. So well satisfied am I with the result, in this case, that I shall pursue the same plan in respect to two other fields, in which there is a good deal of garlic. It will occur to you, that the ground being light and mellow, from the recent cultivation of the corn crops, the hogs have no difficulty in finding the bulbs, which they will not attempt in a field well set in grass or stiffened with a sod, although abounding in garlic, and this for two reasons: they have a plenty to eat, and with less labor. Yours, &c. JAS. McILHANY.

EXTRACTS.

Diseases of Sheep.

The surgeon who operates upon the human system, is presumed to know, and ought to know, something of anatomy, in order to enable him to discover the seat and cause of disease, that he may more readily apply the needful remedy. The structure of the brute is nearly as complicated as that of man; and the same degree of professional skill is often as necessary in managing rightly the diseases of the one as the other. There are more quacks in the veterinary art, than in the profession of surgery; and it therefore stands the intelligent breeder in hand, to qualify himself to become, in some measure, his own cattle doctor. To aid him in this useful study, we make the following extract. A vast many sheep are lost by diseases of the foot. The nature and seat of these diseases, are pointed out with such plainness, and the modes of prevention and the means of cure are so briefly described, that any intelligent sheep master may make the whole subject familiar to his mind, and be able to practise with confidence and success upon his flock.—*Conductor.*

[*From the Library of Useful Knowledge, Farmers' Series.*]

DISEASES OF THE FOOT.

The dreadful and too frequent disease termed foot-rot belongs to the present chapter. There are two varieties of it, or rather there is a disease of the foot, properly speaking, and of the fetlock and pastern-joints.

DISEASE OF THE PASTERN, OR BIFLEX CANAL, AND FETLOCK-JOINTS.

The fetlock of the sheep, like that of the ox, is a very complicated joint. There are two pastern-bones in each leg, articulating with the canon or shank-bone. The leg bone itself is double in the fœtus, but the cartilaginous substance between the two portions of it is afterwards absorbed, and they become one large bone. The lower bones, however, continue separate, and each division has its own ligaments and tendons, and is covered by its own integument. The whole of the fetlock-joint is weakened by this division, and each of the pasterns below is also materially weakened.

At the portion of the skin immediately over the point of bifurcation of the pasterns, there is found in the sheep and in the goat a small orifice called the biflex canal, because it is common to both of the pasterns. It is formed by a fold of the skin, and immediately within the skin it bifurcates, and a canal or tube runs down on each side over the inner face of the pastern, reaching to the coronary ligament at the commencement of the hoof. It contains a great number of follicular sebaceous glands, which secrete a yellow strong-smelling mucous fluid. At the bottom, this canal curves upon itself and terminates in a blind pouch or cul de sac. The superior orifice, always open, is marked by a little tuft of hairs growing from it, and often agglutinated together by the perspiration of the part, or by the adhesive discharge from the canal. The function or use of this singular pouch has never been satisfactorily explained. It may answer two purposes—it may contribute to the suppleness, or freedom of motion of the pasterns, and enable them to adapt themselves to the irregularities of the ground and share the weight of the animal equally between them, or it may secrete a bland and evaporating fluid, which will be in contact with the pastern and joints of the foot in cases of sprain and injury.

Whatever may be the function of the canal it is sometimes the seat of considerable disease, which has been confounded with foot-rot, and which " in common parlance," is here described as a variety of it.

An accumulation of this sebaceous fluid in the biflex, intergidital canal, or the introduction of foreign bodies into it, such as dust, dirt, or gravel, may cause a considerable degree of local inflammation, and which may be communicated to the neighboring parts. Diseases of this canal are of most frequent occurrence when the flock is turned on hard, dry, or sandy pastures. Heavy and fat animals are, as might naturally be supposed, most subject to its attacks; sometimes in every season of the year, but oftenest when the weather is hot and dry. The great number of sheep that have been attacked by it at the same time, and especially as it has been so generally confounded with foot-rot, have excited the suspicion that it is infectious. There does not, however, appear to be any ground for this supposition.

The inflammation is first discovered by the lameness of the sheep, which probably leads to an examination of him, when the part is found to be hot and tender, with some enlargement. If the animal is neglected, the swelling will, probably in a few days, reach the pastern and the coronet below, and the fetlock and the leg-bone above, and to this will follow ulceration of some part of the biflex canal, which will speedily become a source of great annoyance and mischief. The pus penetrating inferiorly will find its way under the coronet, and produce quittor, or even loss of the hoof on the affected side; sometimes ulcers will appear about the fetlock.

Generally speaking, the disease attacks only one foot, and then the sheep goes about on three legs. If both fore legs fail, he must be content to crawl about on his knees. The biflex canal is found in all four feet, but it is comparatively seldom that the hind feet are diseased. The poor animals evidently suffer a great deal, for they scarcely feed—rumination is suspended—fever is established, and, in some bad cases, the sheep pines away and dies.

Before the disease has gone so far as this, the proprietor, acting humanely and wisely, should send the animal to the butcher. The note at p. 524 has already explained the once common opinion respecting this complaint—namely, that it was caused by a worm that had eaten its way into the leg, the hole through which it had entered being still visible. According to this doctrine, the only means of cure lie in the removal or destruction of the worm.

The treatment in the early stage of this disease consists in the extraction of any foreign bodies that may have insinuated themselves into this canal, and in fomenting the part and the whole of the foot. These lotions should be followed by a poultice enveloping the whole foot and the greater part of the leg—an emollient poultice at first, and until the discharge of purulent, and perhaps fetid, matter is staid, and then an astringent one. A decoction of oak bark will form a good liquid for the poultice. In very bad cases, local bleedings (scarifications) round the coronet are practised with considerable advantage. Any tendency to gangrene is combatted by a solution of the chloride of lime.

A cure, however, will not often be accomplished by these means, except where there is no actual disorganization of the biflex canal. If that should have taken place it will be necessary to lay it open or remove it, and when it is dissected out, thickened by inflammation and with its singular natural tortuous form, the older shepherds will readily be forgiven for endowing it with life and the power of producing almost irreparable mischief. The French strongly recommend the removal of this singular reservoir, but that will not always be necessary. The orifice into the canal may be somewhat enlarged, and a probe-pointed bistoury thrust into that division of it which is most or alone affected, or a small seton needle may be introduced, and brought out just above the coronet. Either of these operations, and especially the latter, will usually succeed. The wound, if the bistoury has been used extensively, should be daily dressed with digestive ointment for a while, and which should be afterwards changed for the tincture of myrrh; the old butyr of antimony not being forgotten if the case seems to require it.

FOOT-ROT.

Foot-rot is a disease always at first, and usually throughout its whole course, confined to the foot. The first indication of foot-rot is a certain degree of lameness in the animal. If he is caught and examined, the foot will be found hot and tender, the horn softer than usual, and there will be enlargement about the coronet, and a slight separation of the hoof from it, with portions of the horn worn away, and ulcers formed below, and a discharge of thin fetid matter. The ulcers, if neglected, continue to increase; they throw out fungous granulations, they separate the hoof more and more from the parts beneath, until at length it drops off.

All this is the consequence of soft and marshy pasture. The mountain or the down sheep—the sheep in whose walk there is no poachy ground, if he is not actually exposed to infection by means of the virus, knows nothing at all about it; it is in the yielding soil of the low country that all the mischief is done.

In attempting to explain this, the author cannot do better than to have recourse to much of the beautifully graphic description of the healthy foot of the sheep and the changes which it undergoes, as given by his talented and excellent friend, Professor Dick, of Edinburgh.

The foot presents a structure and arrangement of parts well adapted to the natural habits of the animal. It is divided into two digits or toes, which are shod with a hoof composed of different parts, similar in many respects to the hoof of the horse. Each hoof is principally composed of the crust, or wall, and the sole. The crust extending along the outside of the foot, round the toe, and turning inwards, is continued about half-way back between each toe on the inside. The sole fills the space on the inferior surface of the hoof between these parts of the crust, and being continued backwards becomes softer as it proceeds, assuming somewhat the structure of the substance of the frog in the foot of the horse, and performing, at the same time, analagous functions. The whole hoof, too, is secreted from the vascular tissue underneath.

Now this diversity of structure is for particular purposes. The crust, like that in the hoof of the horse, being harder and tougher than the sole, keeps up a sharp edge on the outer margin, and is mainly intended to resist the wear-and-tear to which the foot of the animal is exposed. The soft pasturage on which the sheep is occasionally put, presents little, if any, of that rough friction to which the feet of the animal is naturally intended to be exposed. The crust, therefore, grows unrestrained until it either laps over the sole, like the loose sole of an old shoe, and serves to retain and accumulate earth and filth, or is broken off in detached parts; in some cases exposing the quick, or opening new pores, into which particles of earth or sand force their way until, reaching the quick, an inflammation is set up, which, in its progress, alters or destroys the whole foot.

The finest and richest old pastures and lawns are particularly liable to give this disease, and so are soft, marshy, and luxuriant meadows. It exists to a greater or less extent in every situation that has a tendency to increase the growth of the hoofs without wearing them away.

Sheep that are brought from an upland range of pasturage are more particularly subject to it. This is very easily accounted for. By means of the exercise which the animal was compelled to take on account of the scantier production of the upland pasture, and also in consequence of the greater hardness of the ground, the hoof was worn down as fast as it grew, but on its new and moist habitation the hoofs not only continued to grow, but the rapidity of that growth was much increased, while the salutary friction which kept the extension of the foot within bounds was altogether removed. When the nails of the fingers or toes of the human being exceed their proper length they give him so much uneasiness as to induce him to pare them, or if he neglects this operation they break. He can pare them after they have broken, and the inconvenience soon ceases, and the wound heals. When, however, the hoof of the sheep exceeds its natural length and thickness, that animal has no power to pare them down, but there long continues a wound, irritated, and induced to spread, by the exposure of its surface, and the introduction of foreign and annoying matters into it.

The different parts of the hoof, likewise, deprived of their natural wear, grow out of their proper proportions. The crust, especially, grows too long; and the overgrown parts either break off in irregular rents, or by overshooting the sole allow small particles of sand and dirt to enter into the pores of the hoof. These particles soon reach the quick, and set up the inflammation already described, and followed by all its destructive effects.

There is another circumstance which tends to produce disease in an overgrown hoof. The length to which the crust grows, changes completely the proper bearing of the foot, for being extended forward, it takes the whole weight of the superincumbent parts. By the continual pressure on this lengthened part, inflammation cannot fail of being set up. The progress of the disease is not equally rapid in every instance; sometimes it goes to a certain extent, and the foot to a considerable degree recovers. All the feet may not be equally affected; the fore ones, however, are always the most liable to disease, on account of the additional weight which they carry. Sometimes there is only one foot affected, and that is sure to be a fore one—sometimes only one hoof of one foot, and occasionally one speedily heals while the other continues to get worse and worse.

In the first stage of the disease there is often found nothing but a little overshooting of the edge of the crust, and which is bent in upon the sole, or the edge of the crust is forced asunder from the sole and a wedge of earth is introduced which presses upon the sensible substance beneath; but at other times the edge of the crust continues to grow until it envelopes the whole of the sole. It is seldom that there is inflammation enough excited to throw off the whole hoof at once; but it separates at different parts, and at each part of separation there is new horn formed; this although soft and unhealthy, and not capable of sustaining pressure, covers, and to a certain degree, protects the sensible parts beneath. By degrees, from increased and long-continued irritation, the parts are no longer able to secrete even this weak horn, but granulations of proud flesh sprout out, and then the work of destruction proceeds in good earnest.

This is the usual progress of the disease, but at other times inflammation seems to be set up at once over the whole of that division of the foot, and there is considerable swelling about the coronet, and matter is formed and breaks out, and sinuses run in various directions, and the whole of the hoof is gradually detached. The upper part of the space between the hoofs becomes inflamed and swelled, the whole of the inner surface of the pastern is sore and raw; ulceration commences—it eats deeply—it spreads on every side—it spreads upwards—and the toes are separated from each other almost to the opening of the biflex canal. That canal becomes inflamed—proper inflammation of it is added to that of the sensible parts beneath the hoof—the mucous follicles which it contains, and of which mention has been made, pour out a large quantity of sebaceous discharge, which flows over the fore part of the foot and between the hoofs, and assists in the accumulation of filth by its adhesiveness. In some cases, as has appeared when the diseased state of this canal was examined, the malady commences here. Inflammation of the biflex canal produces much enlargement of the neighboring parts, and the motions of the foot are interfered with, and inflammation and disorganization spread on every side. As these increase, and also the discharge by which they are accompanied, dirt and gravel, and pieces of grass adhere to the ulcerated surface, and insinuate themselves between the pasterns, there soon become one uniform mass of disease.

The ulceration of foot-rot will not long exist without the addition annoyance of the fly. Maggots will multiply on every part of the surface and burrow in all directions. To this, as may be readily supposed, will be added a great deal of constitutional disturbance. A degree of inflammatory fever is produced. The animal for a while shifts about upon its knees, attended by some faithful companion that abandons it not in its utmost need; but at length the powers of nature fail, and it dies from irritation and want.

This is a dreadful account, and yet, after all, the disease is more manageable than could well be imagined, if it is attacked in its earliest stage and treated with proper decision. It will seldom be necessary, or indeed proper, to adopt any means for the purpose of abating inflammation before the radical mode of cure is adopted. Poultices and emollients will only weaken the parts, and cause the fungous granulations to increase with tenfold rapidity.

The foot must be carefully examined, and every portion of loose and detached horn pared off, even though the greater part, or almost the whole of the hoof may be taken away. The horn once separated from the parts beneath will never again unite with them, but become a foreign body, and a source of pain, inflammation, and fungous sproutings. This, then, is the first and fundamental thing—*every portion of the horn that is in the slightest degree separated from the parts beneath must be cut away.* A small, sharp, curved-pointed knife, or a small drawing knife, will be the best instrument to effect this.

If there are any fungous granulations they must be cut down with the knife or a pair of sharp curved scissors, unless they are exceedingly minute, and then the caustic about to be mentioned will destroy them. The whole foot must be thoroughly cleaned, although it may occupy no little time, and inflict considerable pain on the animal. The after expenditure of time, and the suffering of the patient, will be materially diminished by this decisive measure.

The foot should then be washed with a solution of chloride of lime, in the proportion of one pound of the powder to a gallon of water. This will remove the fœtor, and tendency to sloughing and mortification, which are the too frequent attendants on foot-rot. The muriate or butyr of antimony must then be resorted to, and by means of a small stick with a little tow tied round one of its extremities, applied to every denuded part: lightly where the surface has a healthy appearance, and more severely where fungous granulations have been cut off, or there are small granulations springing up.—There is no application comparable to this. It is effectual as a superficial caustic; and it so readily combines with the fluids belonging to the part to which it is applied, that it quickly becomes diluted, and comparatively powerless, and is incapable of producing any deep or corroding mischief. So far as these foot cases are concerned, it supersedes every other application. The change of colour in the part will accurately show to what portions it has been applied, and what effect has been produced.

If the foot has been in a manner stripped of its horn, and, especially, if a considerable portion of the sole has been removed, it may be expedient to wrap a little clean tow round the foot, and to bind it tightly down with tape, the sheep being removed to a straw-yard, or some enclosed place, or to a drier pasture. This last provision is absolutely necessary when the sheep is again turned out; for if the foot is exposed to the original cause of disease, the evil will return under an aggravated form.

The foot should be dressed every day; each new separation of horn removed; and every portion of fungous submitted to the action of the caustic, with a degree of severity proportioned to the necessity of the case. The new horn should likewise be examined. If it appears to be healthy and tolerably firm, nothing should be done to it; but if it is soft and spongy, the caustic must be lightly applied. The sooner the bandage can be removed, and the sheep turned into some upland or thoroughly dry pasture, the better will it be for the foot, and the health of the animal generally.

The worst cases of foot-rot will readily yield to this mode of treatment, provided the bone has not been exposed, and there are no sinuses running either into the joints or deep-seated parts of the foot, or of the pasterns above. All superficial mischief will be readily repaired, and more speedily than could have been thought possible; but there is always a considerable degree of uncertainty, when the horn being removed, the ulcerations are found to be deep, and certain sinuses or openings betray the existence of greater mischief within the foot. The case will, at all events, occupy a considerable time, and give no little degree of trouble; and it will be for the owner to consider whether he had not better destroy the sheep if he is in tolerable condition, than to run the risk of his pining away, and ultimately sinking under long-continued and increasing suffering.

The sheep that has been attacked by foot-rot should not be suffered to rejoin his companions while there is the slightest discharge from any part of the foot. This goes on the supposition that the foot-rot may not only be produced by the causes that have been mentioned, but that the discharge from the sores and sinuses is of an infectious nature. Some valuable writers, and Professor Dick among the number, have denied the infectiousness of foot-rot. They find sufficient reason for the spreading of this disease through a whole flock, from all the animals having been exposed to the same exciting cause; the feet of all of them having been macerated by the soft and damp pasture on which they have trodden, and the internal part of the foot being thus denuded and injured.

There cannot be a doubt on which side the preponderance of evidence lies, and the question would not have been entered into at so great length were not the settlement of it so essentially connected with the interest of the sheep-breeder. It is produced in certain individuals of the flock, by the process of maceration and softness which the hoof undergoes on the moist surface of certain pastures; but once set up, an ichorous and venomous fluid is secreted, by which the disease is too surely and rapidly spread. "In all situations where it has obtained a footing," says Mr. W. Hogg, "we find it beginning in a particular place, and, if unopposed extending wherever there are sheep to be affected by it."

It has been said that the manner in which the contagion is conveyed has not been satisfactorily explained. There is no necessity, however, to have recourse to any epidemic influence, or to any constitutional affection produced by feeding on the grass on which the virus has been deposited. The account that has been given of the state of the foot, its degree of maceration, the opening of all its pores, the frequent laceration of the horn, and the absolute exposure of a greater or less portion of the sensitive substance of the foot, the frequent inflammation, and sometimes ulceration of the thin skin which covers the coronet,—all these circumstances afford means more than sufficient for the absorption of the virus and the production of the disease.

Some persons have imagined that foot-rot is propagated by means of animalculæ which are bred in the virus of the part, and falling on the pasture, attack the feet of other sheep. They have gone so far as to describe this insect, and to give it a name—*the pulex penetrans*. The author of this work has often sought for it in vain; and the sources of contagion are numerous and satisfactory enough, without any gratuitious supposition of this kind.

The establishment of this cause of the disease leads to an evident and an effectual mode of prevention; the removal of every sheep that begins to halt, and before the secretion of the virus has commenced. It is bad policy to let the poor animals crawl about the pasture on their knees, day after day; and the sheep-owner will severely suffer for his folly. How long a pasture may be considered to remain tainted it is impossible to decide; but a heavy rain or sharp frost would probably wash the virus away, or destroy its power. The sheep that are removed should not be permitted to return until their feet are perfectly healed, and have been well washed.

The previous habits of the sheep would have a more decided influence in the production of foot-rot. Supposing different lots of sheep were taken from a dry upland pasture, and placed on a moist and richer soil; the consequence would be that the hoofs of all would be macerated and softened, and exposed to injury, but that injury would be proportionate to the pressure upon and the wear of the foot. That was a very interesting account which was given by Mr. Black, p. 532, of the progress of foot-rot among certain sheep of different kinds, that had been turned into one of the parks. The black-faced sheep were first affected, and to the greatest degree; next in degree was a cross between the black-faced and the Cheviot; then the Cheviot, and, last and least of all, the Leicester breed. "I was at a loss," says he "to account for this peculiar liability in the different breeds, while all were exposed to the same circumstances; but by carefully watching the flock, I found that the black-faced got up from their lairs the earliest in the mornings, and from their being accustomed to roam from the hill to the glen at the approach of daylight in search of their food, continued from habit to wander through the park before they began to feed. The other breeds possessed this disposition precisely in the order in which the disease appeared. Consonant with this is the common remark, that Southdown sheep, removed from their native downs to low and moist pasture, are peculiarly subject to foot-rot. A most useful conclusion will naturally be drawn hence, as to the kind of sheep that should be selected for different soils and pastures.

As the foot-rot proceeds from the distorted form of the hoof, and the irregularity of the pressure, more than from the simple wearing away of the softened horn, it might be useful, and especially on suspected ground, to pare the feet of all the sheep twice in the year—in October or November, and April or May, taking advantage of a wet day or two, when the horn will be more than usually soft. If there should be the slightest appearance of unsoundness at these periodical parings, the proper applications should be made to the feet.—The sheep might occasionally be folded on some bare and hard spot, or driven twice or thrice in the week a little way along the road. Prevention would in this, and many other cases, preserve the animal from disease and torture, and the owner from expense and loss.

Of the Nature and Action of Manures.

[*From Chaptal's Chemistry applied to Agriculture.*]

Under the general head of manures are comprehended all those substances which, existing in the atmosphere or combining with the soil, can be drawn in by the organs of plants, and contribute to the progress of vegetation.

Manures are furnished by various bodies belonging to the three kingdoms of nature. Those most commonly employed are the results of decomposed vegetable substances, and some animal matters.

The salts, which likewise serve for manures, are imbibed by the pores of plants, and serve to stimulate vegetation.

By comprehending all these substances under the generic name of manures, too extensive a signification is given to the word. I divide manures into two classes; and in order to deviate as little as possible from the customary mode of expression, I shall call those nutritive manures, which supply plants with nourishment, and all those which excite the organs of digestion stimulating manures. These last are, strictly speaking, the seasoning; the spices, rather than the food.

1. OF NUTRITIVE MANURES.

The nutritive manures are those which contain juices or other substances, which, being dissolved in water, or otherwise divided to the most minute degree, are capable of being drawn into the organs of plants. All the vegetable and animal juices are of this description.

These substances are rarely employed in their natural state for the aliment of plants. It is generally considered preferable to allow them to putrify or ferment;* the reason of this is simple. Besides the decomposition resulting from this operation, which renders the substances more soluble in water, the gases produced by it, such as the carbonic acid, the carburetted hydrogen, azote, and ammonia, furnish food for plants, or stimulants for their organs of digestion. It is not, however, well to prolong this decomposition too far; for if it be completed, there will remain only some fixed salts, mixed with those earths and juices which have resisted its action. Besides, the effect of manures, which have been entirely decomposed, is almost momentary, lasting but for a single season; whilst those which are employed before arriving at this state, continue to exert an influence for several years. In this last case, the decomposition, retarded by the separation of the manures into small portions, continues to go on gradually in the earth, and thus furnishes vegetation with its necessary aliments for a long time.

The excrements of animals, formed by the digestion of their food, have already undergone a decomposition which has disorganized the principles of their aliments, and in a greater or less degree changed their nature. The strength of the digestive organs, which varies in each species of animal, the difference of food, and the mixture of the digestive fluids furnished by the stomach, modify these manures to a very considerable extent.

The excrements of some animals, as of pigeons, fowls, &c. are employed without undergoing any new fermentation, because they consist mostly of salts, and contain but few juices. Fields are often manured with the excrements of sheep, collected in the sheep-folds, or scattered, as in parks, by the animals themselves upon the soil; but in general the dung of horses and of horned cattle is made to undergo a new fermentation before being applied as manure.

The most general method of producing the fermentation of the dung of quadrupeds, is, in the first place, to form upon the ground of sheep-folds and stables a bed of straw or dry leaves This bed is covered with the solid excrements of the quadrupeds, and impregnated with their urine. At the end of fifteen days or a month, it is carried to a place suited for fermentation, and there formed anew, care being taken every day to spread upon it litter and the scatterings of the racks. The formation of these beds, contributes much to the healthfulness of the stables and to the cleanliness of the animals.—When from a scarcity of straw, the beds cannot be made of sufficient thickness, or renewed often enough, a layer may be formed of lime or gravel, broken fine and covered with straw. These earths will imbibe the urine, and when they are penetrated by it may be carried into the fields to be buried in the soil. The nature of the earth, upon which beds are formed in sheep folds or stables, should vary according to the character of the soil which is to receive them, because, by attention to this, the soil may be improved as well as manured.—For argillaceous and compact earths, the layers should be formed of gravel and the remains of old lime mortars; whilst those of fat marl or of clayey mud should be reserved for light and dry soils.*

In some countries where good husbandry is much attended to, the floors of the stables are paved and slightly sloping, so that the urine flows off into a reservoir, where it is fermented with animal and vegetable substances, and used to water the fields at the moment when vegetation begins to be developed.

The art of fermenting dungs with litter is still very incomplete in some parts of France. In one place they let it decay till the straw is completely decomposed; in another they carry it into the fields as soon as it is taken from the stables. These two methods are equally faulty. By the first nearly all the gases and nutritive juices are dissipated and lost; by the second, fermentation, which can take place only in masses, will be but very imperfectly carried on in the fields, and the rains can convey to the plants only that portion of the nourishment afforded by the manure; which they can obtain by a simple washing.

The most useful art perhaps in agriculture, and that which requires the most care, is the preparation of the dung-heaps. It requires the application of certain chemical principles, which it is not necessary for me to explain, since it is sufficient to point out to the agriculturist the rules by which he should be governed in his proceedings, without requiring of him an extensive knowledge of the theory upon which they are founded.

Solid substances, whether animal, vegetable, or mineral, do not enter into plants unless they are previously dissolved in water, or are drawn in with that fluid in a state of extreme division.

Animal and vegetable substances which are by their nature insoluble in water, may, by being decomposed, form new soluble compounds, capable of furnishing nourishment for plants.

Animal and vegetable substances deprived by the action of water of their soluble particles, may, in the course of their decomposition, form new compounds susceptible of being dissolved. Of this I have given instances in speaking of mould.

That which renders the art of employing dung-heaps difficult, in proportion as it is useful, is, that some methods which are adopted occasion the loss of a part of the manure. In fact when the clearings of the farm-yard are carried fresh into the fields, and applied immediately to the soil, vegetation is undoubtedly benefitted by the salts and the juices contained in them; but the fibres, the fatness, the oils, remain inactive in the earth; and their final decomposition is slow and imperfect. If, on the contrary, the collections of the farm-yard be heaped up in a corner of it, the mass will speedily become heated, carbonic acid gas will be evolved, and afterwards carburetted dydrogen, ammonia, azote, &c. A brown liquid, of which the colour deepens gradually almost to black, moistens the heap, and flows upon the ground around it; all is by degrees disorganized; and when the fermentation is completed, there remains only a residue composed of earthy and saline substances, mixed with a portion of blackened fibre, and some carbon in powder.

In those places where they do not allow fermentation to arrive to this degree of decomposition, they still lose, by mismanagement, a considerable part of their manure.

The most common method is, to deposite in a corner of the farm-yard the dung and litter, as it is drawn from the stables, adding to the mass every time these are cleared, and allowing it to ferment till the period of sowing arrives, whether it be in spring or autumn, when it is carried upon the fields requiring it.

This method presents many imperfections. In the first place, several successive layers being formed, no two of them can have undergone the same degree of fermentation; in some it will have gone on for six months, and in others but for fifteen days. In the second place, the heap, being exposed to rains, will, by frequent washings, have parted with nearly all its salts and soluble juices. In the third place, the extractive portions of the lower and central parts of the mass, the mucilage, the albumen, and the gelatine, will be entirely decomposed; and, lastly, those gases which nourish plants, if developed at their roots, will have escaped into the air; and Davy has observed, that, by directing these emanations beneath the roots of the turf in a garden, the vegetation was rendered very superior to that in the vicinity.

---

* The arguments of Count Chaptal in favor of partially fermenting manures before they are applied, seem to rest wholly upon the supposition, that the fibrous and woody parts of vegetables do not readily become soluble in the soil. This conclusion will be correct according to circumstances. The refuse vegetable matters of common farm crops, as straw, stalks, &c. will decompose if burned in the soil, without any admixture, but with greater facility if mixed, as they are in the cattle-yard, with the dung and urine of animals, materials that have already undergone decomposition, according to the Count's showing, "which has disorganized the principles of their aliments, and in a greater or less degree changed their nature." And if these are not decomposed the first year, they are not lost, but, like the bone and the horn, they continue to impart their fertilizing influence for years. But if fermentation is permitted to go on in the yard, what *do* we lose? Why, according to our author, we lose the gases produced by it, "such as the carbonic acid, the carburetted hydrogen, azote and ammonia, [which] furnish food for plants, or stimulants for their organs of digestion." Under the fermenting process, we lose most of the active and valuable portions of the manure; under the mode of applying them in an unfermented state, we save these volatile properties, and ultimately lose nothing. The writer sets out with the proposition, that fermentation *should* precede the application of dung; but his arguments go conclusively to show, that fermentation should not precede its application. We suspect an error has here been committed, either in the translator or the printer; and that the proposition, like the proof, should stand in favor of unfermented, or but partially fermented manures—and not in favor of their being allowed to putrify or ferment.—*Cond. Cult.*

* These processes involve too much labor for our farmers; they innovate too much upon their customary habits; and are, withal, we think unnecessary, in the present state of our husbandry. A capacious concave cattle-yard will form the cheapest, if not the best, bed for a compost for dung, urine and litter; and fermentation will have sufficiently progressed in April or May, when the mass should be taken to the field, and buried by the plough, for the hoed autumnal ripening crops, to afford a full benefit to the crops.—*Cond.*

How long should dung-hills be allowed to ferment; and what methods ought to be pursued in forming them? This question leads us to cast a glance upon the nature of dunghills; and it is not till after having ascertained the difference amongst them, that it can be answered.

The principal parts of vegetables which are employed as manure, contain mucilage, gelatine, oils, sugar, starch, extractive matter, and often albumen, acids, salts, &c. with an abundance of fibrous matter, insoluble in water.

The different substances afforded by animals, including all their excretions, are gelatine, fibrine, mucus, fat, albumen, urea, uric, and phosphoric acids, and some salts.

The greatest part of the substances, constituting animals and vegetables, are soluble in water; and it is evident that in that state they can be employed as manures without previous fermentation; but it is necessary, that those which contain much insoluble matter should be decomposed by fermentation, because by that process their nature is changed, and they form new compounds, which, being capable of solution, can pass into the organs of plants.

Messrs. Gay-Lussac and Thenard have obtained, by an analysis of the woody fibre, oxygen, hydrogen, and especially more carbon, than from any other part of the plant, and they have determined their several proportions. We know that fermentation carries off much carbon; it is then evident that, by causing the fermentation of the vegetable fibre, the principle which forms its distinguishing characteristic will be gradually diminished, and that it will no longer be a body insoluble in water. It is in this manner that woody plants and the driest leaves are converted into manure.

But as all the solid parts of plants contain fibres which cannot be rendered soluble in water, but by a long period of fermentation; and as it is in the fibre that carbon, a principle so necessary to vegetation, chiefly exists, the fermentation of plants is indispensible to the procuring of the best part of their manure.

The custom of appropriating some crops whilst green to the manuring of the ground, may perhaps be objected to; but I have observed, that in that case the plants are buried in the earth at the time of flowering; and whilst they are succulent, and their fibres soft, and but little formed; and that warmth and the action of the water in the earth was sufficient to decompose them; this would not take place if the stalks were dried and hardened by the formation of the grain.

The dung of quadrupeds may be mixed advantageously with the earth at the time of being taken from the stable, if it contain no litter, but if it does, it appears to me better to cause it to undergo a slight fermentation, in order to dispose the straw or leaves of which it is composed to become manure.

It is necessary, in producing the fermentation of dung and litter, to use certain precautions by which the inconveniences arising from the usual mode may be avoided.

Instead of heaping up in large masses the collections of the barn-yard and stables, and allowing them to rot uncovered, and exposed to the changes of weather, they should be placed under a shed, or be at least protected from the rain by a roof of straw or heath. Separate layers should be formed of each clearing of the stables, cow-house, and sheep-pens. These layers should be from a foot and a half to two feet in thickness; and when the heat, produced in them by fermentation, rises in the centre to more than 95°, or when the mass begins to smoke, it should be turned, to prevent decomposition from going too far.

Fermentation should be arrested as soon as the straw contained in the heap begins to turn brown, and its texture to be decomposed. To do this, the mass may be spread, or carried into the fields, to be immediately mixed with the soil; or there may be mixed with it mould, plaster, turf, sweepings, &c.

When the dung is not of the usual consistency, as is the case with that of neat cattle during the spring and autumn, it ought to be employed immediately, as I have already stated; but if it be impossible to apply it to the fields whilst recent, it should be mixed with earths or other dry and porous substances, which may serve as manures for the fields destined to receive it.

Upon nearly all our farms the dung of quadrupeds is exposed to the open air, without the protection of a shed, as soon as it is removed from the stables; and is thus washed by the rains, which carry off all the salts, urine, and soluble juices, and form at the foot of the mass a rivulet of blackish fluid, which is either wholly evaporated or lost in the ground. In proportion as fermentation advances, new soluble combinations are formed, so that all the nutritive and stimulating principles of the dung gradually disappear, till there remain only some weak portions of the manure, intermingled with stalks of straw which have lost all their goodness.

To remedy as much as possible an abuse so injurious to agriculture, it is necessary at least to dig a deep ditch to receive all the juices which flow from the dunghill, in order that they may be used in the spring upon the corn or grass lands; or they may be preserved to water the grass lands with, after the first mowing. A large cask, fixed upon a small cart, and which can be filled by means of a hand pump, is sufficient for this purpose. Beneath the tap of the cask must be fitted a narrow chest about four feet long, with the bottom pierced with holes, through which the liquor may be scattered. This mode of watering, when used after mowing, produces wonderful effects upon the crop of the following year.

Before deciding upon the question, whether dung and litter should or should not be made to ferment, it is necessary to take into consideration the nature of the soil to be manured. If this be compact, clayey and cold, it is better that fermentation should not have taken place, as two effects will be produced by the application of the manure in an undecomposed state. In the first place it will improve the soil by softening and dividing it, so as to render it permeable by air and water; and in the next place it will, whilst undergoing the successive processes of fermentation and decomposition, warm the soil.* If, on the contrary, the soil be light, porous, calcareous, and warm, the thoroughly fermented manure or *short muck*, as it is called by farmers, is preferable, because it gives out less heat, and instead of opening the earth, already too porous, to the filtrations of water, it moderates the flow of that fluid. Long experience has made these truths known to observing, practical farmers.

When it is required to apply dung to any particular kind of soil, it is necessary that it should be used according to a knowledge of its qualities. The dung of animals bearing wool is the warmest; next, that of horses; whilst that of cows and oxen contains the least heat of any.

Soft or fluid animal substances change the most easily; and the progress of their decomposition is rapid in proportion to the diminution of the quantity of earthy salts contained in them. Their decomposition produces an abundance of ammonial gas. This circumstance distinguishes them from vegetable substances, the decomposition of which gives rise to the production of that gas, only as far as they contain a small portion of albumen. It is particularly to the development of ammonial gas, which, combined with gelatine, passes into plants, that we can attribute the wonderful effect produced upon vegetation by certain dry animal substances, of which we shall speak presently.

Next to the dung of animals, of which I have just spoken, the urine of horned cattle and of horses is the most abundant manure which can be used in agriculture; and it is not without regret that I see every day so little pains taken to collect it. I have already observed, that in those countries where agriculture is conducted with the most care and skill, all the stables are floored, and the bottoms of them gently sloping, so as to conduct all the urine into a reservoir, where the remains of rape seed, flax, wild cabbage, human excrements, &c. &c. are thrown into it to undergo fermentation. In the spring, when vegetation begins to be developed, this fermented liquor is carried into the fields to water the crops.

There are few animal substances of which the nature varies as much as that of urine; the quality of food, or the state of health, produces a sensible change in it.—The urine of animals is more or less abundant and active in its qualities, in proportion as their food is juicy or dry. Those which live upon dry fodder give less urine than those which are fed upon green herbage; but that of the first contains a greater quantity of salts than that of the last; and that which is produced directly by drink, contains less animal matter than that which is secreted from the blood by the urinary organs. There are different states of individuals, which may explain satisfactorily the disagreements in the results which have been given, by the numerous analyses which have been made of this fluid.

Mr. Brandt has found the urine of a cow to contain,

Water,	65
Phosphate of lime,	5
Muriate of potash and ammonia,	15
Sulphate of potash,	6
Carbonate of potash and of ammonia,	4
Urea,	5
	100

Messrs. Fourcroy and Vauquelin have extracted from that of the horse,

Carbonate of lime,	11
Carbonate of potash,	9
Benzoate of soda,	24
Muriate of potash,	9
Urea,	7
Water and mucilage,	940
	1,000

An analysis of human urine by M. Berzelius afforded,

Water,	933
Urea,	30.1
Uric acid,	1
Muriate of ammonia, free lactic acid, lactate of ammonia, and animal matter,	17.4
	981.5

The remainder is composed of sulphates, phosphates, and muriates.

It may be seen from these analyses, that there is a wide difference in the urine of various animals, but that all contain salts which enter into plants, with the water by which they are held in solution; and draw in at the same time those animal portions, which, like urea, are easily soluble, and can be decomposed without difficulty.

Amongst the principles contained in urine, there are some salts undecomposable by the digestive organs of vegetables; such are the phosphate of lime, the muriate and the sulphate of potash. These can serve only to excite and stimulate the organs; but the urea, the mucilage, the uric acid, and other animal matters, must be considered as eminently nutritive. Urine in its recent state should never be employed as manure; it acts with too much force, and has a tendency to dry the plants; it should therefore be either mixed with water, or allowed to ferment.

Urine is very useful for moistening all those substances which enter into compost; it increases the fertilizing properties of each one of them, and facilitates the fermentation of those which need to be decomposed before yielding their nutritive qualities.

Urine, when combined with plaister, lime, &c. forms a very active manure for cold lands.

Bones have, at the present time, become in the hands of the agriculturist a powerful agent in fertilizing the soil. These parts of animals are principally composed of phosphate of lime and of gelatine. Those bones which are most usually employed, contain about equal quantities of phosphate and gelatine. The bones of the ox yield from fifty to fifty-five per cent of gelatine; those of the horse from thirty-six to forty; and those of the hog from forty-eight to fifty.

The bones of young animals contain more gelatine than those of older animals, and have a less compact texture. The bones of the feet of the elk, the roe-buck, stag, and hare afford, upon analysis, from eighty to ninety per cent of phosphate.

When bones are to be employed as a manure, they should be ground fine, and thrown into a heap to ferment. As soon as this action shall have commenced, so as to give out a penetrating odor, the mass should be spread upon the earth, and be afterwards mixed with it; or it may be thrown upon the seed, and buried in the ground with it. When seeds are sown in furrows, it is a good method to place some of the ground bones in the furrows with them.

In some countries the fat and the greater part of the gelatine are extracted from bones, by boiling them in water, before selling them for agricultural purposes.—But by this operation they are deprived of a great part of their fertilizing powers. Upon carefully observing the appearance of a mass of bones under fermentation, I found the surface of a part of them to be covered with a thin coating of an unctous substance, sharp and biting to the taste. This appeared to me to be formed by the combination of gelatine with ammonia; this last being always developed during the decomposition of all animal substances. The observations of M. D' Arcet, to whom we are indebted for a very valuable work upon gelatine, support this opinion.

It is possible, that, when the ground bones are employed without having been first submitted to the commencement of a fermentation, the gelatine is gradually decomposed in the ground, and the same result at length produced; or, we can conceive that water, acting upon the bones, will dissolve the gelatine, and transmit it to plants; and in both these cases the influence of the bones upon vegetation is very great, whether it be considered as a purely nutritive manure, or in the double connexion of a nutritive and stimulating substance.

When bones are calcined in a close vessel, they yield oil and carbonate of ammonia; the proportion of the phosphate is not sensibly diminished; but the gelatine is decomposed. There remains after the operation from sixty-six to seventy-two per cent, of the weight of the bones employed. This residue, broken and pulverized with care, is of great use in the process of refining sugar. After having been used in this process, and become impregnated with ox blood and animal carbon, I have found it to be one of the best manures which I could employ for trefoil and clover. It should be scattered with the hand upon the plants, when vegetation begins to be developed in the spring.

Some of the dry parts of animals, as the horns, hoofs, and claws, approach closely to bones in the nature of their constituent principles; but the proportions of these vary prodigiously. In such parts, gelatine constitutes the largest portion; and for this reason they are more esteemed as manure than the bones. M. Merat-Guillot has found but twenty-seven per cent of phosphate of lime in the horn of a stag, and M. Hatchett, by an analysis of five hundred grains of the horn of an ox, gained only one-fifth part of earthy residuum, of which a little less than one half was phosphate of lime.

The clippings and parings of horns form an excellent manure, of which the effect is prolonged during a succession of years, owing to the difficulty with which water penetrates them, and the little tendency they have to ferment.

A very good manure is likewise formed from wool. According to the ingenious experiments of M. Hatchett, hair, feathers, and wool are only particular combinations of gelatine with a substance analagous to albumen; water can only dissolve them by means of fermentation, which takes place slowly, and after a long time.

One of the most surprising instances of fertile vegetation that I have ever seen, is that of a field in the neighborhood of Montpelier, belonging to a manufacturer of woollen blankets. The owner of this land causes it to be dressed every year with the sweepings of his work-shops; and the harvest of corn and fodder which it produces, are astonishing.

---

* A virtual admission, that the vegetable litter of the yards will undergo fermentation in a compact, clayey, cold soil; of course this process will the more readily take place on a porous, light and warm soil. Whence, then the economy of fermentation in the yard, at the expense of the volatile and more valuable parts of the manure? If fermentation will warm a cold soil, it will equally benefit a warm one, which we intend for our corn crop, and where the grand desideratum, in our northern climate, is to accelerate the growth and maturity of the crop.—*Cond.*

It is well known, that the hairs of wool transpire a fluid which hardens upon their surface, but which possesses the property of being easily soluble in water.—This substance has received the name of animal sweat; the water in which wool has been washed contains so much of it, as to make it very valuable as a manure.

I saw, thirty years since, a wool merchant in Montpelier, who had placed his wash-house for wool in the midst of a field, a great part of which he had transformed into a garden. In watering his vegetables, he had used no other water than that of the washings; and the beauty of his productions was so great, as to render his garden a place of general resort. The Genoese collect with care, in the south of France, all they can find of shreds and rags of woollen fabrics, to place at the foot of their olive trees.

According to the analysis of M. Vauquelin, this animal sweat is a soapy substance, consisting of a base of potash, with an excess of oily matter, and containing, besides, some acetate of potash, a little of carbonate and of the muriate of the same base, and a scented animal matter.

The dung of birds is another very valuble manure; differing from that of quadrupeds in the food's being better digested; in containing more animal matter, being richer in salts, and affording some of the principles which are found in the urine of four-footed animals.

The dung of those sea-fowls, which are so numerous in the islands of the Pacific ocean, and of which the excrement furnishes an important article of commerce with South America, as, according to the accounts of M. Humboldt, they import into Peru fifty shiploads of it annually, contains, besides a great quantity of uric acid partly saturated by ammonia and potash, some phosphate of lime, of ammonia and of potash, as well as some oily matter. Davy found the dung of a coromant to contain some uric acid.

The good effects resulting from the use of pigeons' dung, in our country, has caused it to be carefully collected. One hundred parts of this, when fresh, yielded to Davy twenty-five parts of matter soluble in water, whilst the same, after having undergone putrefaction, gave but eight; whence this able chemist concluded with reason, that it was necessary to employ it before being fermented. This is a warm manure, and may be scattered by the hand before covering the seed; or it may be used in the spring upon strong lands, when vegetation appears languid.

The excrement of the domestic fowl approaches nearly in its qualities to that of the pigeon, without, however, possessing the same degree of power. It contains also some uric acid, and may be applied to the same purposes as pigeons' dung.

In the south of France, where they raise many silkworms, they make great use of the larvas, after the silk has been spun from the cocoons. They are spread at the foot of the mulberry and other trees, of which the vegetation is in a languishing condition; and this small quantity of manure reanimates them surprisingly. Upon distilling some of these larvas, I found more ammonia than I have ever met with in any other animal matter.

Night soil forms an excellent manure; but farmers allow it to be wasted, because it is too active to be employed in its natural state, and they know not how either to moderate its action, or to appropriate it during different stages of fermentation to the wants of various kinds of plants.

In Belgium, which has been the cradle of enlightened agriculture, and where good modes of cultivation are continued and constantly improved, they make astonishing use of this kind of manure. The first year of its decomposition, they cultivate upon the soil to which it is applied, oleaginous plants, such as hemp and flax; and the second year sow the land with corn. They likewise mix water with urine, and use it to water the fields in spring when vegetation begins to unfold. This substance is likewise dried and scattered upon fields of cabbage.

The Flemings value this kind of manure so much, that the cities set a high rate upon the privilege of disposing of the cleansings of their privies; and there are, in each one of them, sworn officers for the assistance of those who wish to make purchases. These officers know the degree of fermentation suited to each kind of plant, and to the different periods of vegetation.

We shall find great difficulty in bringing this branch of industry to the same degree of perfection amongst us, that it has arrived at in Belgium, because our farmers do not realize its importance, and have a repugnance to employing this kind of manure. But could they not collect carefully all these matters, mix them with lime, plaster, or gravel, till the odor was dispelled, and then carry the whole upon the fields?

Already, in most of our great cities, the contents of the privies are used for forming *poudrette;* this pulverulent product is sought for by our agriculturists, who acknowledge its good effects; let us hope, that, becoming more enlightened, they will employ the fecal matter itself, as being more rich in nutritive principles, and abounding equally in salts; they can easily govern and moderate the too powerful action of this, by fermentation, or what is still better, by mixing with it plaster, earth, and other absorbents, to correct the odor.

As dunghills are the riches of the fields, a good agriculturist will neglect no means of forming them; it ought to be his first and daily care; for without dung there is no harvest. The scarcity of dunghills, or what is the same thing, the bad state of the crops, sufficiently proves the prejudices, by which the peasant is everywhere governed; and the habitual blindness with which he proceeds in his labors. In our country many of those who cultivate the land, know only the kinds of straw which are suitable for furnishing manure, and in a dunghill of litter, consider them as acting the principal part, whereas they are only feeble accessories.

According to the experiments of Davy, the straw of barley contains only two per cent of substance, soluble in water, and having a slight resemblance to mucilage; the remainder consists entirely of fibre, which can be decomposed only after a long time, and under circumstances calculated to facilitate the operation.

I do not believe that there is in the whole vegetable kingdom, an aliment affording so little nutriment, either for plants or animals, as the dry straw of grain: serving only to fill the stomachs of the latter; and furnishing to the former but about one hundredth part of its weight of soluble manure.

Weeds, leaves of trees, and all the succulent plants which grow so abundantly in ditches and waste lands, under hedges, and by the road side, if cut or pulled when in flower, and slightly fermented, furnish from twenty to twenty-five times more manure than straw does. These plants, carefully collected, furnish to the agriculturist an immense resource for enriching his lands. Besides the advantage arising from the manure furnished by these plants, the agriculturist will find his account in preventing the dissemination of their seeds, which, by propagating in the fields, deprive the crops of the nourishment of the soil. The turf, that borders fields and highways, may be made to answer the same purpose, by cutting it up with all the roots and the earth adhering to them, rotting the whole in a heap, and afterwards carrying the mass upon the fields, or what is still better, by burning it, and dressing the land with the products of the combustion.

If straw did not serve as beds for animals, and did not contribute, at the same time, to their health and cleanliness, it would be better to cut the ears of corn and leave the stalks in the fields; since they serve only as absorbents of the true manures.

It is always said that barn-yard manure, besides its nutritive virtues, possesses the advantage of softening hard lands, and rendering them permeable by air and water. I do not deny the truth of this; I even acknowledge that it owes this property almost entirely to the straw which it contains; but the same effect would be produced by burying the straw upon the spot.

[*Remainder in our next.*]

Young Men's Department.

Self-Culture.

BY W. E. CHANNING, D.D.

(*Concluded.*)

Among the best people, especially among the more religious, there are some, who, through disgust with the violence and frauds of parties, withdraw themselves from all political action. Such, I conceive, do wrong. God has placed them in the relations, and imposed on them the duties of citizens; and they are no more authorized to shrink from these duties than from those of sons, husbands, or fathers. They owe a great debt to their country, and must discharge it by giving support to what they deem the best men and the best measures. Nor let them say, that they can do nothing. Every good man, if faithful to his convictions, benefits his country. All parties are kept in check by the spirit of the better portion of people, whom they contain. Leaders are always compelled to ask what their party will bear, and to modify their measures, so as not to shock the men of principle within their ranks. A good man, not tamely subservient to the body with which he acts, but judging it impartially, criticising it freely, bearing testimony against its evils, and withholding his support from wrong, does good to those around him, and is cultivating generously his own mind.

I respectfully counsel those, whom I address, to take part in the politics of their country. These are the true discipline of a people, and do much for their education. I counsel you to labor for a clear understanding of the subjects which agitate the community, to make them your study, instead of wasting your leisure in vague, passionate talk about them. The time, thrown away by the mass of the people on the rumors of the day, might, if better spent, give them a good acquaintance with the constitution, laws, history and interests of their country, and thus establish them in those great principles by which particular measures are to be determined. In proportion as the people thus improve themselves, they will cease to be the tools of designing politicians. Their intelligence, not their passions and jealousies, will be addressed by those who seek their votes. They will exert, not a nominal, but a real influence on the government and the destinies of the country, and at the same time will forward their own growth in truth and virtue.

I ought not to quit this subject of politics, considered as a means of self-culture, without speaking of newspapers; because these form the chief reading of the bulk of the people. They are the literature of multitudes. Unhappily their importance is not understood; their bearing on the intellectual and moral cultivation of the community, little thought of. A newspaper ought to be conducted by one of our most gifted men, and its income should be such as to enable him to secure the contribution of men as gifted as himself. But we must take newspapers as they are; and a man, anxious for self-culture, may turn them to account, if he will select the best within his reach. He should exclude from his house such as are venomous or scurrilous, as he would a pestilence. He should be swayed in his choice, not merely by the ability with which a paper is conducted, but still more by its spirit, by its justice, fairness and steady adherence to great principles. Especially, if he would know the truth, let him hear both sides. Let him read the defence as well as the attack. Let him not give his ear to one party exclusively. We condemn ourselves, when we listen to reproaches thrown on an individual and turn away from his exculpation; and is it just to read continual, unsparing invective against large masses of men, and refuse them the opportunity of justifying themselves?

A new class of daily papers has sprung up in our country, sometimes called cent papers, and designed for circulation among those who cannot afford costlier publications. My interest in the working class induced me sometime ago to take one of these, and I was gratified to find it not wanting in useful matter. Two things however gave me pain. The advertising columns were devoted very much to patent medicines; and when I considered that a laboring man's whole fortune is his health I could not but lament, that so much was done to seduce him to the use of articles, more fitted, I fear, to undermine than to restore his constitution. I was also shocked by accounts of trials in the police court. These were written in a style adapted to the most uncultivated minds, and intended to turn into matters of sport the most painful and humiliating events of life. Were the newspapers of the rich to attempt to extract amusement from the vices and miseries of the poor, a cry would be raised against them, and very justly. But is it not something worse, that the poorer classes themselves should seek occasions of laughter and merriment in the degradation, the crimes, the woes, the punishments of their brethren, of those who are doomed to bear like themselves the heaviest burdens of life, and who have sunk under the temptations of poverty? Better go to the hospital, and laugh over the wounds and writhings of the sick or the ravings of the insane, than amuse ourselves with brutal excesses and infernal passions, which not only expose the criminal to the crushing penalties of human laws, but incur the displeasure of Heaven, and, if not repented of, will be followed by the fearful retribution of the life to come.

One important topic remains. That great means of self-improvement, Christianity, is yet untouched, and its greatness forbids me now to approach it. I will only say, that if you study Christianity in its original records and not in human creeds; if you consider its clear revelations of God, its life-giving promises of pardon and spiritual strength, its correspondence to man's reason, conscience and best affections, and its adaptation to his wants, sorrows, anxieties and fears; if you consider the strength of its proofs, the purity of its precepts, the divine greatness of the character of its author, and the immortality which it opens before us, you will feel yourselves bound to welcome it joyfully, gratefully, as affording aids and incitements to self-culture, which would vainly be sought in all other means.

I have thus presented a few of the means of self-culture. The topics, now discussed, will I hope suggest others to those who have honored me with their attention, and create an interest which will extend beyond the present hour. I owe it however to truth to make one remark. I wish to raise no unreasonable hopes. I must say then, that the means, now recommended to you, though they will richly reward every man of age who will faithfully use them, will yet not produce their full and happiest effect, except in cases where early education has prepared the mind for future improvement. They, whose childhood has been neglected, though they may make progress in future life, can hardly repair the loss of their first years; and I say this, that we may all be excited to save our children from this loss, that we may prepare them, to the extent of our power, for an effectual use of all the means of self-culture, which adult age may bring with it. With these views, I ask you to look with favor on the recent exertions of our legislature and of private citizens, in behalf of our public schools, the chief hope of our country. The legislature has of late appointed a board of education, with a secretary, who is to devote his whole time to the improvement of public schools. An individual more fitted to this responsible office, than the gentleman who now fills it,* cannot, I believe, be found in our community; and if his labors shall be crowned with success, he will earn a title to the gratitude of the good people of this State, unsurpassed by that of any other living citizen. Let me also recall to your minds a munificent individual,† who, by a generous donation, has encouraged the legislature to resolve on the establishment of one or more institutions called Normal Schools, the object of which is, to prepare accomplished teachers of youth, a work, on which the progress of education depends more than on any other measure. The efficient friends of education are the true benefactors of their country, and their names deserve to be handed down to that posterity, for whose highest wants they are generously providing.

There is another mode of advancing education in our whole country, to which I ask your particular attention. You are aware of the vast extent and value of the public lands of the union. By annual sales of these, large amounts of money are brought into the national treasury, which are applied to the current expenses of the government. For this application there is no need. In truth, the country has received detriment from the excess of its revenues. Now, I ask, why shall not the public lands be consecrated, (in whole or in part, as the case may require,) to the education of the people? This measure would secure at once what the country most needs, that is, able, accomplished, quickening teachers of the whole rising generation. The present poor remuneration of instructers is a dark omen, and the only real obstacle which the cause of education has to contend with. We need for our schools gifted men and women, worthy, by their intelligence and their moral power, to be entrusted with a nation's youth; and to gain these we must pay them liberally, as well as afford other proofs of the consideration in which we hold them. In the present state of the country, when so many paths of wealth and promotion are opened, superior men cannot be won to an office so responsible and laborious as that of teaching, without stronger inducements than are now offered, except in some of our large cities. The office of instructer ought to rank and be recompensed as one of the most honorable in society; and I see not how this is to be done, at least in our day, without appropriating to it the public domain. This is the people's property, and the only part of their property which is likely to be soon devoted to the support of a high order of institutions for public education. This object, interesting to all classes of society, has peculiar claims on those, whose means of improvement are restricted by narrow circumstances. The mass of the people should devote themselves to it as one man, should toil for it with one soul. Mechanics, Farmers, Laborers! Let the country echo with your united cry, "The Public Lands for Education." Send to the public councils men who will plead this cause with power. No party triumphs, no trades-unions, no associations, can so contribute to elevate you as the measure now proposed. Nothing but a higher education can raise you in influence and true dignity. The resources of the public domain, wisely applied for successive generations to the culture of society and of the individual, would create a new people, would awaken through this community intellectual and moral energies, such as the records of no country display, and as would command the respect and emulation of the civilized world. In this grand object, the working men of all parties, and in all divisions of the land, should join with an enthusiasm not to be withstood. They should separate it from all narrow and local strifes. They should not suffer it to be mixed up with the schemes of politicians. In it, they and their children have an infinite stake. May they be true to themselves, to posterity, to their country, to freedom, to the cause of mankind.

---

* Horace Mann.

† Edmund Dwight, Esq.

III. I am aware that the whole doctrine of this discourse will meet opposition. There are not a few who will say to me, "What you tell us sounds well; but it is impracticable. Men, who dream in their closets, spin beautiful theories; but actual life scatters them, as the wind snaps the cobweb. You would have all men to be cultivated; but necessity wills that most men shall work; and which of the two is likely to prevail? A weak sentimentality may shrink from the truth; still it *is* true, that most men were made, not for self-culture, but for toil."

I have put the objection into strong language, that we may all look it fairly in the face. For one I deny its validity. Reason as well as sentiment rises up against it. The presumption is certainly very strong, that the All-wise Father, who has given to every human being, reason and conscience and affection, intended that these should be unfolded; and it is hard to believe, that He, who, by conferring this nature on all men, has made all his children, has destined the great majority to wear out a life of drudgery and unimproving toil, for the benefit of a few. God cannot have made spiritual beings to be dwarfed. In the body we see no organs created to shrivel by disuse; much less are the powers of the soul given to be locked up in perpetual lethargy.

Perhaps it will be replied, that the purpose of the Creator is to be gathered, not from theory, but from facts; and that it is a plain fact, that the order and prosperity of society, which God must be supposed to intend, require from the multitude the action of their hand and not the improvement of their minds. I reply, that a social order, demanding the sacrifice of the mind, is very suspicious, that it cannot indeed be sanctioned by the Creator. Were I, on visiting a strange country, to see the vast majority of the people maimed, crippled, and bereft of sight, and were I told that social order required this mutilation, I should say, Perish this order. Who would not think his understanding as well as best feelings insulted, by hearing this spoken of as the intention of God. Nor ought we to look with less aversion on a social system, which can only be upheld by crippling and blinding the Minds of the people.

But to come nearer to the point. Are labor and self-culture irreconcilable to each other? In the first place, we have seen that a man in the midst of labor, may and ought to give himself to the most important improvements, that he may cultivate his sense of justice, his benevolence, and the desire of perfection. Toil is the school for these high principles; and we have here a strong presumption, that, in other respects, it does not necessarily blight the soul. Next we have seen, that the most fruitful sources of truth and wisdom are not books, precious as they are, but experience and observation; and these belong to all conditions. It is another important consideration, that almost all labor demands intellectual activity, and is best carried on by those who invigorate their minds; so that the two interests, toil and self-culture, are friends to each other. It is Mind, after all, which does the work of the world, so that the more there is of mind, the more work will be accomplished. A man, in proportion as he is intelligent, makes a given force accomplish a greater task, makes skill take the place of muscles, and with less labor, gives a better product. Make men intelligent and they become inventive. They find shorter processes. Their knowledge of nature helps them to turn its laws to account, to understand the substances on which they work, and to seize on useful hints, which experience continually furnishes. It is among workmen, that some of the most useful machines have been contrived. Spread education, and, as the history of this country shows, there will be no bounds to useful inventions.

But it is said, that any considerable education lifts men above their work, makes them look with disgust on their trades as mean and low, makes drudgery intolerable. I reply that a man becomes interested in labor, just in proportion as the mind works with the hands. An enlightened farmer, who understands agricultural chemistry, the laws of vegetation, the structure of plants, the properties of manures, the influences of climate, who looks intelligently on his work and brings his knowedge to bear on exigencies, is a much more cheerful as well as more dignified laborer, than the peasant, whose mind is akin to the clod on which he treads, and whose whole life is the same dull, unthinking, unimproving toil. But this is not all. Why is it, I ask, that we call manual labor low, that we associate with it the idea of meanness, and think that an intelligent people must scorn it? The great reason is, that, in most countries, so few intelligent people have been engaged in it. Once let cultivated men plough and dig and follow the commonest labors, and ploughing, digging and trades will cease to be mean. It is the man who determines the dignity of the occupation, not the occupation which measures the dignity of the man. Physicians and surgeons perform operations less cleanly than fall to the lot of most mechanics. I have seen a distinguished chemist covered with dust like a laborer. Still these men were not degraded. Their intelligence gave dignity to their work, and so our laborers, once educated, will give dignity to their toils.—Let me add, that I see little difference in point of dignity, between the various vocations of men. When I see a clerk, spending his days in adding figures, perhaps merely copying, or a teller of a bank counting money, or a merchant selling shoes and hides, I cannot see in these occupations greater respectableness than in making leather, shoes, or furniture. I do not see in them greater intellectual activity than in several trades. A man in the fields seems to have more chances of improvement in his work, than a man behind the counter, or a man driving the quill. It is the sign of a narrow mind, to imagine as many seem to do, that there is a repugnance between the plain, coarse exterior of a laborer and mental culture, especially the more refining culture. The laborer, under his dust and sweat, carries the grand elements of humanity, and he may put forth its highest powers. I doubt not, there is as genuine enthusiasm in the contemplation of nature and in the perusal of works of genius, under a homespun garb as under finery. We have heard of a distinguished author, who never wrote so well, as when he was full dressed for company. But profound thought and poetical inspiration have most generally visited men, when, from narrow cicumstances or negligent habits, the rent coat and shaggy face have made them quite unfit for polished saloons. A man may see truth, and may be thrilled with beauty, in one costume or dwelling as well as another; and he should respect himself the more for the hardships, under which his intellectual force has been developed.

But it will be asked, how can the laboring classes find time for self-culture. I answer, as I have already intimated, that an earnest purpose finds time or makes time. It seizes on spare moments, and turns larger fragments of leisure to golden account. A man, who follows his calling with industry and spirit, and uses his earnings economically, will always have some portion of the day at command; and it is astonishing, how fruitful of improvement a short season becomes, when eagerly seized and faithfully used. It has often been observed, that they, who have most time at their disposal, profit by it least. A single hour in the day, steadily given to the study of an interesting subject brings unexpected accumulations of knowledge. The improvements made by well disposed pupils, in many of our country schools, which are open but three months in the year, and in our Sunday schools, which are kept but one or two hours in the week, show what can be brought to pass by slender means. The affections, it is said sometimes crowd years into moments, and the intellect has something of the same power. Volumes have not only been read, but written, in flying journeys. I have known a man of vigorous intellect, who had enjoyed few advantages of early education, and whose mind was almost engrossed by the details of an extensive business, but who composed a book of much original thought, in steam-boats and on horseback, while visiting distant customers. The succession of the seasons gives to many of the working class opportunities for intellectual improvement. The winter brings leisure to the husbandman, and winter evenings to many laborers in the city. Above all, in Christian countries, the seventh day is released from toil. The seventh part of the year, no small portion of existence, may be given by almost every one to intellectual and moral culture. Why is it that Sunday is not made a more effectual means of improvement? Undoubtedly the seventh day is to have a religious character; but religion connects itself with all the great subjects of human thought, and leads to and aids the study of all. God is in nature. God is in history. Instruction in the works of the Creator, so as to reveal his perfection in their harmony, beneficence and grandeur; instruction in the histories of the church and the world, so as to show in all events his moral government, and to bring out the great moral lessons in which human life abounds; instruction in the lives of philanthropists, of saints, of men eminent for piety and virtue; all these branches of teaching enter into religion, and are appropriate to Sunday; and through these, a vast amount of knowledge may be given to the people. Sunday ought not to remain the dull and fruitless season, that it now is to multitudes. It may be clothed with a new interest and a new sanctity. It may give a new impulse to the nation's soul.—I have thus shown, that time may be found for improvement; and the fact is, that among our most improved people, a considerable part consists of persons, who pass the greatest portion of every day at the desk, in the counting room, or in some other sphere, chained to tasks which have very little tendency to expand the mind. In the progress of society with the increase of machinery, and with other aids which intelligence and philanthropy will multiply, we may expect that more and more time will be redeemed from manual labor, for intellectual and social occupations.

But some will say, "Be it granted that the working classes may find some leisure; should they not be allowed to spend it in relaxation? Is it not cruel, to summon them from toils of the hand to toils of the mind? They have earned pleasure by the day's toil and ought to partake it." Yes, let them have pleasure. Far be it from me to dry up the fountains, to blight the spots of verdure, where they refresh themselves after life's labors. But I maintain, that self-culture multiplies and increases their pleasures, that it creates new capacities of enjoyment, that it saves their leisure from being, what it too often is, dull and wearisome, that it saves them from rushing for excitement to indulgencies destructive to body and soul. It is one of the great benefits of self-improvement, that it raises a people above the gratifications of the brute, and gives them pleasures worthy of men. In consequence of the present intellectual culture of our country, imperfect as it is, a vast amount of enjoyment is communicated to men, women and children, of all conditions, by books, an enjoyment unknown to ruder times. At this moment, a number of gifted writers are employed in multiplying entertaining works. Walter Scott, a name conspicuous among the brightest of his day, poured out his inexhaustible mind in fictions, at once so sportive and thrilling, that they have taken their place among the delights of all civilized nations. How many millions have been chained to his pages! How many melancholy spirits has he steeped in forgetfulness of their cares and sorrows! What multitudes, wearied by their day's work, have owed some bright evening hours and balmier sleep to his magical creations! And not only do fictions give pleasure. In proportion as the mind is cultivated, it takes delight in history and biography, in descriptions of nature, in travels, in poetry, and even graver works. Is the laborer then defrauded of pleasure by improvement? There is another class of gratifications to which self-culture introduces the mass of the people. I refer to lectures, discussions, meetings of associations for benevolent and literary purposes, and to other like methods of passing the evening, which every year is multiplying among us. A popular address from an enlightened man, who has the tact to reach the minds of the people, is a high gratification, as well as a source of knowledge. The profound silence in our public halls, where these lectures are delivered to crowds, show that cultivation is no foe to enjoyment.—I have a strong hope, that by the progress of intelligence, taste, and morals among all portions of society, a class of public amusements will grow up among us, bearing some resemblance to the theatre, but purified from the gross evils which degrade our present stage, and which, I trust, will seal its ruin. Dramatic performances and recitations are means of bringing the mass of the people into a quicker sympathy with a writer of genius, to a profounder comprehension of his grand, beautiful, touching conceptions, than can be effected by the reading of the closet. No commentary throws such a light on a great poem or any impassioned work of literature, as the voice of a reader or speaker, who brings to the task a deep feeling of his author and rich and various powers of expression. A crowd, electrified by a sublime thought, or softened into a humanizing sorrow, under such a voice, partake a pleasure at once exquisite and refined; and I cannot but believe, that this and other amusements, at which the delicacy of woman and the purity of the christian can take no offence, are to grow up under a high social culture. Let me only add, that in proportion as culture spreads among a people, the cheapest and commonest of all pleasures, conversation, increases in delight. This, after all, is the great amusement of life, cheering us round our hearths, often cheering our work, stirring our hearts gently, acting on us like the balmy air or the bright light of heaven, so silently and continually, that we hardly think of its influence. This source of happiness is too often lost to men of all classes for want of knowledge, mental activity, and refinement of feeling; and do we defraud the laborer of his pleasure, by recommending to him improvements which will place the daily, hourly, blessings of conversation within his reach.

I have thus considered some of the common objections which start up when the culture of the mass of men is insisted on, as the great end of society. For myself, these objections seem worthy little notice. The doctrine is too shocking to need refutation, that the great majority of human beings, endowed as they are with rational and immortal powers, are placed on earth, simply to toil for their own animal subsistence, and to minister to the luxury and elevation of the few. It is monstrous, it approaches impiety, to suppose that God has placed insuperable barriers to the expansion of the free illimitable soul. True, there are obstructions in the way of improvement. But in this country, the chief obstructions lie, not in our lot, but in ourselves, not in outward hardships, but in our worldly and sensual propensities; and one proof of this is, that a true self culture is as little thought of on exchange as in the workship, as little among the prosperous as among those of narrower conditions. The path to perfection is difficult to men in every lot; there is no royal road for rich or poor. But difficulties are meant to rouse, not discourage. The human spirit is to grow strong by conflict. And how much has it already overcome! Uuder what burdens of oppression has it made its way for ages. What mountains of difficulty has it cleared! And with all this experience, shall we say, that the progress of the mass of men is to be despaired of, that the chains of bodily necessity are too strong and ponderous to be broken by the mind, that servile, unimproving drudgery is the unalterable condition of the multitude of the human race?

I conclude with recalling to you the happiest feature of our age, and that is, the progress of the mass of the people in intelligence, self-respect, and all the comforts of life. What a contrast does the present form with past times? Not many ages ago, the nation was the property of one man, and all its interests were staked in perpetual games of war, for no end but to build up his family, or to bring new territories under his yoke. Society was divided into two classes, the highborn and the vulgar, separated from one another by a great gulf, as impassable as that between the saved and the lost. The people had no significance as individuals, but formed a mass, a machine, to be wielded at pleasure by their lords. In war which was the great sport of the times, those brave knights, of whose prowess we hear, cased themselves and their horses in armour, so as to be almost invulnerable, whilst the common people on foot were left, without protection, to be hewn in pieces or trampled down by their betters. Who, that compares the condition of Europe a few ages ago, with the present state of the world, but must bless God for the change. The grand distinction of modern times is, the emerging of the people from brutal degradation, the gradual recognition of their rights, the gradual diffusion among them of the means of improvement and happiness, the creation of a new power in the state, the power of the people. And it is worthy remark, that this revolution is due in a great degree to religion, which, in the hands of the crafty and aspiring, had bowed the multitude to the dust, but which, in the fulness of time, began to fulfil its mission of freedom. It was religion, which, by teaching men their near relation to God, awakened in them the consciousness of their importance as individuals. It was the struggle for religious rights, which opened men's eyes to all their rights. It was resistance to religious usurpation, which led men to withstand political oppression. It was religious discussion, which roused the minds of all classes to free and vigorous thought. It was religion, which armed the martyr and patriot in England against arbitrary power, which braced the spirits of our fathers against the perils of the ocean and wilderness, and sent them to found here the freest and most equal state on earth.

Let us thank God for what has been gained. But let us not think every thing gained. Let the people feel that they have only started in the race. How much remains to be done? What a vast amount of ignorance, intemperance, coarseness, sensuality, may still be found in our community! What a vast amount of mind is palsied and lost! When we think, that every house might be cheered by intelligence, disinterestedness and refinement, and then remember, in how many houses the higher powers and affections of human nature are buried as in tombs, what a darkness gathers over society. And how few of us are moved by this moral desolation? How few understand, that to raise the depressed, by a wise culture, to the dignity of men, is the highest end of the social state? Shame on us, that the worth of a fellow creature is so little felt.

I would, that I could speak with an awakenig voice to the people, of their wants, their privileges, their responsibilities. I would say to them, you cannot, without guilt and disgrace, stop where you are. The past and the present call on you to advance. Let what you have gained be an impulse to something higher. Your nature is too great to be crushed. You were not created what you are, merely to toil, eat, drink and sleep, like the inferior animals. If you will, you can rise. No power in society, no hardship in your condition can depress you, keep you down, in knowledge, power, virtue, influence, but by your own consent. Do not be lulled to sleep by the flatteries which you hear, as if your participation in the national sovereignty made you equal to the noblest of your race. You have many and great deficiencies to be remedied: and the remedy lies, not in the ballot box, not in the exercise of your political powers, but in the faithful education of yourselves and your children. These truths you have often heard and slept over. Awake! Resolve earnestly on self-culture.—Make yourselves worthy of your free institutions, and strengthen and perpetuate them by your intelligence and your virtues.

Culture of the Mind.

Mind makes the man—
Want of it the fellow.

This motto, somewhat altered from Pope, has a peculiar bearing upon the agriculturist. The farmer possesses all the privileges, and most of the advantages, of other classes of the community; and if he will improve his mind, his influence will be as potent, and his example as salutary, as the influence and example of any other profession. The richest natural soil will produce neither bread nor meat without culture. The highest natural gifts of intellect will not profit the possessor, unless, like the rich soil, they are cultivated with assiduity and care. Good culture not only improves the mind, and fits it for high mental gratification and enjoyment, but it lightens the toils, and greatly increases the profits of labor. Franklin owed his fame, his fortune and his usefulness, to his early habits of study, of industry, and of virtue. Without these early habits, he probably would have risen to neither fame nor fortune. Some minds, like some soils, are naturally richer than others; yet even apparently sterile minds, like infertile soils, may, by good culture, be made to yield great returns. Let the young farmer, then, aspire to the highest honors of the nation, by endeavoring to improve his intellectual faculties; and if he does not attain the goal of his wishes, he may be sure of greatly improving his condition, and of benefitting others, provided always, that he is industrious and honest. However menial and servile agricultural labor may have been considered among the privileged classes of Europe; and however degrading it may yet be held by the would-be aristocracy of America, it has commanded the highest respects of good men in every age, and constituted, in our country, the favorite study and employment of a Washington, a Jefferson, a Madison, a Monroe, and a Jackson: of an Humphrey, a Livingston, a Shelby, an Armstrong, a Lowell, a Lincoln, and a great many others, whose names will stand out in bold relief upon the future annals of our country. Let, then, no young aspirant for fame and usefulness, shun rural employment, because it does not feed his hopes of distinction, and let no one, engaged in this employment forego the opportunity, which his condition presents, of cultivating his mind, as the surest means of sinking *the fellow*, and rising to the dignity of *the man*.

GREAT SALE of IMPROVED SHORT-HORN CATTLE AND BLOOD HORSES.—The subscribers will sell at auction, on *Tuesday the* 10*th day of September next*, at the farm of Samuel Allen, on the Niagara river, two miles below Black-Rock, the entire stock of Imported Short-Horn Cattle, for several years past bred on the farm of L. F. Allen, on Grand-Island.

The herd consists of about thirty, including Cows, Bulls, Heifers and Calves. Several of them have been imported by one of the subscribers, direct from England, and with their produce, are surpassed by few animals in the country. In addition to these, every animal offered is the direct descendant of thorough bred imported stock, and of unquestionable purity of blood.

With the above will be sold twenty select and beautiful animals, consisting of pure Devon; crosses of different degrees between the Devon and Improved Short-Horns; crosses of the Alderney and Ayreshire with the Short-Horns. These are Cows, Heifers and Calves, all superior animals.

ALSO—The superb horse "BELL-FOUNDER," got by imported Bellfounder, the best thorough-bred trotting horse ever in America, and out of the imported mare Lady Allport, bred by T. T. Kissam, Esq. of Long-Island. The stock of this horse is unsurpassed in the country for size, speed and action—together with several elegant, thorough-bred breeding mares and fillies, and two or three young horse colts, the produce of the above. These animals are of the highest character as roadsters, and as trotters, no blood in the country has excelled them. They are all from the best stables of Long-Island. Also, a beautiful pair of full-bred matched fillies, five years old. All these horses are blood bay.

This entire stock will be sold without reserve, to the highest bidder, commencing at 10 o'clock A. M. They can be shipped within an hour from the farm, on board the steamboats to go up the Lakes, or on board canal boats at the farm.

Catalogues of the animals, with descriptions and pedigrees, will be prepared, and the stock may be viewed at the farm previous to the sale. A credit of sixty days will be given on approved notes or acceptances, payable at a bank either in Buffalo, Albany, or New-York, for all sums over $300.

LEWIS F. ALLEN,
SAMUEL ALLEN.

Black-Rock, N. Y. June 25, 1839.

The "Ohio Farmer" and "Lexington (Ky.) Intelligencer," will please insert the above till first September, and send their bills to the subscribers for payment. ts.

☞ **A FEW COPIES** of the published volumes of the "FARMER'S CABINET," bound in boards, published at Philadelphia, have been received, and are for sale at the Cultivator office. A subscription has also been received for the "BOSTON CULTIVATOR." Subscriptions are also received for any and all of the agricultural publications published in the United States.

We repeat the remark, that no one periodical can, or does contain, all that it is interesting for the farmer to know, in order to improve his business; and that we shall very cheerfully lend our aid, free of charge, to furnish any gentleman, or association, with such agricultural periodicals as they may desire. Our professed object being the promotion of agricultural improvement, the conductors of agricultural journals are persuaded, that the harvest will be in proportion to the seed sown. August, 1839. tf

IMPROVED DURHAM SHORT-HORNS.—Mr. WHITAKER'S third sale of high bred improved Short-Horns, by the ship Napier, will be held at Powelton, near Philadelphia, on Friday the 20th September, 1839, at 10 o'clock A. M.

The subscriber is authorised by Col. Powell to say, that all the best cattle which he has at any time imported, and the improved short-horns which he considered the best in England, were either in Mr. Whitaker's possession, or were derived from his fold. Col. Powell has not the slightest interest in Mr. Whitaker's sales. Philadelphia, July 15, 1839.

ts C. J. WOOLBERT, *Auctioneer.*

NEW-YORK URATE AND POUDRETTE COMPANY, not incorporated, but carried on by individual enterprise. The manures are not divided among the stockholders, as are those belonging to another establishment, but sold to applicants for cash on delivery. Orders are supplied in the order of time in which they are received. Urate 50 cents and Poudrette 40 cents per bushel, with contingent charges for bags or barrels, &c.

The company are daily preparing for use, during the warm dry weather, the materials collected during the past winter, and will have several thousand bushels ready before the first of October next. The material is disinfected and rendered free from offensive smell by a compound, every part of which is in itself a good manure. The experience of the past and present year, 1838 and 1839, on Long Island, has satisfied many of the farmers that these manures have the quickest operation upon vegetable matter, producing greater abundance, and the cheapest of any manure they have ever tried.

Amended instructions for their use, the result of practical experience, will be furnished on application. The effect of Poudrette upon grape vines and morus multicaulis is beyond all comparison. This company are erecting large and extensive works in the vicinity of the city of New-York to prepare the manures; and farmers and gardeners may confidently rely on a supply. Orders, post paid, directed to "The New-York Urate and Poudrette Company," box number 1,-211, post-office, New-York, or sent to the store of STILLWELL & DEY, number 365, Fulton-street, Brooklyn, will be attended to. *New-York, July* 17, 1839.

The company will be very much obliged to gentlemen who have used the manures, to give them a statement in writing what has been the result of their use and experiments in relation to them. aug–4t.

WATKINS' PATENT WHEAT FANS, GRAIN CRADLES, and every other variety of tool required for harvesting, for sale by R. SINCLAIR & Co.
July–2t Baltimore, Md.

AGRICULTURAL WAREHOUSE and SEED STORE, 79 Barclay-street, New-York. At this old established stand, the subscribers take pleasure in announcing to the public, that they have made extensive arrangements to accommodate farmers in all articles connected with husbandry, viz:—Agricultural implements, a full and fresh supply of Field and Garden Seeds, Fruit Trees, Durham Cattle, Chinese and Berkshire pigs, 10,000 morus multicaulis mulberry trees, publications on rural subjects, &c.

Published here, the Rural Library, S. Fleet, editor; a few copies of 1st vol. for sale. The object of this work is to constitute a library at the least possible expense. 2d vol. commencing with Prof. Low's Elements of Practical Agriculture, with nearly 250 fine engravings; subscription $3. Subscriptions received for the Genesee Farmer, Cultivator, &c.

July–3t J. W. WEAVER & Co. 79 Barclay-st. N.Y.

FOR SALE—A splendid Farm, in the town of Hillsdale, Columbia county, N. Y. situated 18 miles east of the city of Hudson, containing about 208 acres of first rate land, about 180 of which is fine level arable soil, of an excellent quality, in a good state of cultivation, and on a very public road from New-York to Albany, and not surpassed by any in Columbia, for fertility; the remainder in fine timber; about 30 acres of good pine and chestnut timber. This situation is the most splended in the town of Hillsdale. The farm can conveniently be divided in to two farms, giving an equal quantity of timber land to each. There is a beautiful grove of fruit and ornamental trees about the main dwelling; also three other DWELLING-HOUSES, three Barns, besides Hay Barns and Barracks, Sheds, &c. Also, out-houses of almost every description, and in first rate order.

Also—Several lots of land in the counties of Broome and Tioga. Terms of payment made to suit the purchaser. Inquire of the subscriber on the premises.

July–2t BARENT WAGER, Hillsdale.

FOR SALE—A Splendid Country Seat in the Highlands, on the Hudson River. That beautiful country residence, known by the name of the BEVERLY ESTATE, containing four hundred acres of land, about two hundred of which are fine level arable soil, of an excellent quality, in a good state of cultivation, and not surpassed by any on the river for fertility; the remainder is fine and thrifty timber land. The situation is the most eligible on the Hudson, extending one mile and a half on the river, with a bold shore and convenient dock, nearly opposite West-Point, and within fifty miles of New-York. The prospect is extensive and diversified, reaching from St. Anthony's Peak on the south, to the bay and city of Newburgh on the north. This estate can conveniently be divided into three farms, giving an equal proportion of front on the river, and of arable and timber land to each. Almost every enclosure is supplied with living springs of the purest water. There is on said estate a plain house, (formerly the head-quarters of Gen. Arnold;) also out-houses necessary to carry on the business of the farm. The single fact that during the whole time the cholera raged throughout the state, not one case occurred within ten miles of this place, is sufficient to prove the unrivalled salubrity of the situation. The facilities of intercourse with the city, that can be reached in four hours, by means of numerous steam-boats, are great, and daily increasing, both as regards pleasure, and the convenience of a near market for produce of every description.

For conditions of sale, apply to STEPHEN A. HALSEY, 189 Water-street, New-York, or RICHARD D. ARDEN, on the adjoining farm. Ardenia, 23d April, 1839. j6t

FROM THE STEAM PRESS OF
PACKARD, VAN BENTHUYSEN & Co.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. AUGUST 15, 1839. No. 7.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—Lewis Hill & Co. Richmond, Va.; Bell & Entwistle, Alexandria, D. C.; Gideon B. Smith, Baltimore, Md.; Judah Dobson, bookseller, D. Landreith, and M. S. Powell, seedsmen, Philadelphia; Israel Post, bookseller, 88 Bowery, Alex. Smith, seedsman, P. Wakeman, office of the American Institute, Broadway, New-York; Hovey & Co. Merchants' Row, Boston; Alex. Walsh, Lansingburgh, and Wm. Thorburn, Albany, gratuitous agents; John Thorburn, seedsman and general agent, St. Louis, Mo. For general list of agents, see No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

The Crops in the West,

Our correspondent at Black-Rock, writes, July 20:—"The crops all, save grass, which is tolerable, are enormous in this region. The world never saw, before, such crops in Western New-York, Ohio, and the great west, in the way of wheat, as this year. It will not exceed seventy-five cents a bushel west of this, if it is so much; possibly not over fifty to sixty cents. The millers will learn caution from their great temerity and losses, and the farmers, hundreds of whom are now lamenting over the last crop, for which they had refused high prices, will learn to take a good price when offered hereafter."

Mr. Colman's Agricultural Report.

There are some items in this report which we go back to notice; and,

1. "*The manufacture of Charcoal.*—The growth of Mount Washington is principally white birch and chesnut, with some maple and oak. A great business of the inhabitants on the mountain, and of many persons in the neighborhood, is the conversion of this wood into coal, of which 100,000 bushels are stated to be annually made. Two and a half cords of wood are required to make 100 bushels of coal. By good management, two cords will make 100 bushels. The wood standing is valued at from 50 to 75 cents per cord. A kiln of common size contains from 25 to 30 cords. The chopping of two cords for the kiln, is considered a good day's work for a man. Collecting and drawing together on good ground, requires five days. The covering of a kiln requires three days' work. The burning of a kiln is twelve days' work. The coal brings 12½ to 13 cents at Hudson, about 24 miles distance, or 5½ to 6½ at Riga ironworks."

We introduce this extract, for the purpose of suggesting some facts which may benefit both the burner and the buyer of charcoal, which has come to be an article of great consumption in our towns and villages. We have extensive ranges of mountains on the east, in Rensselaer, and on the west, in Schoharie, covered with wood, but too remote from navigable waters, and from large towns, to admit of the fuel being carried to market, except in the form of charcoal. When economically managed, this article is made a source of profit, although the transportation to market may be 20 or 30 miles. A farmer in Schoharie, living 28 miles from the city, informed us, that in seven years he has paid for a new farm, got a large portion of it under good improvement, and built comfortable buildings, almost exclusively from charcoal which he has himself made and marketed from wood growing upon it.

The interests of both the buyer and seller, require that charcoal be properly burnt. Of the seller, because, if properly managed, he gets a third more coal than when the burning process is badly managed, and has a more ready market. Of the buyer, because he gets a far better article. The value of charcoal is determined by its specific weight. A hundred *pounds* of pine charcoal is worth as much to the consumer as a hundred *pounds* of hickory or maple charcoal, though the former may exceed the latter in volume one-half. It is *weight,* not *bulk,* that determines its intrinsic value.—Hence it would be a wise municipal regulation to regard the standard of value by weight, taking care that the wood is thoroughly charred.

To obtain the largest quantity, and best quality of coal, it is necessary to exclude the air from the pit, while in the process of burning. The quality and quantity will depend upon this exclusion. If burnt without any covering, there would be little or no charcoal, and that little would be inferior. Hence it is essential, that not only the coal pit be well covered, and be kept well covered, but that the interstices between the wood be filled with some substance that will exclude the air, without retarding the burning process. Dr. Bull, whose excellent experiments and remarks upon this subject we cannot now lay our hands upon, directs, that these interstices be filled, as the wood is fitted in the pit, with the coal dust of former pits, a work of no great labor; and that this will not only give more coal, but better coal. Coal burnt in this mode will have a solid and brassy surface, a sonorous sound, and comparatively great specific weight—criteria which the buyer should especially look for. Charcoal badly burnt, will, on the contrary, exhibit a crumbly soft surface, a dark color, and be comparatively light.

2. *Marble quarries.*—Upon the eastern border of Berkshire, we meet with that extensive marble formation, which extends, in a direction nearly north and south, from Long-Island Sound to the northern boundary of Vermont, at Swanton; and the quarries of Sheffield, West-Stockbridge, Hancock, &c. are extensively worked. The marble for the Girard College, at Philadelphia, is obtained from the first named town; and blocks weighing from seven to thirteen tons, have been transported across to Hudson, 24 to 26 miles, by oxen and horse teams.

3. *The agricultural capacities of Berkshire* are great. With a district highly congenial to the rearing of cattle, and the extension of the dairy; within a short distance of navigable waters, and great facilities for transportation to market; and a soil highly favorable to root crops and coarse grains, on which to fatten them, the agriculture of Berkshire admits of great improvement.—The more cattle, the more manure; and the more manure, the higher may be the condition of the land, and the greater the return in arable crops.

4. *Domestic Economy.*—"In looking over my returns," says the commissioner, "I was struck with the remarks of a man of much practical wisdom, and one of the best farmers of the commonwealth. He says, 'that a farmer should produce upon his farm, all those supplies for his family, which the farm can be made to yield.'"

This is true in regard both to the individual farmer, and a nation of farmers. The more either subsist upon the products of their own labor, the more independent they are, and generally the more prosperous too. Mr. Colman remarks upon this good rule of olden times:—

"In his case this is done, within doors and without; for there the spinning-wheel has not forgotten to turn round, nor the shuttle to speed its flight. In this *cottage,* [we suppose the commissioner means *farm-house,*] whose neat and beautiful arrangements cannot be surpassed, the clothing, the bedding and the carpeting, were all the product of their own fields and flocks. I shall not soon forget the unpretending and hearty hospitality of these enviable dwellings. I have slept many a time under a silken canopy, and trodden many a carpet as soft as the pride of eastern luxury could make it; but never with any thing like the sentiment of honest pride and independence with which I saw here the floors spread with carpets made from their flocks, which for fineness and beauty the foot of a princess need not disdain; and on a cold night slept in woollen sheets from their looms, as soft as the shawls of Cashmere, [rather high colouring;] and wiped my face with towels spun with their own hands, from their own flax, of a whiteness as transparent as the drifted snow. In such beautiful examples of domestic management, it is delightful to see with how limited means the best comforts and luxuries of life may be purchased. Nor were these instances few. The county of Berkshire abounds with examples of this domestic comfort and independence. Much to be regretted will be the change, which has already invaded many parts of the state, where, under the pretence of superior cheapness, these household fabrics shall give place to the more showy but flimsey products of foreign industry; and the healthy exercise of domestic labor and household cares shall be deemed degrading in our wives and daughters, and exchanged for the idleness and frivolities of pride and luxury."

5. *Composts and Liquid Manures.*—The commissioner urges increased attention to manures, as "the very sinews of agriculture; its food; its life-blood." He recommends that manures be mixed with earths, in the form of composts, in order to preserve their gaseous and liquid properties. In this way, he says, the amount of manure is greatly increased.

The subject of composts is one of calculation. If manure ferments in the yard, or upon the surface, a great portion of its fertilizing materials are undoubtedly wasted. It is no less true, that if the fermentation takes place while the dung is in a commingled state, with earthy matters, that the earths will absorb, in a measure, the gaseous and liquid portions of the manure, and hold them, and when applied to the land, give them off to the growing crops. Judge Hecock, a former professor of agriculture, contends, that these composts should be in the soil of the field where the manures are to operate. That by this mode, the expense of carting the earth to the yard, and afterwards to the field is saved. Mr. Colnan thinks they should be formed in the yard. Our opinion coincides with Judge Hecock's. We can have no more of the cat than her skin. The earths can only gain what the dung loses; and if the change takes place in the soil, the double expense of transportation is saved.

We contend, that all the dung of the stable and cattle yards should be applied, in spring, to hoed crops. If it has been spread over properly constructed yards, which retain the liquids, and the yard littered with the refuse vegetable matters of the farm, no hurtful fermentation will ensue before the dung is wanted for the hoed crops. But will this dung rot in the soil, it will be asked, in time to give food to the growing crop? We answer, yes. There is not a question that green vegetable manure undergoes a speedy decomposition when buried in the soil; and it is almost as apparent, that vegeto-animal manures, a term which Chaptal properly applies to the dung of animals which feed upon hay and like forage, will almost as speedily decompose under like circumstances, if saturated with the liquids of the yard, or other moisture, when buried. Judge Hecock made an experiment with dry straw. He buried it in a trench, and after covering it with earth, he planted melons, and had an uncommon fine crop. In the autumn, the straw was found to be perfectly rotted. We repeated his experiment, and with a like result. We have hardly a doubt, that where long manure is applied broadcast, and buried with the plough, it will rot, and feed the crop growing on it; and if not so efficient in the early part of the season, it will be more efficient towards the latter part than fermented dung. We manured a field of corn, part with manure which had been drawn out in the winter, and had undergone a partial fermentation, and part with coarse unfermented manure from the cattle yard, upon which fermentation had hardly commenced. The old manure gave the earliest growth, but the new manure gave the strongest after-growth, and at least one-fifth the greatest product in corn. Hence we consider all composts, made with manure which can be applied in a fresh state to hoed crops, as involving a useless expense of labor, without any corresponding return.

Where manure is drawn to the field sometime before it is to be used, or where it is not wanted for the spring crop, Mr. Colman's recommendation of mixing it with earth, or at least of covering it with earth, is undoubtedly proper. Again—where it is desirable to bring insoluble matter, as peat earth, into an available condition for crops—and where this cannot be sufficiently done by bedding the cattle yards with it, its admixture with unfermented manures, in the form of a compost, may be highly proper.

With regard to liquid manure, we have hardly yet begun to learn its value. The commissioner recommends the construction of water-proof vaults, or cisterns, under or contiguous to cow-houses. We have added contiguous, for we should prefer the outside rather than inside of the building, for the convenience of pumping the liquid into carts, when wanted, and for the greater convenience of conducting to it, from all the stables and sheds, the urine of the animals which they shelter. We do not like the suggestion, however, of housing cows during the summer months, with the view of saving their urine. It will be saved in the yard, if this is made concave, and kept well littered. Cows do not do so well in confined stables, nor so well tied, at a season when they are tormented with flies. "Doubling our manures," says the commissioner, "is quadrupling our crops."

Under the head of *Machinery,* Mr. Colman notices the Drill-barrows of Mr. Bushnell, of Sheffield, and of Mr. Metcalf, of Lenox; a Thrashing Machine made in Hinsdale, N. Y. and the smoke-house of Mr. Spicer, which has two apartments, one for the fire, and the other for the meat which is to be smoked.

In regard to smoking meat, our common mode is a bad one. We half cook it, as well as smoke it. The Dutch, and no people have better smoked meats, make their smoke in the cellar, and apply it to the meat in the garret. We do not want heat, but merely smoke, or the pyrolignic acid which the smoke contains, to dry and cure our meats. The desideratum, therefore, should be, to obtain the smoke without the heat, and this can only be well affected by employing separate apartments for the fire and the meat, and by conducting the smoke to the latter by artificial means.

Water-Works.—This is a contrivance, on the farm of Mr. Bassett, of Lee, for forcing up the water from a brook to the barn, similar, we presume, to one constructed at our neighbor's C. N. Bement. A three-foot head of water is raised in a small stream, which serves to turn a wheel, which carries a horizontal pump, and which latter forces the water, through pipes connected with it, up a hill of some sixty feet elevation, and discharges it into a tank.

There is subjoined to Mr. Colman's report, an appendix, containing several matters of interest, which we have not now sufficient room to notice. Among other things is an experiment, on two trials proving successful, of A. C. Metcalf, of Lenox, for preventing the ravages of the *Borer* on the locust tree.

The remedy is simply to wash the bole of the tree, in the early part of the summer, with spirits of turpentine. The trees soon lost the sickly appearance occasioned by the borer, assumed a healthy hue, and afterwards did well. Mr. M. thinks, that on a large scale, the spirits of turpentine would prove equally efficient if diluted with muddy water, as it will not mix with that which is pure.

The cedar owes its exemption from insects and from decay, to its resinous properties, which are obnoxious to the insect tribes, and which exclude moisture. It is stated, that cedar has been recently dug out of the ground, on the site of ancient Utica, which must have been buried more than two thousand years, in a sound condition.

The English Agricultural Society,

Has just held its first anniversary meeting; and so far as we are enabled to judge from their labors thus far, the society is likely to prove of immense advantage to the nation. It appears from the first annual report, that there are already 1104 members of different classes; that its subscriptions amount to about $36,000; that ten prizes have already been awarded for prize essays to be read before the society; that an extensive correspondence has been opened with the agricultural, horticultural, entomological and statistical societies of Europe; that geological collections are being made, and the basis of a library laid; that the first number of a journal, containing their proceedings and prize essays was commenced in April last, &c. The report concludes with a list of prizes to be awarded, amounting to some thousand dollars, and of the prominent objects which are primarily to engage the attention of the society. Of the latter, the following are the heads:

1. Classification of soils.
2. Permanent improvement of soils.
3. Productiveness of seeds.
4. Manures.
5. Rotation of crops.
6. Stock.
7. Mechanics of agriculture.
8. Diseases of cattle and plants.
9. Grass farms.
10. Physiology of agriculture.

We note these heads as constituting the great points of improvement in the agriculture of every country, and particularly in the agriculture of the United States, and as calculated to produce, in the investigations to which they will lead, the highest advantages to civilized society. And we repeat the remark, in a hope of stimulating to the organization of a like society in our country, upon a liberal and enlightened scale, that the English Agricultural Society embraces men of the highest standing in the kingdom, in reference to rank, influence and science. With us, unfortunately, our great men are too much engaged in politics, in commerce, or in speculation, and either do not appreciate justly the importance of agricultural improvement, or have not leisure or patriotism to bestow proper attention upon it.

The Great Principles of Agriculture

Are the same every where. Animal and vegetable matters constitute every where the food of plants; and heat, moisture and atmospheric air, universally, the active agents of vegetable nutrition. With a knowledge of the truth of these great principles, it is the province of man to apply them, under the various contingencies of climate, soil, aspect and seasons. And this is a labor in which the mind, enlightened by science, and fortified in its conclusions by experience, can do far more than the hands. The cultivated mind, like steam-power, is a labor-saving principle, capable of performing, or of saving, an immense amount of labor.

The efficacy of Green Crops as Manure.

We do not remember to have seen a more successful experiment made with green crops as a manure, or a stronger proof of their great value, than was made by John Kelly, of Essex, Mass. and communicated by him to the agricultural society of that county. The experiment was made upon a sandy plain. The customary crops were from eight to thirteen bushels of rye, and from thirteen to thirty bushels of Indian corn per acre. Grass would not grow upon it. The green crop was charlock, or wild mustard, which sprung up spontaneously, and was ploughed under three times successively as it came into bloom. The land had been the three preceding years in corn, enough to exhaust good land. The charlock was ploughed under the 18th of June, the 7th of August, and the 14th of September; the seed was sown immediately upon the last furrow, as the ploughing progressed, and harrowed in. The piece contained one acre and thirteen rods, and yielded *forty-three bushels and three pecks.*

Mr. Kelly did not think the experiment *quite complete.*

"To render it more so," he says, "I would not turn a furrow after the dew had evaporated. I have no doubt but a large portion of that fertilizing quality in the soil, which, (during the summer months,) is continually exhaled from the earth, is by the dew brought again within our reach, and it would be wise to avail ourselves of the opportunity of laying it again in the soil. And in the second place, I would by all means use a heavy roller after each ploughing. It would fill all the crevices left by the plough, and by pressing the soil more closely to the weeds, at once hasten the decomposition, and very much retard the evaporation from the soil.

"But the land is not only very much enriched by the process. There is, I conceive, no method by which it can be so thoroughly cleaned. Three times during the season, a fresh surface is presented to the atmosphere, and each time, as the decaying vegetable matter increases in the soil, so is the exciting cause augmented to make a more vigorous effort. We have in this manner gone over nearly all our land which is infested with charlock, and the diminution of the weeds is quite sufficient to warrant the expectation, that in a few years it may be comparatively eradicated."

This is scientific practice—the reasoning of a rural philosopher—a cheap and sure means of cleaning and imparting fertility to an exhausted or poor soil. In regard to the utility of ploughing in the dew, we have been told of a case in point, which took place some years ago, in Pittsfield. A poor laboring man asked permission to crop a piece of ground belonging to a wealthy neighbor, which had been thrown into *old field,* as not worth cultivation. Permission was granted. As the applicant worked out upon hire, and could not lose his time, he contrived to do all the ploughing after sundown, and before sun-rise. His crop was a very fine one; and the fine product was attributed to the circumstance of the ploughing having all been done while the dew was upon the surface. These lessons should not be lost upon the reader.

The Circumscribed Farmer,

We mean such as possess a limited capital, and limited desire for improvement, except in their own way, often decline taking an agricultural paper, because it teaches nothing, they say, that is adapted to their practice, or that is graduated to their scale—because, in fact, it is not oral, and delivered by word of mouth, but has been subjected to the operation of the printing press.

Let us ask these gentlemen, if they were disposed to have their son learn a trade, or to become a first rate farmer, would they select a teacher of circumscribed knowledge, who followed the practices of the last century, or knew only how to *kill land*—or one who was familiar with all the improvements of the age, and whose thrift in business would be a guarantee that he *worked* it right? Now the agricultural journal is to the circumscribed farmer, what the good teacher would be to the boy—an instructor in the improvements and best practices in his business—written by those who have made and adopted them, and have profited by them,—and for the particular benefit of those who have limited means, or cannot go abroad for the information they need. The modern improvements in farming go to economize labor, or rather to render labor more productive and profitable, and to keep up the fertility of the soil—two objects of as much or of more importance to the circumscribed farmer, than it is to the one of more extended means. The man who takes an agricultural journal profits by the experience of hundreds; while he who takes none, can profit alone from his own, and from that of perhaps a few neighbors. The adage teaches, that two heads are better than one, the world over.

These remarks are preliminary to some extracts we are about to make from John Lorain, a philosopher and a first rate farmer, written for the special instruction of circumscribed farmers, to whose notice they are respectfully recommended.

"In this country, land is very cheap: an excellent ready cash market for the produce of the soil generally prevails. This offers every rational encouragement to the poor but industrious farmer, who depends principally on his own labor, and that of his family, for cultivating the soil occupied by him. He is but little affected by the high price of labor, or the idleness and insolence of workmen, which take place in every country where labor is scarce, unless the laws be oppressively severe.

"The principal reason why this class of farmers so seldom become wealthy, and but too frequently continue poor, is the desire of immediate returns from cropping, and the mistaken idea that the profits to be derived from rearing live stock, progress too slowly to answer their purposes. This induces them to crop the soil yearly, with but little attention to grass or an increase of cattle, until their grounds become so much exhausted that rest is absolutely necessary to procure crops worth gathering. The soil being greatly impoverished, and the seeds of the grasses destroyed, as far as perpetual ploughing and cropping can effect this ruinous purpose, the grounds rest with no other covering, but that of some scattering and debilitated grass and weeds. This exposes the soil to the very injurious action of the sun, wind, washing rains and melting snows. When such grounds are ploughed for crops, instead of being richly stored with grass roots, and well covered by their tops, scarcely any vegetation is found to replenish them, or to nourish the crops grown on them.

"These ruinous practices naturally introduce poverty of soil, and its inseparable companion, poverty of purse. This, however, is not all; it entails on posterity the wretchedness introduced by their inconsiderate forefathers, or an Herculean task to counteract the curse of poverty, which their negligence had introduced. Whether Satan is also the instigator of this evil, I do not presume to determine, but certain I am, that it is much greater, (so far as farming be concerned,) than the curse entailed on the soil by the fall of Adam. That seems to consist simply in brambles and thorns, including in these, such other vegetation as would compel man to earn his bread by the sweat of his brow. This curse we may all see is irrevocable, but we may also, at the same time observe, that if man complies with heaven's mild decree, and removes those obstacles to the growth of plants, which better suit his purpose, agriculture flourishes, and his rational wants are abundantly supplied.

"But when the hand of folly introduces the additional curse of poverty on the soil, this insatiable monster, like Aaron's serpent, swallows all the rest. Even brambles, thorns, &c. (the mild chastisement of heaven,) cannot prosper where poverty has obtained dominion over the soil, as may be readily seen, for this and every other vegetation grown on such grounds, looks sallow, starved and debilitated.

"That man is inexcusable, and ought to be punished for this sin against common sense, himself, his posterity, and the community in which he resides, is evident.

"Before this inconsiderate being enters the forest, glade or prairie, nature had been for ages enriching the soil for his use, in the way that has been described. The fertility of it might be preserved and increased, even by the circumscribed farmer, if a system of agriculture calculated to keep the ground fully replenished with decaying animal and vegetable matter was practised, and due attention were paid to the augmentation of live stock, in proportion to an increase of ability, instead of the ruinous practice of perpetual ploughing and cropping.

"Reason, alone, demonstrates this interesting fact. It has also been clearly proved by actual practice, in almost every neighborhood, by the successful enterprise of farmers, who commenced their business on lands bought on credit, and covered with timber, without any buildings on them, and with not more than a pair of working cattle, and cows barely sufficient to supply the family with butter and milk. Nay, more—some who were not half as well stocked as this, have paid for their land, acquired an extensive stock of cattle, and become wealthy, although their mode of management was very inferior to that which has been proposed. They, however, increased their live stock in full proportion to the means furnished by the system of management employed by them.

"From first to last, they have been enabled to live better, and vastly more independently, than those who relied principally on the plough. The cause of this is evident; milk, butter, cheese, wool, meat, hides and manure, are continually increasing. It is evident that but little manure can be obtained in the beginning; however, where that little is spread, the product is greatly increased, as is also the fertility of the soil for a succeeding crop, and the grasses following it. Where a plenty of good grasses and hay prevail, young cattle will grow as much or more in one year, than they do in two when kept on pasture, fed bare during summer, and on straw through the principal part of the winter.

"It is considered proper to remark that, although many circumscribed farmers make considerable progress in increasing their live stock, their laudable enterprise, however is too often suddenly checked, before they obtain half the number of domesticated animals necessary to the proper cultivation of their grounds.

"This evil originates in the prevailing error, that huge piles of stone and mortar, or boards and scantling, are the best means that can be pursued by the cultivator to improve his farm. Hence it is, that we see almost in every part of Pennsylvania, where it is possible to effect this mistaken improvement, extensive barns and dwelling-houses standing on farms, where we do not observe half the quantity of grass, or number of cattle, necessary for the proper cultivation of the surrounding soil."

The Northern Shepherd,

Is the title of a 12mo. volume sent us by the Kennebeck Agricultural Society, for which we tender our thanks. It is a report made to that society, by a committee appointed for the purpose, upon the diseases and management of sheep. It is divided into three parts, the first on the mangement of sheep, prefaced by a short description of the various kinds among us; the second on the diseases of sheep; and the third miscellaneous. From the cursory examination which we have been able to give to the work, we think it will serve as a valuable companion to the sheep-master and shepherd.

There are some general principles laid down and inculcated which we think important ones, and which we propose briefly to notice; and although we do not intend to go into an argument to prove them to be sound, we think most of them are so palpably true, that the reader will only need to be reminded of them to approve and adopt them in practice.

Wool, and not mutton, being the great object in Maine, a preference is given to the Merinos; and hopes are expressed, that by a judicious attention to crossing, the grand point of improvement aimed at will ere long be obtained, viz. a Merino fleece upon a Bakewell body.

The South Downs seem to rank next to the Merino, as having the next finest fleece, as affording excellent mutton, and as possessing a hardiness of constitution, and a vigor and activity, which enable them to support and to thrive upon bleak and barren hills, where the Dishleys would die from exposure or starve.

"*Sheep should not be kept too high,*" says the report, "unless intended for the butcher; for it is believed to be a true maxim in regard to them—'once fat and never fat again.' If they once become fat and are suffered to fall away, it is difficult getting them so fat as they were before they began to grow poor." p. 27.

High rocky pastures are much the best for sheep.—"Nature, it seems, designed the sheep originally for a mountain animal; and although man has by art changed its nature in a surprising degree, yet he has not been able wholly to thwart her views, and the sheep loves still to feed on the hill top and cliff, where there is a pure and exhilarating breeze, and where it can shelter itself under the shade of trees, or a projecting rock, during the heat of our sultry dog-days. A high pasture should therefore be devoted to your sheep."

Salt and tar should be given to sheep.—"A piece of salt may be laid in a trough, and the sheep will lick it as they please, and if some tar be added to the salt, it will be a benefit to them, as tar is a very good stimulant when taken into the stomach, and it prevents annoyance from the different species of flies." We would recall to the recollection of the reader, the mode of administering these as practised in Spencertown, and published in our second volume. A log is hewn upon one side, which is then turned uppermost. It is then perforated upon the hewn side, with hole made by a large auger, two or three inches deep. The holes are then filled with salt, and the hewn surface smeared with tar. In obtaining the salt, which the sheep are permitted to do as often as they desire, their noses become daubed with tar, which prevents the fly from entering the nostril.

Shelter during stormy weather, at all seasons, is considered indispensable to the health of the sheep, particularly after they have been shorn. "So tender and delicate is the skin of the fine woolled sheep, and so close are their fleeces, that there is great danger of pelt-rot being occasioned by too great exposure to the chilling influence of long and cold storms."

Sheep should be brought to the barn, in autumn, in good order.—"They are thus fitted to withstand the rigors of winter much better, and they will be carried through this inclement season with much less care, and more economically than they can be if they are poor and emaciated when winter sets in." This is true of all farm stock.

Sheep require the stimulus of distension—they should be filled with something that they will eat. When fed upon green grass, a sheep consumes eight pounds a day. If this grass is converted into hay, it weighs but two pounds, and the two pounds constitutes its winter ration. To ensure health, the six deficient pounds should be made up in water, vegetables or other food.

Pine or hemlock browse, are recommended to be given to sheep in winter. "I have for near thirty years," says the writer of a part of the report, "made use of hemlock boughs as the cheapest green food." It may be added, that the resinous qualities of these boughs, promote the health of the animal and prevent disease.

Sheep should not be turned to pasture too early in the spring—"for it takes their appetite from their fodder, and as they cannot graze enough to fill them, they lose flesh fast."

Sheep should not be crowded in sheds, nor huddled together in one spot too long; "as that," says the book, "I am confident, has produced disease in my flock. In one instance, I have no doubt the pelt-rot was thus produced, and nothing saved the whole flock from the scab, but a timely application of oil to the sheep."

Open sheds are the best shelter for sheep.—If kept dry, the wind is desirable, though cold. It preserves the purity of the air, and promotes health.

Under the treatment in March it is remarked—"Take good care of your sheep this month, that they may be able to bring forth their young the better during the next." And under the treatment for April it is urged, to "make the sheep eat as much green food as possible each day. Grass is the best, if you have it; next to that potatoes. This month tests all the rest, as regards ewe sheep, for he who raises the greatest number of lambs from a given number of ewes, is supposed to be the best shepherd, all other things being equal."

We pass over the second part of the work, which treats of the diseases of sheep, and content ourselves for the present with making the subjoined extracts from the miscellaneous part.

"*Salt.*—I have mentioned that salt was considered by the Spanish shepherds as essential to the health of sheep, and this sentiment is very general in every part of Europe except England, whose situation renders the air sufficiently salt.—The same consequence from similar causes takes place here. Upon Long-Island, and elsewhere near the sea, the cattle require no salt, nor manifest a desire for it; whereas north of the Highlands, they eat it ravenously, and it is thought essential to their health. The ancients also entertained similar sentiments upon this subject. Aristotle prescribed one peck every five days, during the summer, to one hundred sheep. We should consider this a large allowance, but it would be readily eaten. They also observe, that, however good your pastures may be, the sheep will tire of them if not changed, unless their appetites are kept up by salt."

"*Transitions from high to low food.*—With all stock, it is allowed to be very dangerous to pass very suddenly from high feed to that which is scant and poor; or from plenty of green food to that which is altogether dry. Hence arises a very important maxim in respect to sheep; which is, as soon as the pastures fail, towards the end of autumn, to put them to turnips or cabbages, if we have them; and this will perhaps be found our best system with respect to turnips; to sow a sufficient quantity for our sheep, to be eaten after the grass fails, and before the snow falls, so as permanently to cover the ground."

Essex Agricultural Society's Transactions.

We always turn to these with a certainty of finding much to instruct, and something to amuse us. The transactions of 1838, which are now before us, are rich in matters of interest to the farmer and to the country; and we hope to serve up to our readers some acceptable repasts from their contents. We shall begin with extracts from the address delivered before the society at its anniversary meeting; and the sentiments which these contain, we are persuaded, will be heartily acceded to by every honest republican, who is not led astray by the phantom of speculation, or who is not bewildered in the mazes of party politics.

The scope of Mr. Withington's address, he remarks, may be expressed in the following propositions and questions, embracing the great problem now before the public mind.

Proposition I. The majority must rule.
II. The majority must toil.
III. All professions must be open and free.
IV. The majority, to rule well, must be intelligent and virtuous.
V. How shall we make them so intelligent and virtuous as to choose the toilsome professions and rule well?

We pass over the first four pages of the address, to the following

EXTRACTS.

Yes—to be a good republican it needs faith; it is necessary for the prelusive experiment. It is well known, for ages past, the MASSES of men have been rising. Ever since the establishment of corporations and boroughs in the middle ages, in every political convulsion, the result has been to increase the influence of the many and diminish the oppression of the few. Our government is one of the last efforts of these long operating causes; it was established, not for a few families, not for a titled aristocracy, not for a king, but for him that drives the chisel and him that holds the spade; and it supposes the possibility of that dubious and much-doubted attainment in human nature,—that he, who earns his bread by the sweat of his brow, may yet be a thinking being; choose his own religion and make his own laws, as well as obey them. History perhaps has very little to produce this faith of which we have been speaking. Our brightest visions must be borrowed from the future. Our hopes are founded on what man *may be;* not on what he *has been.* We read, it is true, of ancient republics; but they resemble us only in a generic name. There never was a republic that *went for man;* or was founded on the rights of man. They all formed a conventional idea of the citizen; and never went for that inheritor of will and reason, that responsible being, who derives his immortal gift from, and is accountable chiefly to God. Why should we be forever talking of Athens and Rome; of Athens with its 20,000 citizens and 400,000 slaves; of Rome, not only with its slaves, but with its myriad of idle citizens, fed from the public treasury; and where we are told, even before the age of Cicero, there were not more than 2,000 citizens who had what might be called an estate. Were these republics founded on the rights of man? Were their partial experiments, when fully unfolded, calculated to produce much confidence in our own?

The soul must animate the body; the plan must go before the execution; the theory must guide the action; and confidence in what is possible and true must inspirit the perseverance that leads to success. We often hear it lamented that so many evils should mar the beauty of our rising morn. Ah, these clouds! these fogs; these curtains of darkness over the rising sun! The mob; the radical; the popular delusion; the impracticable plan and the still more absurd execution; the libel; the inflammatory press; the sage that will not write and the fool that will; the midnight caucus and the premature nomination; the demagogue in office and the general spread of political corruption; a surplus revenue in the midst of national bankruptcy; and the dreadful shakings of credit in the commercial world; the jealousies between the opposite parts of our republics; the justling of the wheels in our delicate and complex machine; all these are evils—earthquakes, which shake our moral ground; and yet it seems to me the *chief* evil of these mortifying calamities is not seen. The chief evil is, that they go to destroy that confidence in the permanency of our institutions, which is of itself a part of their spirit. Every bad election; every wild experiment; every mob in a great city; every act of political injustice, tends to destroy that *faith* which is at once the spring of our activity and the source of our salvation. If I can discern aright the signs of the times, we are now in danger from a wide-spreading skepticism respecting the stability of republican institutions, and even the value of liberty itself. It is the dry-rot, which has seized the beams of the building, from the sills to the ridge-pole; and however silent in its progress, is seen in its mortal effects. It is astonishing how many are infected with this criminal distrust. It quenches all enthusiasm; it destroys all principle; it leads to political corruption; it makes parties a mere contest for place; in a word, it cuts off the stream of action in its head-spring, and leaves to the citizen, in his prospects, a dreary and fountainless waste. Alas! this political infidelity has crept from heart to heart, until it has become more extensive than we allow ourselves to confess. How different is this spirit from that of the last generation! Then all was credulity, principle, confidence, enthusiasm. Every oration, on the fourth of July, was filled with the most fulsome promises. A great empire! A free people! An intelligent majority! Wise rulers! The best of laws! A new example! An imitating world!! Such were the first visions of a new born nation. Now the note is entirely changed. Presumption has been followed by despair; and it is to be feared, that as some disastrous facts have weakened the principle, so the weaker principle may produce new facts, still more disastrous, until exertion ceases and liberty is lost.

The cures of those evils are many; but a very important one must come from a well-prized and well-regulated *agriculture.*

Society has often been compared to a pyramid, which owes its durability not only to solid materials, but to its skilful shape. Agriculture is the base; the ground is the fruitful mother of the best of our comforts. And it is necessary, for the welfare of any nation, that the majority of its citizens should follow the profession of tilling it. It produces the raw material. Thence come the bread and meat and wool, which nourish and clothe our bodies. It is the silent steward of the Great Father of nature, offering a kind of temporal omnipresence to the solicitations and wants of its inhabitants; various in its gifts; permanent in its location; reasonable in its restitutions and most just in its rewards.* No man that was willing to cultivate the earth and thence derive his support by the sweat of his brow, ever perished by hunger; and no nation, whose citizens kept the ranks of this profession proportionably supplied, was ever known to perish by wars or treasons, or commercial confusions; by banks or bankruptcy; by discontents and factions within; or by invasions and foes from abroad. Not that following agriculture is itself a virtue, or forsaking it essentially a vice; but a due replenishing of this employment is an indication of a healthful state in the public sentiment. It shows that the foundation of the mountain is broad; and that the top thereof, though lofty, may alike defy the electric fires and the sweeping winds of the summer and the winter cloud.

Such is the imperfect character of our most solemn investigations, and so greatly are we blinded by party spirit and passion, that whenever we are called (as we think) to oppose and overthrow any public institutions, we inflame our zeal by exposing all their defects and allowing none of their excellencies. Never was there a revolution when the merits of a conquered dynasty were carefully estimated by the victorious party. Even in institutions where the balance of evils is on the whole great, it is always found, when they are abolished, that some unthought of benefit, is lost, by a removal; nor is it until long after the excitement of the change is passed away that mankind can foot the account and fairly estimate the exact magnitude of their loss and gain.

So it was in our American revolution. We rejected the institutions of Great Britain. We threw off those aristocratic chains, they were binding upon us. We altered the foundations of society; and liberty started on a new career of more daring experiments. She was wider in her sweep; deeper in her franchises; more radical in her maxims. She professed to comprehend all men in her offered privileges and blessings. It was freedom in manners as well as in laws; her powerful sun, now in the meridian, was to melt away the last floe of restrictive ice and set every human creature on the career of wisdom as the waves dance together on the sea in equal space and freedom. But it is now found that this universal *enterprise* has its evils. There is danger, that the necessary professions should not be kept full; that multitudes should forsake the plough for the pen; that the splendid professions should be chosen rather than the useful: I have some suspicion that, in our present constitution of manners, even the multitudes of colleges in New-England may be an evil; certainly no man should hope to hide his laziness under a pretended love for literature and religion.

* * * * *

There is another evil. No heterogeneous composition can last. We have retained the *ideal* of the old system with the form of the new. They are destructive of each other. There is a silent spirit, which tinges our fancy and tinctures all our ideas of gradation and eminence. It still seems to say that one profession shall be more honorable and profitable than another, while at the same time, in theory and in practice, we throw the doors wide open and make all alike accessible to every class. The consequence is, there is a pressure to those which are esteemed the more desirable pofessions. Enterprise and honor are confined to narrow channels. An anecdote will explain what I mean. Two advertisements were recently published in a neighboring city; one for a clerk in a store; the other for an apprentice to learn the blacksmith's trade. The number of applicants for the former place was *fifty;* for the latter *not one.*

But how shall we avert the evil? It is certain we cannot reverse our republican institutions; nor restore the ancient ranks. Some plan must be devised within the sphere of manners, more suitable to the spirit of the age; more gentle in its operations; more salutary and healing in its effects. To elucidate this point is our main inquiry.

In the *first* place, then, we must bring our manners and our political theory more into harmony. Our creed must sanction our practice, and our practice must be in conformity to the spirit of our creed. We must not attempt to put the *new wine into old bottles; else the bottles break and the wine runneth out and the bottles perish;* or, in plain language, the republican spirit must be put into the republican forms; and we must be content to take the system, the whole system and nothing but the system, with all its blessings and attendant evils. If all men are born free and equal; and all professions are alike honorable, then *say so* at once; and leave the balance of the relative numbers to be regulated by the relative profits; as it certainly will be, if not controlled by these subtle, colouring ideas, inherited from other ages and antiquated systems. Two grand ideal powers are now brought into mental collision, and are shooting their moral ammunition across the Atlantic. On the one side, our theory is deeply felt among the powers of Europe. It produced the French revolution; and is still producing a deeper revolution, though silent, in the vision of eastern politicians. On the other hand, their commercial monopolies, their institutions and manners are exercising a deep influence over us. It is felt in the traveller; the summer visitant, the steamboat; their newspapers; their debates; their titles; their reviews; their wit and their metaphysics. Even the late coronation of the queen Victoria was not without its effect. The whole system of commercial wants and supplies grows up from these social forms and supplies them. Every cargo of fashionable goods creates a taste and leads to an expense unfavorable to republicanism. For my part, though no friend to sudden innovation, and wishing to place myself as far as possible from the spirit of modern radicalism, I am compelled to say, that it is my wish, that everything, in this western world, should radiate from one great central idea; that we might have republican manners; republican fortunes; republican architecture; republican books; and republican eloquence; that everything might be latently blended with that spirit, which hails the improvement and recognizes the equality of man. Let the central altar be built with unpolished stones and be tinged with the crimson of our own rustic sacrifices.

Education too should take a shape from our public prospects. Every father and tutor should educate his son or pupil with reference to the condition, which his country imposes and the duties she requires.

* * * * *

Thirdly. The human mind is, after all, governed by some very fine and invisible threads, which, though delicate in their texture, are strong in their effects. There is a latent impression of elegance, grace, beauty, which a young man gets early in life, from a thousand indeffinite causes, powerfully determining him in the choice of his profession. Woe to that man, who sees, in his youthful morning, the rainbow settle on the wrong hill; and is doomed to pursue it through life over unfordable streams and up impracticable heights. There is an idea of *the beautiful* in morals and in life, *to kalon,* the fond image from which emanates our strongest desires, and around which play our brightest dreams of felicity. It is this, which coloring all the operations of reason; governs the man; decides his choice; inflames his energy; increases his skill, and gives him the elements of success. One man finds it on the ocean; another on the land; one in war; another in peace; one in science; another in poetry. Petrarch had his Laura; and it has been seriously doubted whether she ever had flesh and blood; whether she ever existed out of poetry; whether the bard did not embody his own fancies and give to *an airy nothing a local habitation and a name.* In a certain sense, every man has his Laura; who fills his imagination, and leads him through life. Every man has some ideal of perfection and happiness after which he always reaches, though never grasping; and which modifies his pleasures and his pains from his cradle to his tomb. In vain does reason speak; in vain does experience warn; in vain may you balance against his ideal visions the collected utilities of life; if a man does not, in some degree, reach his contemplated goal, he is poor in the midst of abundance, and wanders a wretch through the world. Nor is it the young and imaginative alone that are governed by these ideal forms; the most cool and avaricious feel their power. *Their* Laura is not the same as Petrarch's; they will not write sonnets to her praise—certainly not *such* sonnets—but their views are just as ideal; and the phantom they pursue assumes her beauty and her power, solely from her relation to their temper and taste. It is not the material gold that absorbs the miser's lust; to him, as to other men, it is worthless dross; it is the ideal of being a rich man; it is the laurel of a Crœsus shading his dwelling and adorning his tomb.

**Justissima tellus* is Virgil's fine expression. II. Georgic. 460 line.

If a certain style of living seem essential to our happiness; and in the competitions of life, we are left to fall short of it; no philosophy, and I had almost said, no religion, can save the strongest mind from a degree of disappointment.

Now it was the policy of antiquity to give agriculture the first place among the professions; I allude not to pastorals; that retrospective pleasure with which, from the courts of princes and in an age of refinement, men look back upon incredible scenes of virtue in Elysian fields of bliss. But the most sober calculators, the orator and the historian, delighted to relate the story of Cincinnatus, passing from his plough to victory and from victory back to the plough—*triumphalis agricola*. The possibility of uniting the highest mental qualities, with that practical skill which makes the *desert blossom like the rose*, was strongly inculcated. It was the leading article of ancient faith; and must be so again. The man, who makes agriculture, not merely productive, but honorable; who surrounds his farm with the images of the most attractive happiness; who dwells in a neat abode, such as republican wisdom might build and republican simplicity ought to desire; who, in addition to the song of the robin, can make the music of contentment flow around his calm abode; can unite it with the intelligence of a citizen who knows his right and is determined to defend them; who knows that *this business* is favorable to mental culture and as fair a road as any to political eminence; such a man does more to encourage the profession than all other causes combined. He touches the springs of action in their centre and blesses his country and mankind. He plants the laurel beside the plough, and allures thousands to come, and after having toiled within its fragrance, to sit beneath its shade.*

There is still a *fourth* expedient. The return of those, who have been disappointed in the learned professions or commerce, to agriculture; and being happy in the return. Your father's farm!—it supported your cradle and may perhaps be destined to inclose your grave. I am aware, that these resumptions of an old employment have not always been successful. The body long disused to labor, melts beneath the summer sun; aches as it follows the plough; and the soft hand, which has worn the glove, becomes blistered as it handles the pitchfork or the spade. The stillness, too, of a country life, so soothing at a distance, becomes tasteless when it is the forced choice of men, who have trod the mart and been honored in banks. Even the song of the robin, which warbled so sweetly in pastorals, becomes harsh discord when a man hears it from a house, under a heavy mortgage; and it is the only music, which his poverty can afford. But let us not be discouraged; life is a conquest over difficulties. These returning farmers; these prodigals, who, having spent their substance, at last go home to their father's house: these shipwrecked mariners on the golden sea of fortune, who swim to the shore on the last shivered plank—after all, have some advantages. They have increased their skill; they know mankind; they have seen the world; and should they be endowed with genius and glow with a new ambition—what discoveries might they not make! Though the triumphs of mechanical skill have as yet been chiefly confined to manufactures, and some say can never be exhibited in agriculture, yet as an offset to this advantage, there is the composition; the improvement of soils. What a field is here open! How little do we know of it! How important the pursuit! How rich the reward! All the difference there is between ten bushels of corn to the acre and an hundred, is before us to awaken our invention and activity: and suppose a Newton, a Davy, a Franklin, a Whitney, to be thrown on such exigencies, how would the treasures of nature be opened! How would the best spots for the largest crops be sought out and found. Let no man despair of reaping his substance in his last days from the rugged earth, who retains either of those best instruments, a healthful body or a vigorous mind.

My fellow citizens, I rejoice, on the whole, in the exhibition of this society, and believe its tendency to be good. It reflects credit on the wisdom and philanthropy of the men who support it. Any thing that turns our attention to the great foundation of our social happiness, must be beneficial. But, I am deeply impressed with the conviction, that we need a revolution in our ideas of public and private life.

The road of enterprise must be new laid—new paved—and conduct to other objects. We are still misled by certain ideas of refinement and felicity descending to us from the Gothic ages. The public hive must have more working bees and fewer drones; and what is of equal importance, the drones must cease to engross the profits and the honors. The late concussions in the commercial world are not without their moral. They point to a different source of prosperity. Instead of thinking that all talent is to be employed on the sea or in speculation, we must turn it to a new channel; it must guide the plough; improve the soil, and carry agricultural skill to its last perfection. We shall always be an enterprising nation; I hope we shall always be a moral one. But that enterprise must flow in a wider channel; that morality must be founded on a better faith. Perhaps it would not be impossible to describe the circle that bounds the last expansion of the republican idea. When two young men, entering on life with equal abilities and virtues, would not turn up a copper for the choice of a profession to ensure their future success and distinction, then, and not till then, will the republican idea be carried out to its full perfection.

REMARKS.

The root of the evils complained of, and which seem justly to have excited the doubts, if not the fears of the orator,—the want of faith in the permanency of our republican institutions; the general rush to the learned and mercantile professions, for fame, fortune and fashion,—the idol Laura; and the neglect of rural pursuits,—the root of these evils, we think, lies in the defects of our system, or rather want of system, of agricultural education. Give to rural, the education which we give to professional labor,—improve the mental powers of the agriculturist, too, as you do those of the lawyer and doctor, and you will raise him to the same scale in society; and surely when this is done, there are too many substantial inducements to rural life, to apprehend any serious deficiency in its labors. Education, if it cannot, like the lever of Archimides, be made to move a world, can be made to move and model its inhabitants. Education has a controlling influence in after life. It makes men Christians, it makes them Mahometans, it makes them Jews, it makes them Pagans; it makes them ministers, doctors, lawyers; and, had we professional schools of agriculture, as we have of law, divinity and medicine, it would make thousands farmers,—intelligent, useful farmers—real working bees. But, alas! we have no professional schools for the farmer—nothing to enlighten his mind in his business, which is the great business —*emphatically* the great business of our republic. We profess to have adopted the *principles* of equality, while we are fast running into the *practices* of aristocracy. We impart to the few, in our system of education, facilities for lording it over the many. Hence, the great tendency thitherward, and hence, the importance of the great agricultural class in the right management of our political affairs.

We are strongly of the impression, that the establishment of professional schools of agriculture, in which the mind as well as the hands should be instructed—and particularly as normal schools for the instruction of teachers, would in a few years work a salutary revolution in the habits and fashions of society, and avert many of the foreboding evils with which our republic is threatened.—*Conductor*.

Method of using the Chloride of Soda.

A translation of A. G. Labarraque's method of using the chloride of soda, has been kindly sent us by Jacob Porter, the translator. This chloride is the most powerful disinfecting agent known, and has been found of great use in dressing ill-conditioned sores, and as a means of purifying unhealthy places, and disinfecting animal substances. It is sold in a liquid form, at the apothecary's by the bottle. It is used diluted with water. A bottle of the liquid, which costs but a few cents, will serve a family sometime, for disinfecting the air of vaults and other foul places about dwellings, purifying the air in sick chambers, in cellars, &c. Its great utility in lazarettoes and hospitals, and, in Asia, in preserving from the plague, seems to have been tested and proved by officers of the French government. At this season, it is peculiarly beneficial. We subjoin some of the directions for its use.

"For ill-conditioned ulcers let a glass of the chlorated liquor be mixed with five times its quantity of pure water, and in this mixture dip the lint with which the ulcers are to be dressed. The dressings should be applied twice a day. If the sore become red and inflamed, this mixture should be still further diluted; if, on the contrary, the sore does not change its appearance, it should be dressed once or twice with some chloride with only half its quantity of water, so as to bring on a slight inflammation, which is indispensable for causing atonic ulcers to pass to a state of simple sores. The healing will then go on rapidly. At the time when the chloride is applied to the ulcer, the fœtid smell is destroyed.

"Gangrene, hospital putrefaction, ill-conditioned burns and scalds, old syphilitic ulcers, corroding herpetic affections, and the like, should be treated in the same manner.

"Cancer in a state of supperation may be disinfected with some lukewarm or cold water, containing a twentieth of the chloride soda.

"For ulcerations of the nasal organ, the throat, the palate and the gums, the chloride should be diluted with eight or ten parts of water. It will, nevertheless, be necessary to touch these sores with a little lint moistened in some pure chloride.

"For the scald, head the chloride should be mixed with only an equal quantity of pure water, and the parts affected be moistened with this liquid twice a day.

"Great advantages have been obtained from using the chloride very much diluted in water, for all the purposes of the toilet. In a dose of from 25 to 40 drops [not to be taken internally,] it acts as a bracing and preserving wash, prevents the spread of herpetic eruptions, and cures certain diseases of the skin.

"The air of sick chambers, and the patients themselves, may be purified by mixing a spoonful of the chloride and six spoonfuls of water in a plate, and setting it under the patient's bed; indeed, several plates with the diluted chloride may be placed in the same apartment if necessary. In this way the exhalations may be destroyed as soon as they are produced. It will be necessary to renew daily the chlorated water contained in the plates.

"In all places where there is a crowd of men or animals, whether sick or healthy, the air becomes corrupted, and acquires deleterious properties, owing principally to the animal exhalations. These exhalations may be destroyed by sprinklings of the chloride, diluted in from 25 to 30 parts of water; or by setting in these places (and they may be out of sight,) some vessels containing the chlorated water, which can never be in the least injurious, whatever may be the quantity. This method of purifying the air is indispensibly necessary in lazarettoes, hospitals, prisons, poor-houses, manufactories, churches, seminaries, convents, halls of study, and dormitories in colleges and boarding-houses, cabins of ships, court rooms, crowded theatres, saloons when filled to excess on great occasions, and the like.

"Sprinklings of the chlorated water will be more especially necessary whenever an epidemic or contagious disease prevails; they should be made in order to guard against the deleterious influence arising from the neighborhood of marshes, the rotting of flax, hemp and the like. They will likewise be serviceable in the diseases of domestic animals, in places where silk worms are raised; finally, in all places where the air becomes charged with exhalations, which, on being accumulated, produce fatal effects.

"In cases of asphyxia, produced by the exhalations of vaults, sewers, or any considerable masses of putrefying animal substances, it will be necessary for the patient to breathe the concentrated chloride; and his chamber should be sprinkled with the chlorated water, so as to subject him to the influence of the disinfecting agent.

"It is often necessary, sometime from a tender, pious feeling of regret, to preserve for a long time the bodies of deceased persons. A fœtid odor appears more or less readily, according to the temperature of the air, the state of the patient's body at the time of his decease, or the disease that terminated his life. This decomposition may be suddenly arrested; indeed, it may be prevented by sprinkling the body with some chloride diluted with water. For this purpose a bottle of chloride should be mixed with twelve bottles of water; in this mixture a linen cloth should be wet, laid on the body, and sprinkled occasionally with the liquid."

Influence of Climate upon Seed.

We received, last spring, twelve ears of Dutton corn from Mr. Osborn, of Oswego county, his residence differing from ours, in latitude and altitude, about two degrees. We planted with this seed eight rows across our field, the residue being planted with seed of our own raising. The Oswego corn tasselled two weeks earlier than that from seed raised in Albany, thus showing six or seven days' difference for a computed degree of latitude, in the earliness of the crop—the northern seed giving the earliest crop in a ratio inverse to the forwardness of the spring. This will serve as a hint to farmers in districts where corn is liable to be cut off by early autumnal frosts, to obtain their seed from a more northern latitude, or from a district of higher altitude.

Hussey's Patent Reaping Machine,

Is exciting considerable attention in Maryland, and it has been recommended by the Philadelphia Agricultural Society, and by a society in Maryland. A Maryland correspondent speaks of it as follows:—

"I know not whether the news may not have already reached you, of a new mowing machine, invented by Mr. Hussey, which adapts itself to all surfaces, up hill and down, not encumbered with stones and stumps, and doing its work better than can be done by hand, to the amount, in a day, of what four of the best cradlers could accomplish. The executive powers of this machine are very credibly vouched by a Mr. Carroll, who has one or more of them in use on a large farm. His moving power is a pair of strong horses. Before the thing can reach perfection, we must employ the electro-magnetic impulse, which your last legislature thought no humbug."

12th Anniversary of the American Institute.

The annual exhibition will commence on the 7th of October, at Niblo's Garden, in Broadway, New-York. The contributions from exhibitors will be received on Thursday, Friday and Saturday immediately previous. The anniversary address will be delivered on the evening of the 10th October. The Silk Convention will be held on the evening of the 11th; and a ploughing exhibition will take place at Harlem on the first Thursday of September, at two o'clock P. M. We intend to give the address of the Institute in our next number.

Sales of Short-Horn Cattle.

It will been by our advertising page, that a sale of the Messrs. Allens fine stock of Short Horns will take place at Tonnewanta, near Buffalo, on the 10th of September, and that a sale will also take place at Powelton, near Philadelphia, of several imported animals, belonging to the celehrated herd of Mr. Whitaker, of England, on the 20th of September. The Messrs. Allens have taken much pains to procure the best stock to breed from, and from the appearance of their herd two years ago, we have no doubt they have succeeded in rearing superior animals.

An Idler

Cannot bear to be inquired of as to his daily business. Every answer to such a question is to him a subject of self-reproach. He has either attended to no business, or to the business of others.

AN INDUSTRIOUS MAN

Will answer such interrogatories with pleasure. His responses will imply self-approbation: he has been employed in providing for the wants of himself and family, and perhaps doing good to others.

---

* After all, mankind, especially the young, will be governed by their ideas of the beautiful more than utility; in politics, morals, religion, and general life: nor would a benevolent man wish to exterminate this fundamental principle of our nature. But there is all the difference in the world, between conventional beauty, the beauty of fashion and expense; and that, which is simple, natural and eternal. Let us look at a few particulars: a rich shawl to a young lady's eye is beautiful; so is a rose. But the one is a conventional beauty; the other a natural. The one lasts while the fashion lasts; the other, i. e. its essential beauty, until flowers shall be no more. Take the fluctuations of female dress: sometimes its beauty depends solely on the fashion; sometimes it approaches to the everlasting laws of nature. The old stays and high-heeled shoes of Queen Ann's day, were mere conventional beauties; the Grecian dress is natural and essentially beautiful. Now it seems to me, what we are to seek is—that cheap, simple, essential beauty, which promotes the progress of mental refinement, but never leads to the expense which plunges families and nations in ruin. Let the conventional and natural meet in one line of inseparable union.

The idler is the drone which lives on the public hive, but adds nothing to its stores.

The other is the laboring bee, which works not only for itself, but for the commonwealth.

Let the young imitate the latter, if they would not, like the drone, become worthless outcasts.

Capacity of Rain Water Cisterns.

The following table, showing the number of gallons of water contained in cisterns of the diameters mentioned, for each foot of their depth, is copied from a communication in the Farmers' Cabinet.

Diameter.	*Gallons in 1 foot.*	*In 10 feet.*
5 feet,	120,	1,200,
6 "	170,	1,700,
7 "	230,	2,300,
8 "	308,	3,080,
9 "	390,	3,900,
10 "	480,	4,800,

So that a cistern 6 feet in diameter, and 10 feet deep, will hold 1,700 gallons, or fourteen hogsheads.

THE BUDGET.

Silk Reel.—It is out of our power to give to Mr. Geo. Bigelow the advice he asks of us in regard to silk reels, not having used any, though we have no hesitation in saying, that the silk business will ultimately do well, where it is managed as a family concern.

We have had several inquiries for the constitution of the New-York State Agricultural Society. We have complied till we have not a copy left, and till we are unable to procure one for publication.

Several correspondents have asked our opinion as to the best machines and implements, as threshing machines, straw cutters, cultivators, drill-barrows, &c.—These are delicate questions to answer, especially as we have personal experience with but few of those which are offered for sale. All we can do is to speak well of those we know to be good. This we have done freely. But we cannot speak of the comparative merits of those which we have not tried. Mr. Pitts, of whose threshing machine we have spoken in high commendation, is now located in Albany, and we have referred the inquiries relative to his machine to him in person.

Acknowledgment.—From W. Donaldson, a description of the Swartaria Mining District, illustrated by diagrams.

CORRESPONDENCE.

Plans and Estimates for Farm Dwelling-Houses.

Distrusting our own judgment in this matter, we placed the several Plans and Essays on Farmers' Dwelling-Houses, which we had received, in the hands of an eminent disinterested architect and builder, and an intelligent farmer, to examine them, and advise us which was best entitled to our premium. After carefully examining them, the gentlemen have given it as their opinion, that the plan submitted by John Cain, of East-Clarendon, Vt. on account of its greater convenience, good proportions, and economy of structure, is entitled to a preference; and we therefore award to Mr. Cain our premium of TWENTY DOLLARS, in such article of plate as he may select. The plan of Mr. Jewett, of Weybridge, Vt. having been considered the second best, we tender to Mr. Jewett a bound set of five volumes of the Cultivator, as a gratuitous premium.

As the competitors have been at considerable labor in furnishing us plans and estimates, and as, moreover, different persons may select different models, according to their means and their taste, we publish them all, omitting the details of the estimate of the cost, except Mr. Cain's, which we give entire, as the price of materials will materially vary in different districts. The estimated aggregate of cost is, however, stated at the foot of each communication.

If this effort to improve our farm dwelling-houses, to render them convenient, and to economize the cost, shall, as we think it will, afford useful hints to those who intend to build, and serve to lessen the burthen of female labor, in the discharge of domestic duties, we shall feel happy that our premium has been productive of public good.

East Clarendon, Vt. March 18, 1839.

Jesse Buel, Esq.—Sir—I am by profession an architect and builder. I have built a great many dwelling-houses, but for the last five years past, I have been entirely employed in planning and superintending the erection of meeting-houses in this state. My place of residence is in the town of Clarendon, but I am at present superintending the erection of a splendid meeting-house in the town of Danby, (Rutland co.) and while here, a friend has let me have the number of the Cultivator for April last, in which I find a premium of $20 offered for the best plan of a farm house, to cost from $1,500 to $2,000. Supposing, as I do, that such plans as may be sent in will be inspected by a committee appointed for that purpose, and should I be aware that such committee were architects, I should not enter as competitor, because they might give preference and premium to one of their number, through friendship. But as I am of opinion, that the committee appointed to decide on the merits of the plans, specifications and estimates presented, will be composed of gentlemen having higher and better motives than favoring friends against merits, I therefore send you enclosed four plans, three ground and one elevation plan; also, a specification or description of the manner the several parts of work shall be done. With the plans and specification, I also transmit to you an estimate of the expense of building, embracing the several kinds of work and the different materials.

Supposing that a small house, tolerably well finished, would be more acceptable to farmers generally, than a large one not so well finished, I have adopted 40 feet long and 28 feet deep, (or wide,) with an addition in the rear 24 by 20 feet. My great object has been to have all the convenience possible in a house of the above size, and a strict regard to proportion. And I flatter myself, that the enclosed plans, for cheapness in building, convenience and proportion, will be found worthy of a candid perusal. I only regret, that I cannot present and explain them to you personally, to remedy which, I must give a particular description of the several parts. I would here remark, that as a cellar is of great importance, particularly to a farmer, I have taken all pains to make it convenient, and have divided it by interior walls, which adds much strength to the floor above, as well as convenience below.

SPECIFICATION.

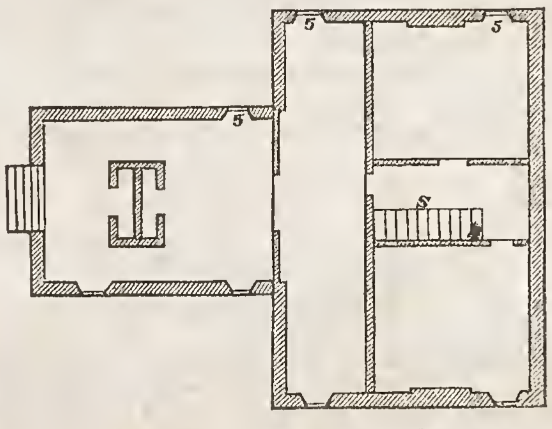
Stone Mason's Work.—If the soil you select for the site is wet, swampy or moist, dig low enough to evade the frost, and fill the trench with cobble stone, hammered down solid, upon which erect a cellar wall laid without any mortar, to the surface of the ground, which would probably be five feet; from thence up lay in mortar. Let the walls be two feet thick, and eight feet high, leaving spaces after getting up to the surface of the ground, for cellar windows, perpendicular to the windows of the principal story. Be careful to have none of the stone project outward, where the frost may affect, because such stone must either break or raise the whole fabric.

Carpenter and Joiner's Work.—The timbers composing the roof ought to be got out to such a size as not to be too weak, and at the same time not too heavy, or they will have a bad effect on the walls. The doors to be six pannels, with mouldings on both sides the principal doors, and on one side of the more obscure ones. The doors entering into the two front rooms on the principal story, to be cased with philacters; those not attached to front rooms and lobby, to be cased with a plain casing, with a returned $\frac{5}{8}$ths laid on the edge, and an one inch Grecian ovelo for land moulding. The windows to have check rail sash, and the frame grooved to receive parting lands; sash 1½ inches thick.

I have made the plans and estimate, &c. for a brick building, the walls to be one foot thick.

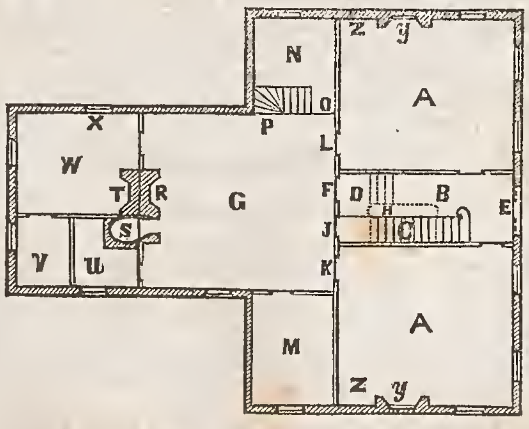
As my business is such, I have not now time to give a proper specification; suffice it to say, that in my estimate I have calculated the price of materials as they could be obtained in the town of Rutland, Vt. as in different parts of the country the price would vary, and even in neighboring towns. I have, also, in making an estimate of the cost of building a farm-house according to the enclosed plans, calculated on a plain, good workmanlike building.

Plan A.—[Fig. No. 23.]



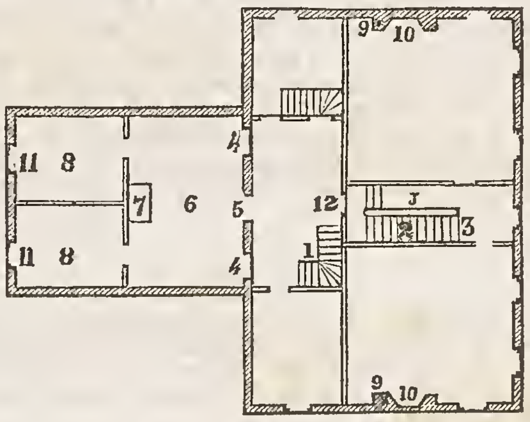
On plan A, you will observe, the walls are two feet thick. It is the ground plan for foundation wall, and shows the openings for the windows, and one opening for an outside door, with the steps to descend to cellar. S is the stairway that lands in the kitchen. The particular place for the different kinds of sauce, &c. I have left to the option of the builder.

Plan B.—[Fig. No. 24.]



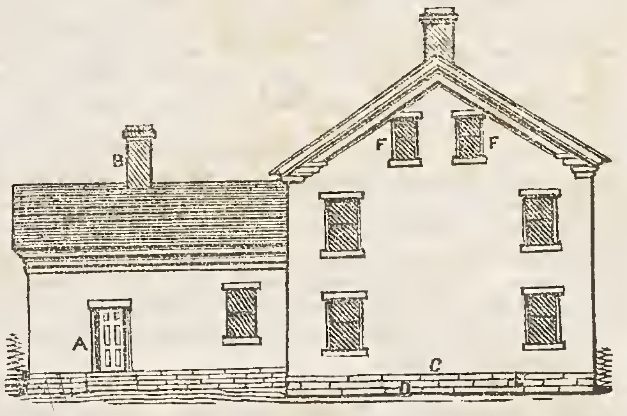
Plan B, is the ground plan of the principal story. A, A, the two front rooms. B, the lobby. C, the principal stairway, landing on the square platform D, which platform is seven feet above the lobby floor, so as to admit a passage underneath from front entrance E, through the doorway F, leading into the kitchen G.—The stairs are built on a geometrical construction, turned on a cylinder at H, and continuing from platform D, three steps, and landing at I, on plan C. The doorway marked J, leads to the cellar stairs, which go down underneath the principal stairs. K and L are doorways leading from the kitchen to the two front square rooms. M, a bed-room. N, a bed-room, with its door leading into the kitchen at O. P, the doorway and stairs (as back stairs,) leading into the room Q, on plan C. R, S and T, on plan B, are fire-places for kitchen and back kitchen. S, the oven. U, the buttery. V, pantry. W, back kitchen. X, back door. Y, Y, fire-places. Z, Z, cupboards.

Plan C.—[Fig. No. 25.]



Plan C, is the ground plan for chamber floor. Fig. 1, the stairway to the garret; 2, that portion of principal stairs seen from lobby, 3, with the three steps landing at J. The rear part of the house is intended to be only one story high, which admits the windows, 4, 4, above the roof of said back part, to light room Q. 5, is a doorway leading into room 6, which is over part of the kitchen; 7, kitchen chimney; 8, 8, bed-rooms; 9, 9, the flues of the fire-place, on plan A; 10, 10, fire-places for the two square chambers; 11, 11, two windows in gable end of rear part. The room 6, to be lighted by two sky-lights, laid level with the shingles, with zinc or lead round the frame, to prevent leaking; the glass to lap as the shingles do, or as the roof of a hot-house. The remainder of plan C will explain itself, the rooms being bed chambers.

Plan D.—[Fig. No. 26.]



Plan D, is an elevation view of the end of front part, and side view of the back part. A, the door marked X on plan B, and B the chimney 7 on plan C. C, the marble water table. D, underpinning, or that portion of the cellar wall seen above the surface of the ground at E, E, E. I should have shown the cellar windows, marked 5, 5, 5, on plan A. F, F, are the garret windows, the chimney brought up between them. I have not drafted a front elevation view, supposing that the plan B, with the front entrance door and two windows each side, and plan C, with the five windows placed as they are, will show all that is required.

Some of the advantages or conveniences of these plans are, having the kitchen so near the centre of the house, and the buttery and two bed-rooms so convenient to the kitchen; also, having the cellar door and back stair door lead out of the kitchen, and having the square rooms, A, A, as dining room and sitting room so convenient to the kitchen. I would here state, that from platform D, on plan B, to doorway 12, on plan C, there must be three steps, as at I, on plan C.

ESTIMATE OF THE EXPENSE OF MATERIALS AND WORK,
as they could be obtained in the town of Rutland, Vt.

68,000 brick, at $4 per thousand,	$272 00
Laying 68,000 brick, including board and tending, at $2.25 per thousand,	153 00
200 bushels lime, at 25c. per bushel,	50 00
800 bushels sand, at 2½c. per bushel,	20 00
6 boxes glass, at $3.12½ per box,	18 75
7 cwt. nails, at 6¼c. per lb	43 75
9,000 feet lath boards, at $4 per thousand,	36 00
5,000 feet lining boards for floors, at $4,	20 00
(If the floors were single and matched, the cost would be about the same, the work of matching being extra.)	
5,000 feet spruce floor boards, at $10 per 1,000,	50 00
2,500 running feet of rafters and joist, at 1½c. per foot,	37 50
800 feet square timber, at 3½c. per foot,	28 00
20,000 pine shingles, at $2 per 1,000,	40 00
Brads, locks, latches, hinges, screws, &c.	30 00

10,000 feet pine stuff, at $20 per 1,000,.......	200 00
104 feet marble water table, at 25c. per foot,..	34 68
150 feet marble window sills and caps, at 34c. per foot, ...	50 00
2 set polished jambs and mantles, at $10 each,	20 00
2 set common do. $4 each,.....................	8 00
Plastering, including board and tending,......	50 00
Painting, do do	75 00
Carpenter and joiner's work, do	500 00
178 perch of stone wall, the laying of which, at 50c. per perch, including board and tending,	89 00
Total,......	$1,825 68

The above doth not include the getting out and drawing of stone for basement wall, as the expense would depend on the distance, &c.

I have not time at present, to make an estimate on the cost of a wood building, no further than to remark, that here, where pine clapboards are $15 per thousand, besides drawing ten to fifteen miles, and as a frame building would require more nails than a brick one, and the work of framing and covering extra from a brick house, would cost about as much as the laying the brick; and it is my opinion that a brick building of the size and description herein mentioned, would cost from $150 to $200 more than a frame building, finished equally as well. Yours respectfully,

JOHN CAIN.

Weybridge, Vt. January 17, 1839.

Mr. Buel—Sir—Perhaps you could not direct the attention of the farmer to a subject more interesting and useful, and one that would originate so many different opinions, as the elevation and ground plan of a farm dwelling-house.

The inquiring mind and critic may say that the style is either too plain or too expensive—some would admire a story and a half, others two—one may want a fire-place in each apartment, and others would prefer stoves. In choice of materials, some would prefer brick, and stone or wood; and finally, in an edifice of this nature, we are more apt to seek for the discovery of some inconvenience and faults, than we are to give credit for the good.

That others may be induced to present some better drawings, I take the liberty to offer the following, which you may submit for the consideration of your honorable committee, which is the drawing of the ground plan and front view of a wood dwelling-house, 30 by 38 feet, two stories high; a building in a direct line attached in the rear, 20 by 30 feet; two wings, on each side of the main building, 19 by 20 feet. It may front either to the east or west, by inverting the ground plan. The whole plan may be diminished in size, and nothing in the plan prevent the main building being erected only one story and a half. The cellar under the main building laid with stone four and a half feet, the remaining two and a half feet a vacuum in the wall round one inch wide, is best done by raising the two and a half feet on the inside by a course of brick, which vacuum prevents the penetration of frosts to the cellar. In the first place, the farmer's wife considers it very important, that the kitchen should be convenient to each apartment above and below. I would recommend a flue leading from the fire-place to the cellar, to conduct the ashes into a vault which may be so constructed as to make a safe and convenient smoke-house.

The cost of the materials depends on the country where it is erected. Wood, brick, stone, iron, and mechanical labor can be obtained in this section as cheap as any part of the United States. A house of this description can be finished in good, comfortable style, for fourteen hundred dollars.*

In giving the dimensions of the rooms, I have made no allowance for the walls and partitions. Respectfully yours,

SOLOMON W. JEWETT.

EXPLANATION OF THE CUTS.

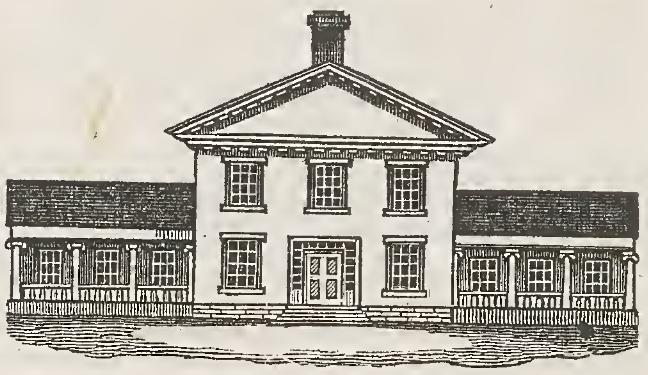
[Fig. No. 28.]

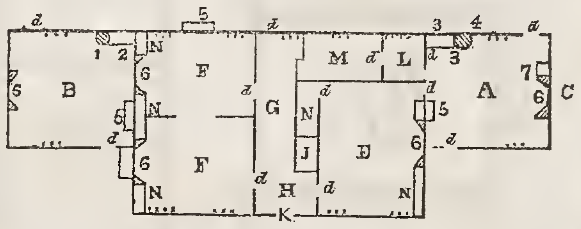


Princetown, N. Y. February 1, 1839.

Mr. J. Buel—Dear Sir—I have been looking for some time past, in very new number of the Cultivator, for a farm dwelling-house making its appearance, for the best plan of which you offer a very liberal premium. But I have looked in vain, and as the year has almost expired, I begin to think that surely none has been offered. Building is always attended with heavy expenses, and when badly planned, much of the comfort and convenience, which would otherwise have been enjoyed, is lost, to say nothing of the money uselessly expended. Rather than that your good intentions in a matter of so much importance should be frustrated, I have concluded to send you a plan (such as it is,) to commence with; for if architects will not condescend to do the work for us, we must *try* to do it for ourselves. If it meets with your approval, so far as to think that it will warrant the expense of publication, others may be induced to point out its defects, suggest improvements, or offer a better. If any should think the plan too extended, and of course too expensive, it may be cut down to meet their views, 1st. By omitting one or both wings; 2nd. By cutting off the end next to the laundry, retaining the hall; or, 3d. By rejecting the second story.

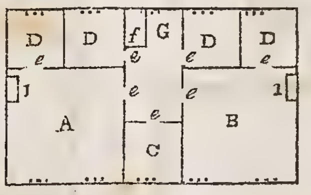
Respecting the cost, as the building is supposed to be of timber, it will depend somewhat on the price of stuff where it is to be erected. Not having the requisite experience myself, I submitted the plan to a mechanic, requesting him to give an estimate of the expense.—His opinion was in general, that it would cost from $1,500 to $2,000, to finish it in tolerably good style. The cellar walls, should be built with good mortar, and raised two feet above the ground, and the cellar divided into two apartments, one of which is to be solely appropriated to dairy purposes.

[Fig. No. 29.]—Ground Floor.



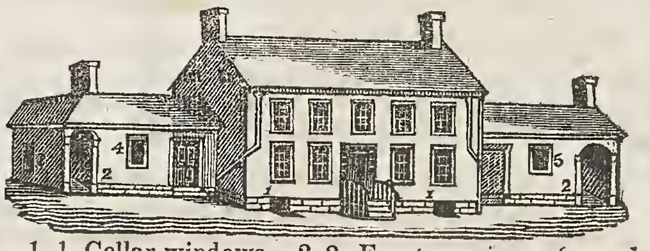
The main building is 26 by 46 feet; length of posts 22 feet. A, the kitchen, and B the laundry, are each 18 by 20 feet; length of posts 11 feet. The wood-houses, C, C, are too-falls to the ends of the kitchen and laundry, 10 feet wide, extending 10 feet in rear of the building, where they are 20 feet wide and double roofed; (they may be extended back at pleasure;) openings inward, the openings in front furnished with neat doors. E, sitting-room, 16 by 18. F, F, two rooms, 12 by 16 feet each, with folding doors separating. H, hall, 10 feet wide. I, stairs, 4 feet wide. G, continuation of hall, 6 feet. K, front door, 4 feet. d, d, d, d, doors. L, pantry, 8 by 8. M, store room, 8 by 14. N, N, N, N, N, closets. 1, 2, cistern and sink in laundry. 3, 4, cistern and sink in kitchen. 5, 5, 5, doors to cellar. .... dots, shows the places for the windows. 6, fire-places. 7, oven.

[Fig. No. 30.]—Second Floor.



A and B, two rooms in front, 16 by 18 feet each. C, clothes room, 10 by 10. D, D, D, D, bed-rooms, 9 by 10 each. e, e, e, &c. doors. f, termination of stairs. g, winding stairs to garret. 1, 1, chimnies.

[Fig. No. 31.]—Front View and Elevation.



1, 1, Cellar windows. 2, 2, Front openings of wood-houses, with doors. 3, Wood-house running back 10 feet in rear of building. 4, Laundry. 5, Kitchen.

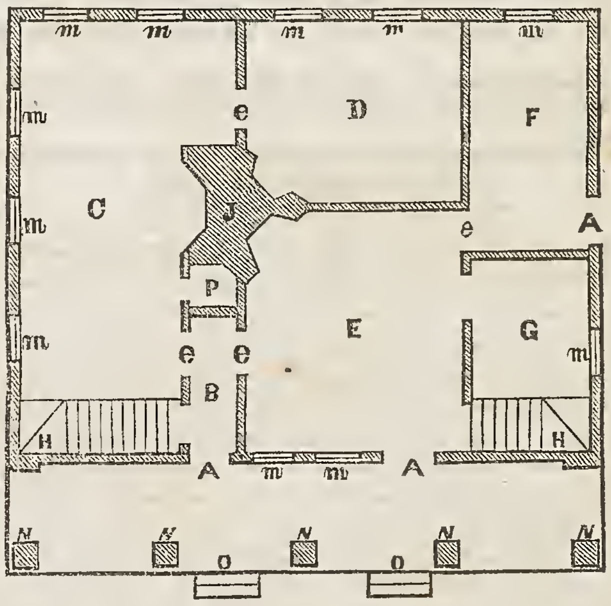
JAMES SMEALLE.

Farmington, Conn. January, 1839.

Judge Buel—Dear Sir—I send you a plan of a farm house, not so much for the purpose of competing for the premium you have so generously offered for the best, as to make it the foundation of some thoughts I wish to offer on the subject of buildings, generally. Before I do this, however, I will go through with my plan, and must frankly say of it, that it has nothing to recommend it but convenience. Architects will condemn it for want of regularity, order, and due proportion. I can only say to this, I am no mechanic; the great objects to be gained are, utility, adaptation to the use for which it is erected, suitableness to the wants of the class occupying it, economical in expense, &c. If, with these essential requisites, the mechanic can present a plan with more fair proportions, more beautiful in appearance, and more substantial, he shall have my thanks. Without these, he ought not to have the thanks of any. But to the detail.

Accompanying this, I send you two drafts; one of the ground floor with its several apartments and references, the other its elevation, with a side view of its entrance and a veranda attached, on a scale of one-eighth of an inch to the foot. The estimation of expense is calculated on more windows than the draft presents, so they may be reduced if desired.

[Fig. No. 32.]—Ground Floor.



A, doors. B, hall or passage. C, front room. D, bed-room. E, common room. F, store room. G, pantry. H, stairs. I, chimney. e, inside doors. *m*, windows. N, posts sustaining veranda. O, steps. P, closet.

It has five apartments on the ground floor, and a small landing place, or hall, viz:—a sitting room, a common room, a bed-room, a pantry and a store room. Can any one of these be dispensed with? All are necessary —all are convenient to one another, of suitable size, and well adapted to a family carrying on farming. The objections are, the sitting or parlor room is not well proportioned, and the division between the common and bed-room comes too near the fire-place, causing or placing the fires in the corner of each room. To these it may be replied, that the end of the sitting-room next the stairs may be fitted with a sliding partition, for a library for the family, and thus make the room in due proportion; and the sleeping-room may be fitted without a fire-place, and warmed by a stove, and the chimney placed near the centre of the side of the common room. The entrance to be on the south side, on account of the northern blasts of winter. In the view, I have presented a veranda, extending along the whole southern side, exhibited as adding to the convenience and appearance of the house, although not included in the estimate, and not considered absolutely necessary; but for the comfort of shade in summer, and some protection from storms in winter, considered very desirable.

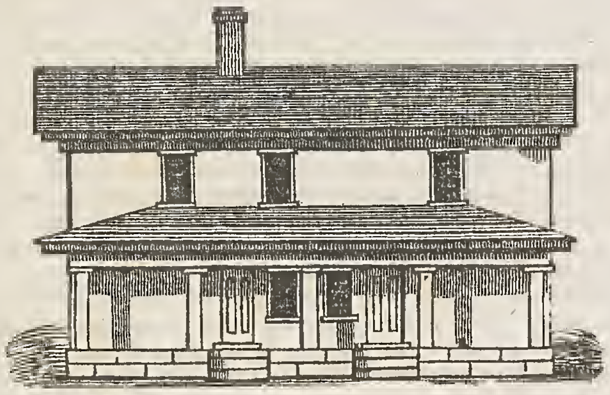
The second story to be divided into six sleeping apartments, (or more if thought necessary;) and here I would say, I should prefer having but one story to a house, but for the greater economy of two, the same amount of roof (the most expensive part of our buildings,) covering twice the amount of space, compared with a one story house. The stairs to the second story have their entrance from the hall, and a second flight from the common room, and then into the cellar under the last, the entrance from the pantry. The store room may be converted into a cheese room by dairy farmers. The size is 39 feet by 30, (varying according to the number of the family)—sitting-room 15 by 25 feet—common 15 by 18, and sleeping 15 by 12—pantry and store-room 9 by 12½ each. Three entrances, two on the south side, into the landing place, one between the sitting and common room, one into the common room, and one into the store room; there are 3 or 4 windows to each story on the front or end standing to the west on the plan, and as many as needful on the northern side and each end; one chimney, which can be reduced in size if stoves are contemplated for warming the house.

---

* Mr. Jewett subsequently sent us his estimate for wood, brick and stone; and for the two latter materials the cost is estimated at $1,450.—*Cond.*

The cost, including cellar and painting, built in a plain but substantial manner, estimated at the market price of mechanic labor and materials for the whole, falls a little short of eleven hundred dollars, but say in round numbers $1,100. I think that although the price of materials and perhaps labor may vary in different sections of our country, the cost of such a structure will not much exceed that sum in any part of it.

[Fig. No. 33.]



And now to the main object of my communication.—I have long looked with regret upon the habits of my countrymen, of estimating the present cost of any structure they are about to build, without extending their views to posterity. Cheap buildings, that will answer for the present, with perhaps a little ornament for outward show, is the rage. This is eminently so in building bridges, houses, barns and out-buildings. Now it seems to me, that economy alone would dictate to him who is to build, to take into consideration durability as one of the first elements in his calculation, and if he finds that a stone structure, which will endure say only thrice the length of time of a wood building, at from one-eighth to one-quarter increased out-lay at the outset, will, in the end prove much the cheapest; and add to this, the trouble and vexation attendant on building, which every generation must go through, if we follow up our present habits, gives greatly the advantage to durable structures. I have been led to make a calculation of the comparative expense of an entire wood building, with one of stone, and I find the difference is not by any means so great as is generally believed. I estimate, in the plan I have presented, the cost of timber, boards, nails, paint and labor necessary for the outside of such a house, and which would not be used in one of stone, to be $245. The cost of stone for walls and labor for the same, would be $320. The roof and the material for the inside will be equal for each, so that the difference is the small sum of $75. I am aware that the expense of stone will vary according to the facility of procuring them; but when we take into consideration the fact, that small stone of almost any shape, well laid in good lime, will make as good walls for buildings as any other, and that but few sections of the country but that have them in quarries or scattered over the surface of the soil, the expense will not be so greatly variant as we should at first expect. I have estimated the cost per perch of stone, including laying, at $1.50, but a house has recently been built in this vicinity, which cost but $1.12 per perch. I think, therefore, that $1.50 per perch may be a fair estimate, in ordinary circumstances, of the cost of stone work for buildings—and who can doubt the greater durability and comfort of such houses? Let the moss covered cottages of our father land, which have from generation to generation stood firm and undecaying monuments of the wisdom of our ancestors in building, speak for the first; and for the proof of their superior comfort, a neighbor of mine built a stone house fifty feet square, which he has sufficiently warmed for the two past years, at an expense of $25 per year in wood fires. It is true he used stoves, but he attributes, as one great cause for this saving of fuel, the imperviousness of his walls to the cold air. If this is true, that stone houses need so much less fuel to warm them, and I cannot doubt the fact, the saving of fuel alone would pay the extra expense of stone houses.

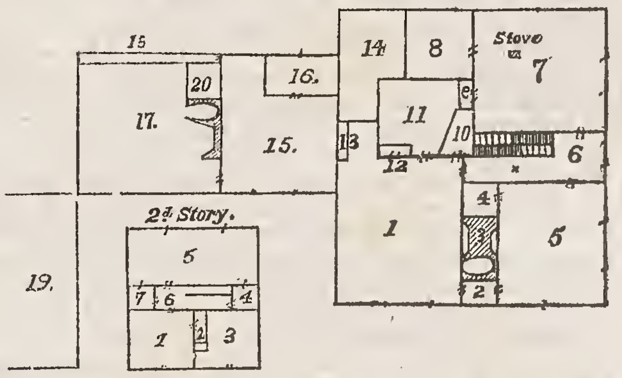
But I am extending my communication farther than you can spare space to occupy, and I will forbear, only suggesting a thought or two regarding roofs. Shingles are becoming scarce and inferior in quality, and we must look for a substitute. Slate are expensive, liable to break, and I suppose not quite tight; (of this, however, I have no personal knowledge;) and in casting about for a good covering, sheets of zinc have appeared to me to be a desirable article. It has one good quality, at least; it will not rust like tin. Cannot some of your correspondents tell us where it has been tried, and how well it answers? Such knowledge would be very desirable to future builders.

Respectfully yours,
EGBERT HAWLEY.

Derby, Vt. 4th Feb. 1839.

Judge Buel—Dear Sir—I send you the plan of my dwelling-house, with the improvements which several years' occupancy have suggested. In size it is 38 by 30 feet, built of a planked frame, with one tier of brick on the outside. This serves to exclude cold and moisture more effectually than any other material. Cellar as large as house, 7½ feet deep. The conveniences of the inside will be seen from the rough draft annexed.

[Fig. No. 34.]—Ground Plan.



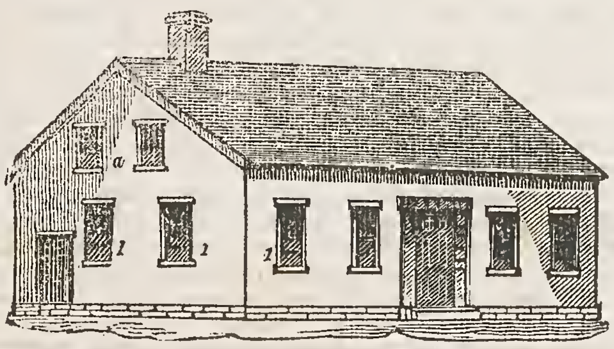
No. 1, Kitchen, 14 by 19 feet. No. 2, Entry or passage to No. 5. No. 3, Fire-places and oven. No. 4, Closet. No. 5, Sitting room, 11½ by 15 feet. No. 6, Front entry, 8 feet wide. No. 7, Parlor, 15 by 15 feet, warmed by stove, the pipe passing into chimney resting on beam at *a*, (Fig. No. 35.) No. 8, Bed-room, 8 by 9 feet. No. 9, Cupboard. No. 10, Place for hardware, brooms, &c. at the entrance to the cellar. No. 11, Bed-room, 8 by 9 feet. No. 12, Cupboard. No. 13, Sink. No. 14, Buttery, 7 by 12 feet, having a cool part of the house, as it is or the north side, the house fronting the east. No. 15, Back kitchen. No. 16, Meal-room. No. 17, Wood shed. No. 18, Walk. No. 19, Shed and barn. No. 20, Waste room for setting away cooking utensils. *Second Story.*—No. 1, Sleeping room, warmed by kitchen stove-pipe. No. 2, Chimney and closet. No. 3, Sleeping room; (Nos. 1 and 3, 14 by 15 feet, with fire-place or stove.) No. 4, Small room, lighted from hall. No. 5, Hall, a large room for spinning and weaving, or for beds; size 15 by 28 feet, or it may be divided by partition. No. 6, Bed-room or closet, lighted from hall; stove in the hall.

Thus I think you will perceive by this arrangement, at least one advantage—that the greatest possible amount of room inside is secured, in proportion to the dimensions of the building. I would also invite the attention of farmers to the materials of which the house is built, as affording for cheapness, strength, and durability, as well as security from the effects of dampness and cold, the best now in use to my knowledge. You will notice this building fronts upon a road running north and south. The road being changed will somewhat affect the position of the rooms.

I suppose the first object to be attained by procuring a model of a farm-house, is in the plan of the lower part or basement story; of course the dimensions may be lessened or increased, and each builder will use his own discretion as to size as well as heighth of his dwelling. My house is one story and a half, so the proportions of the upper rooms are somewhat curtailed by the slope of the roof: this may be remedied by building a little higher, if thought an inconvenience.

The doors are marked in Fig. No. 34, thus (⁏)—the windows are marked thus (·). Fig. No. 34, presents a ground plan of the house, and Fig. No. 35, the front side and south end. 24 light windows in the basement story, and 20 lights in the upper story.

[Fig. No. 35.]



Of the back kitchen, I have given but a loose description, as its size will of course be determined by the necessities of each proprietor. Very respectfully yours,
WILLIAM VERBACK.

Efficacy of Lime in preventing Insect depredations—Mildew of the Gooseberry.

Mr. Buel—Sir—Although not a tiller of the soil, I have lately become a subscriber to your valuable paper, and feel a disposition to perform what little may be in my power, to increase the stock of agricultural knowledge, and to stimulate to renewed exertions those who are practically engaged in this all important, though still too much neglected source of national wealth and greatness. In the Cultivator for May, page 57, I observed a communication, which stated among other things, that a piece of corn on ground where fragments of wall, &c. had been strewn for manure, was exempt from the ravages of worms. This recalled to my recollection some facts which were communicated to me in conversation some time ago, by an intelligent old gentleman, who was for many years a farmer in Columbia county, in this state, and which were in substance as follows:—He once applied what he supposed at the time was plaster or gypsum, but which was afterwards ascertained to be lime, to a number of hills of corn, potatoes, cucumbers, melons, &c. It was applied at the time of planting, about a handful being thrown directly over the seeds in each hill, previous to their being covered with earth. He remarked that the corn to which this application had been made, was entirely exempt from worms, while other pieces of corn in the vicinity suffered severely from their depredations. The cucumber and melon vines, &c. were also exempt from their attacks, neither were they troubled by the striped bugs or flies, with which they are generally molested. The gentleman assured me, that he had afterwards repeated this experiment a number of times, and always with a like satisfactory result. It would seem from this, that lime is to a great extent a preventive of the ravages of the grub and other insects, when applied at or previous to the time of planting. The mode practised by my informant, may not answer for all soils and situations, but the same result might probably be attained by throwing the lime mixed with earth over the surface, and ploughing or harrowing it under previous to planting.*

A short time since, at the house of a friend, while overlooking a volume of the Cultivator, (for 1835,) I noticed a communication in which hydraulic or water lime, (some account of which was given in a recent number,) is highly recommended as a paint for fences, out-buildings, &c. The writer asserts that it is more durable and much superior in all respects to common lime. With the exception of stating that he mixed it with skim milk, he gives scarcely any directions respecting the proper manner of applying it. I shall be pleased if some of your correspondents, who have used the water lime for such purposes, will communicate the result of their experience, and if favorable, state the best method of mixing and preparing it, &c.

There are, in my garden, some young gooseberry bushes, which have been well manured and pruned, but the fruit, since they commenced bearing, (about three years ago,) has been uniformly *rusty*, as it is commonly termed. To prevent this, I have tried several remedies without success. Last year, seeing salt dissolved in water somewhere recommended, I had it sprinkled over the bushes several times, commencing when they were in blossom, but without any effect. I have also tried lime, (recommended I believe in the Cultivator.) Last fall, it was applied freely about the roots, and the branches whitewashed as thoroughly as practicable, and a small quantity mixed with water was sprinkled over the bushes two or three times this spring. This experiment answered no better than the other. It would be a source of gratification to me, and doubtless also to many other persons, to be informed of any effectual remedy for this disease, which may be known to you or any of your numerous correspondents. Respectfully yours,
E.

New Utrecht, L. I. July 18, 1839.

Remark.—We have cultivated the gooseberry eighteen years—during sixteen of which, we lost most or all of the crop by mildew or rust;—but the last two years the fruit has been fine, clean and healthy. We impute the recent exemption to the application of brine (salt and water,) to the ground about the bushes in the month of February, which we have done two years. We consider the mildew a vegetable parasite, which abides permanently upon the collar and root of the bush, and from which seeds are disseminated, under a suitable state of the atmosphere, in summer, to the fruit; and that the application of salt, when vegetation is dormant, destroys the parasite without hurting the bush. Pickle may be used in the growing season, at the rate of one ounce of salt to one gallon of water. In winter it may be made much stronger.—*Cond.*

Crosses of Vegetables.

Deep River, Ct. 16th July, 1839.

J. Buel, Esq.—Sir—Will you answer me, in the Cultivator, the following questions, giving either your own opinion, or that of correspondents? I think the English writers and some others are not correct on that subject.

1. What kinds of vegetable, vine or plant, will cross or mix, so as to produce a good or bad kind?
2. Will any that does not produce a kind between the two, injure each other in this way?
3. Are not many of our seeds injured in this way, producing worthless plants among good crops?
4. Will not the potatoe bulb or root, be injured in the blow, crossing without making use of the seed?
5. Will not perennials and annuals sometimes mix together in the blow?
6. Will the cucumber and melon—the muskmelon and watermelon, or the melon and squash, mix so as to inure the seed?
7. Will not all of them in their own kind, mix or cross so as to produce good or bad fruit or roots? Yours truly,

PHINEAS PRATT.

ANSWERS.

1 and 2. Vegetables, like animals, will mix and produce

---

* If lime is a preventive, it must be owing to its caustic quality, and should of course be applied in a fresh burnt state; and it would seem better, as a guard against the cut-worm, to apply it on the surface, after the seed is covered. The soil about the young plant then becomes saturated with the alkali, which must be obnoxious to the grub. We have applied both ashes and lime in this way to our corn; and although the crop sustained no injury from the worm, we cannot exactly say that the lime and ashes saved the corn.—*Cond. Cult*

new varieties, through their seminal organs, or seed vessels, if they are of the same genera, or varieties of the same species; and the progeny, as in animals, will be like the parents, good or bad, better or worse than the female, according to the quality of the male, which impregnates or fecundates the female sexual organ.

3. Many of our field and garden seeds are greatly deteriorated in this way. Hence, among gardeners, no two kinds of cabbage, or of turnip, &c. are allowed to seed near each other, lest they should change the variety desired to be preserved pure; hence florists destroy single and imperfect flowers, lest they should fecundate and spoil the seed for double flowers; and hence, too, our field seeds deteriorate, under careless husbandry, until they become in a manner worthless.

4. The potato will mix, like other plants, through the blossom and ball, but not through the tuber; that is, the seed of the ball will produce new varieties, but the tubers will not.

5. We think perennials and annuals will not mix, though of the same genera.

6. Different species and varieties of the cucumber, melon and squash will mix with some of their own genera, but not with another genera, and not with all of their own; as, for instance, we doubt if the seed of the muskmelon is affected by the contiguous growth of the cucumber; or the seed of the watermelon by the contiguous growth of the squash, though the two first belong to the *cucumis*, and the two latter to the *cucurbita* family. Again—the egg plant, tomato and potato belong to the genera *solamum*, yet we do not think the blossoms of the one affects the seeds of the other.—*Conductor.*

Poudrette Manure.

Mr. J. Buel—Dear Sir—I purchased last spring, a few bushels of this article, which I applied to corn and potatoes; making experiments of different quantities to the hill, in order to test its strength more fully. The experiments have resulted favorably—one hand full or a gill, being sufficient in the hill to cause either corn or potatoes to vegetate sooner, and outgrow what was planted at the same time on other manure. It has also been tried in this county on wheat, and I am informed that it answers an excellent purpose. I believe it to be *more fertilizing*, and at the same time *cheaper*, than any other manure used in the vicinity of New-York. It may be put up in barrels, and sent to any part of the country.

"*The New-York Urate and Poudrette Company,*" by whom it is prepared, is located on the Hackensack river, New-Jersey, having an office in New-York city, where orders are received.

JOHN G. BERGEN.

Brooklyn, Kings co. July 18, 1839.

Underdraining with Pine Gutters.

Southampton, Va. July 8, 1839.

Judge Buel—Sir—I get good information from some of your correspondents; and what little I know about underdraining, your correspondents shall be welcome to, if you think it worth publishing.

About six or seven years ago, I put down an underdrain in the following way:—In the first place, I cut a ditch the width of the spade, deep enough to make the land dry, and was careful to make it well. I then sawed blocks off of logs, about eight inches long, and rived them three or four inches wide and one inch thick, and lay these pieces across the ditch, about five or six feet apart, and settled them level with the bottom of the ditch. I then went to our piney old fields, where we have a plenty of pine poles, and cut those down about eight inches through, and dug them out in gutters; the poles may be from 12 to 18 feet long. After I got a sufficient number of these gutters dug out, I hauled them to the ditch, and commenced at the upper end of the ditch, and laid the first down, the big end of the pole at the upper end of the ditch, and the second pole was to lap on the little end of the first, and so on, until I finished. After all the poles were down, I hauled pine straw or pine brush, and filled the ditch about half full, and then returned the dirt, and the ditch was done forever. Since I put down the first drain, I have put down about 900 yards, and if I live, I intend to put down in the same way, all the ditching I shall make the balance of my life time. The durability depends upon how long the gutters will last; but as the air cannot get to them, I believe they will last 50, or perhaps 100 years. Yours, &c.

JESSE LANKFORD.

N. B. The big end of one pole is to lap six or eight inches over the small end of the other.

Bloody Murrain.

Judge Buel—Sir—Under this head I find in your last (July) Cultivator, a piece written by A H. F. Payne, (who appears to be a resident of the state of Missouri,) on his experience of the bloody murrain in cattle. As he appears to be unacquainted with the disease and its preventive, I am induced, from a long experience, to endeavor to throw some light upon that subject, for the benefit of those living in countries subject to that fatal disease, which I believe all new countries are subject to, while their cattle run at large through the summer season.

1. I hold that one ounce of prevention is worth a pound of cure.

2. I have found that wood ashes given in equal parts with salt, at the usual times of giving my cattle salt, for the last twenty years, has been a certain preventive.—This is my remedy—try it, Mr. Payne.

3. The bloody murrain is occasioned by an extended and overflowing gall, affecting the liver, causing the leeches or blood-suckers therein, and the flow of blood outward or inward, and death follows. Many other prescriptions might be given for reducing the gall, but I know of nothing so handy and cheap as to mix ashes with salt. Cattle themselves apply the remedy when they can come at lye made of wood ashes.

4. As the disease prevails more in new countries than old, and vastly more with cattle that run in the woods than with those in enclosed pastures, I infer that the woods herbage induces these extended galls to a ruinous extent. As the gall is some time in accumulating, it will be some time in diminishing; by this course, therefore, no person should trust a few messes in a season, or a cure when the liver is rotten. The working ox, the milch cow, the young and the old, the fat and the lean, I have had and seen die with the murrain, but all had extended galls that I ever examined; and perhaps no country has been more afflicted with this disease than the Western Reserve, in the state of Ohio, of which I have been a resident for thirty-five years, and am a practical farmer, and have not lost a creature with the murrain for the last eighteen or twenty years. Although I have now no occasion to let my cattle run in the woods, I still continue to use ashes with salt, fearing the result of neglect, having formerly lost many cattle.

I am sorry to hear that Mr. Payne is paying $5 per bushel for Baden corn, and that all a cheat. I think in his climate, the good yellow flint and perhaps red cob would do just as well; but he probably thought that when men had been detected in selling wooden pork hams, neatly canvassed, wooden nutmegs, and mullein for tobacco seed, &c. that the rogues had done cheating. Most respectfully yours,

JONATHAN WARNER.

Ashtabula co. Ohio, July 15, 1839.

Hon. J. Buel—Dear Sir—Judge Warner, the writer of the above article, is a practical farmer, residing in this place, and a man who has had many years experience in horticulture, and I hope you will give his article a place in your valuable paper. Very respectfully,

S. M'INTYRE, P. M.

Force of Prejudice—Utility of Premiums.

> "Men are fond of certain tenets, upon no other evidence but respect and custom; and think they must maintain them, or all is gone. Though they have never examined the ground they stand on, nor have ever made them out to themselves, or can make them out to others."—*Locke.*

This remark is applicable not to the understanding alone, but to the continual practice of men in their every day pursuits. No occupation is exempt from it, and upon none does this blind servility of the mind exercise a wider or more pernicious influence than upon agriculture.

Farmers generally are proverbial for prejudice, and an obstinate adherence to old fashioned and long tried methods of doing every thing; and nothing but the example of others, making the results of their innovations palpably and undeniably beneficial, will ever effect a change. This disinclination to change, or to adopt "new fangled notions," as they are frequently termed, arises from several causes; foremost of which may be considered the situation of farmers, retired, and beyond the influence of public spirit, and that enterprise and energy of character which impels others to improvement. Secondly, the want of means or capital to risk any deviation from a long tried course, without the certainty of remuneration. And, lastly, ignorance, the foster mother of prejudice and conceit, handed down from one generation to another, nursing itself in its own blind self-sufficiency, and effectually excluding the light which science, reason and philanthropy are struggling to disseminate for the benefit of others.

It is, however, cause of gratification, that the attention of farmers has at length, in some measure, been aroused, and that they are beginning to shake off the apathy that has so long enchained them. For the last three years, in many parts of our land, there has been a steadily increasing, and permanent improvement in the art, which, considering the small amount of light diffused, and the strength of prejudice opposed to it, has scarcely a parallel in the annals of agriculture. It is true, in parts of the old world, the products of the soil have been increased to a most wonderful degree; yet the improvement has been more gradual and limited in its extent; confined to certain districts or counties, where intelligence, united with ample means for experiment, guided the large proprietors in their endeavors to improve their unproductive estates. In this country there has been no stimulus of that kind to arouse the energies or to excite the ambition of the humble cultivators of the soil; content to live from hand to mouth, earning a mere subsistence, our farmers have groped along in the same beaten track, for the last fifty years. But light at last is beginning to dawn upon their benighted faculties. The press—that powerful instrument of good or ill—is insinuating itself into every hamlet and cottage. Rail-roads and steam-boats have raised, as by an enchanter's wand, fertile valleys and pretty villages from the deep seclusion of remote distance, to the admiring eyes of men of taste and science from the city. Intelligence and capital are at work in the country, developing its capabilities, and adding interest and beauty to its natural charms. Science has invaded the territories of ignorance and simplicity, and lo! the change.

Yet the struggle has but commenced; although in many favored parts, the genius of improvement has alighted in her course, still there is a vast extent of territory where the obstinacy of habit, and blind adoration of ancient customs, are still to be combatted and overcome. How this is most readily to be effected, is yet a matter of question; in the great work of reformation and improvement, our agricultural papers are certainly, so far, entitled to the largest share of merit; but their influence has been mostly confined to the upper class of farmers—men of intelligence and property, who expect to realize a certain percentage for their investments; which, failing to obtain in the ordinary methods of cultivation, they seize with avidity upon any thing which promises better; and partial success prompts to further experiment. With these, prudence and a just economy are all that is necessary. Once excite the energies of an intelligent mind—let it be interested in the occupation before it, and its course must be onward. The field of agriculture is the field of science, and the further we advance in it, the brighter and more interesting are the charms unfolded to our view.

It is the poorer, and by far the larger class of farmers, for whom the sympathies of the more enlightened should be enlisted. Their improvement offers a wide field to the philanthropist and patriot also; for as they excel in numbers, so also must their efforts affect the general prosperity of our common country. But their numbers exclude the possibility of individual exertions in their behalf. By furnishing them with cheap publications, or giving them access to works of science which they can comprehend, we may certainly benefit a few, but the great mass must be operated upon in a different manner; with them, the value of any instruction cannot be appreciated, unless its connection with material improvement be distinctly shown. They must be spoken to in the language of dollars and cents, and this can only be afforded by legislative bounty, in the shape of premiums, for excelling in the different branches of their business. Tell a man who has been accustomed to get his stock through the winter, by feeding them the refuse and unmarketable forage from his hay or grain crops, that it would be better to devote time and labor to the cultivation of roots for the same purpose, and he cannot comprehend you; nor will he, so long as he does not clearly see the advantage; but urge him to the attempt by offering a sufficient inducement, in the shape of a premium for any particular crop, and when it is once grown, it must be either fed or sold. In either case it acts beneficially; for it must be obvious to the dullest mind, that what will remunerate the purchaser, certainly must the producer, if consumed in the like manner.

The same argument holds good with stock, and all the various products of the farm. Offer sufficient inducement to raise none but the best, and the poor will speedily disappear. And why should it not be so?—Can our legislators, who have frowned down every effort to extract but a pittance for this noble purpose, offer one plausible reason for withholding it? Can they be so wilfully blind as to refuse to see its benefits, or so wanting in patriotism as to deny but a small amount for a public good, when they unhesitatingly lavish thousands for the enrichment of the few, who openly speculate upon the property of that public? If so, then upon them should be cast the reproach which now attaches itself to the low state of agriculture in our country.—And let those who now feel the reproach, manifest their indignation in the proper place, and when the proper time arrives.

Our farmers are justly termed the bone and sinew of our country. It is high time for them to show the strength of the material they are made of. Let their voices speak from the ballot box—let them discard all party distinctions, and look only to the integrity and honesty of their candidate, and let him be one who has shown, by his exertions in their behalf, that he has his country's good at heart.

Experiments with Poudrette.

Narrows, L. I. July 23, 1839.

Mr. Buel—Having procured a few bushels of poudrette from the New-York Urate and Poudrette company, who are extensively engaged in its manufacture, for the purpose of making experiments to test its efficacy, I will give the results as far as present appearances indicate, for insertion in your valuable journal, if you deem them worthy of a notice.

A compost was made by mixing the article in question with city-stable and hog manure, in such proportions as to make the cost of a bushel of the mixture double that of the same volume of the stable and hog manure. This compost was used for cucumbers, melons and corn; putting the usual quantity in the hills in some rows, and in others less: in the growth of the vines of the two first and yield of the cucumbers, I find nothing to warrant a belief of sufficient advantage to compensate for the extra expense; but the corn, when it came up, was of a darker green, grew more rapidly, and still holds the ascendency over the adjoining rows, which were manured in the usual manner. Two rows of corn adjoining the others were also manured with half a pint, and two rows with a pint in a hill of the poudrette alone, covering it with soil previous to dropping the seed; for I find by experience that corn does not prosper when planted in contact with hot fermenting manure: in the growth of these rows there is but little difference; those containing the largest quantity excelling; but they all flourish more than any others in the field, and are also superior to those in which the compost was used. A pint of poudrette mixed with the soil in each hill, was applied to two rows of cucumbers; these appear to grow and yield about as well as the adjoining rows, in which the ordinary manure was used.

Also planted in May on clover sod, in rows, a small piece of Mercer and kidney potatoes with good stable manure, a large shovel full on four potatoes; each tuber being 15 inches apart, excepting a row of each kind in which a half pint of poudrette alone was dropped on each potato: those last vegetated sooner, and the vines are stouter and more thrifty than the others.

From all appearances, the yield of the corn and potatoes on which poudrette alone has been used, will exceed the others; but the final result I intend accurately to ascertain and communicate to you when the crops are gathered in the fall.

My object in writing this communication, is to draw the attention of agriculturists to this kind of manure; which, without doubt, when properly applied, will prove as in France, China, and other countries, a valuable auxiliary to the farmer; and I hope that those who are better qualified many be induced to take the matter in hand and enlighten the public, so that the most judicious modes of application for the different crops and varieties of soil may become known. The conversion of a substance into a valuable manure, which in large cities for ages has been consigned to the river or otherwise dissipated and lost, and which increases the productions of the soil, and assists in making our land teem with plenty, must prove beneficial, not only to farmers, but to the whole community. Especially to the farmers in the vicinity of New-York will it prove to be of great benefit; for they possess not the unexhausted soil of the west to operate upon; they are compelled to fertilize their land or starve; to pay thousands of dollars for the sweepings of the streets and emptyings of the stables, of which in consequence of the increased demand and facilities of transportation, it is difficult even to obtain a sufficiency, although the price has nearly doubled in the last 20 years.

There may be some failures in the experiments made with this kind of manure, before the most judicious modes of application are ascertained; yet its final triumph and ultimate success may with safety be predicted. Yours, TUNIS G. BERGEN.

The above communication was submitted to Mr. Peter Barthelemy, who is one of the discoverers of the process of making urate and poudrette, and who is the only introducer of the article in the United States, and who joined the present company for the purpose of manufacturing urate, has made the following remarks:

"It will not answer to make a compost of poudrette with any other *manure*. It must be applied to the earth or soil as delivered from the factory: because the poudrette will act immediately upon the compost added to it instead of the vegetable matter in the soil; and the consequence is, its effect upon vegetation will be retarded, as long time as it will require to have the other part of the compost absorbed, and the additional compost will be lost to the vegetation; the poudrette being of a stronger nature will first absorb any other manure before fertilizing the crop; in other words, poudrette alone is worth more than all the additional compost manure added to it. P. BARTHELEMY."

The Wheat Fly

Is an animal that has never attacked my grain. It has so happened that my neighbor's wheat and mine were in adjoining fields, separated only by a fence; that his wheat was nearly destroyed by the fly, and not one discovered in mine. The only solution I can give to it is as follows:

My wheat *is uniformly* sowed late, never until there has been a hard frost,—sufficiently so as to kill insects of that kind. I cause a strong solution of salt and water to be made, sufficiently so to bear an egg; and my wheat is soaked about 24 hours in it, and then rolled in lime on the barn floor. When that rule has been followed, my crops have been about as good as my neighbors, when their wheat *was not affected* with the fly.* Great care should be taken not to soak the wheat more than about 24 hours, and then rolled in lime; else the germinating quality of the wheat may be destroyed or injured. A. DEY.

New-York, 23 *July*, 1839.

How to increase the circulation of Agricultural Papers—Subscribers' Duties.

Lake C. H. Ia. July 18, 1839.

My Friend—This is to you—I see you about to pass over and not read this article—you don't like the title! It an't interesting to you, do you say? Look again—look at the signature,—did you ever see my name to an article in this paper that did not interest you? There now, you see I am an old acquaintance. No. Well, then you did not take the last volume of the Cultivator. The more's the pity. Thousands who read that, will remember me right well. They will expect something interesting as soon as they see this article is from their old friend. I beg of them, as well as of the publisher, a thousand pardons that I have neglected them so long. My conscience has not been easy for months. I knew I had not done my duty. For when a man, particularly a friend to agricultural improvement, knows that he has a talent to be useful and interesting in his writing; that by a little light labor of his pen, that he can lighten the labor of his fellow laborers, he *neglects his duty* if he neglects to do it. You need not call me an egotist, because I say that I know I have that faculty. Thousands have told me so; and I now here tell you that I have neglected my duty. Reader, have you neglected yours? did you write a letter to your paper, and because it was not published, say you would never write another? Did you say further, that you would never subscribe for the paper again? Shame on you then,—Oh! you was only angry a few minutes,—you're over it now, and think yours the best paper in the world. You think you made an hundred dollars more off of your farm last year in consequence of taking it. So do I. I'll tell you another thing that I think. I think that the readers of the Albany Cultivator alone, made $50,000 more in their various occupations last year in consequence of reading it; and equally so of the New-England Farmer,—The Genesee Farmer,—the Franklin Farmer,—the American Farmer, and so on of every good farmer's paper, in just proportion. There is another thing I think; that the increased value of those readers' farms is twenty times the above sum. There is another thing I think; think, why, I know it. I know it by my own feelings. I know that the increased happiness of those readers was worth twenty times more than all the increase of property. Suppose then that the circulation was doubled,—yes, but don't every body subscribe that wants to, now? No, not half. But you can get them to—and it is *your duty* to do it; you an't able to pay for any papers to give any. Who asked you to do it? There is your neighbor Jones that always is reading yours when he can get a chance, and who never has a dollar that he thinks he can spare to pay the subscription; would be glad to take the paper and pay you in chopping wood. Now do you think you did your duty last year? you know you had a two dollar bill, and it cost you some trouble to get it changed when you sent for yours; you might just as well have sent for two copies and let Jones have had one. He would'nt have lost them two fine old sheep if he had read the Cultivator; because he would have seen that ruta bagas were just what they wanted. But poor man; did'nt know it. There is your neighbor Williams too; you had some dealings with him, and he would have been glad to have taken the paper from you, "in the way of trade;" "because that would not be paying out money," though you paid it to him. Now you know that he lost nearly all his first planting of corn by the insects, birds, &c.; and then came up to your house to "get the receipt out of the paper how to doctor the seed." But then it was too late to replant; so he planted beans. Did you ever see a finer crop? Got nicely ripe and pulled and hung up on the scattering corn, lugged out to the fence, and stone heaps, &c. to put up to dry. Well, there came on a long warm rain; and poor man, he lost the whole of them nearly, more than an hundred bushels. Do you remember when he came to your barn, and the conversation? "Did'nt you lose your beans, neighbor Thomas, that warm rain?" says he in perfect astonishment, "I saw you pulling them the same day I did,—and mine were the ripest. Why bless me, how bright they do thrash out. Now in God's name, do tell me how you saved them?"

"Why, I read it in the Cultivator more than a year ago."

"Good heavens, 'twould have been worth more than an hundred dollars to me."

"So it was to me—and then it's so easy and simple; take a parcel of stakes,—I took old bean poles out of the garden,—out into the field and stick 'em round, and put a few stones or sticks at the bottom, and then pull the beans: no matter how green they are, and stack them up with the roots touching the stalkes until you get high enough; and then tie the top course with a little straw or a string, and the trouble is all over; they will cure as well as a shock of corn, and injure less."

"Well now, I have always intended to take that paper,—but I never had a dollar to spare at the right time to send for it." Now my friend, do you think you did your duty? If you had, would you not have sent for a paper for each of these neighbors, and in a manner compelled them to take them?

I got five and twenty into circulation "in the way of trade;" can't you? don't be mistaken,—I mean YOU.—Can't you get one; just one more subscriber; it is *your duty*. Nothing can sustain this government but an improvement in her agricultural branches. I don't know how many hundred millions of dollars we are in debt. We? Yes, WE. You and I, and every *producer* in the government. On that debt annual interest must be paid. Must be paid by a tax on agriculture. Let it be mystified as much as it may, 'tis the only way whereby under heaven that it can be paid. 'Tis the farmer that pays for every rail-road and canal, whether useful or not; and when farmers are so much in debt, it is time they were improving the means to get out. How can they improve without they gain knowledge? How can they gain knowledge unless they read? How can they read unless they are provided with papers or books. How can some of your neighbors provide themselves, unless you assist them? Then for once attend to this SOLEMN DUTY. Don't let your conscience rest one day, until you have procured one more subscriber to this paper. And if you can't procure a subscriber, send yourself and procure another set, (20 if you are able,) and distribute them among your neighbors; you will soon see the leaven work; the corn will come up, the beans will be saved, and you will rejoice at the end of the year, as you think to yourself, "how much good I have done with so small a sum." And here I make you a proposition. At the end of the year if you are dissatisfied that you have followed my advice, write to the publisher and your money shall be refunded to you. He will endorse this proposition for me I guess.

And this reminds me, the last of my "extra" numbers is used up "in the way of trade;" add another to my list, I must keep one on hand; 'tis *my duty*; 'tis the way I make up my list of subscribers—and it is certainly a large list for a place so new, where all are poor and new beginners in life.

But the effects are visible. There are no "Nick Bradshaw's" in this settlement.

There are some other duties that "we owe one another," but my letter is already too long. I shall write again. In the mean time think of the *duties* here pointed out. Can you deny them to be truly stated? Then instead of thinking, be up and doing; and truly you shall meet your reward. Most truly your agricultural friend, SOLON ROBINSON.

Holbrook's Revolving Horse Rake.

Whitesboro, July 20, 1839.

Jesse Buel Esq.—Dear Sir—I have used the revolving rake of Holbrook & Co. on my meadows for six or seven years past; and am confident that a man and horse can rake more than ten men with the common rake.

Mr. Holbrook's rake is superior to any I have seen; and I confidently recommend it as better than any horse rake now in use. Respectfully your friend and obedient servant, S. NEWTON DEXTER.

Remark.—We have received, but have not yet been able to use, one of Mr. Holbrook's rakes. Our grass is generally too heavy for a horse rake—two rakings by hand serving for a tolerable winrow; and our habit of making our hay in grass cocks superseding spreading the hay. They are for sale at W. Thorburn's, Albany.—*Cond.*

Principles the bases of correct Practice—A Proposition.

Stockport, 7th mo. 1st. 1839.

Respected Friend J. Buel—I have long been a reader of the Cultivator, and have derived from its pages a great deal of pleasure and a great deal of substantial benefit. I commenced farming without any previous acquaintance with the business; hence the large body of sound practical information contained in it, has been peculiarly valuable to me. I have, however, regretted that so many of the dicta advanced by thy correspondents are based on the narrow foundation of a single experiment.

It is unfortunate for the progress of the *science* of agriculture, that this habit of theorising on the basis of a single experiment has become so inveterate with our rural population; it seems to me that among other evils resulting from it, is the strong distaste for *book farming* which is manifested by so many farmers.

They find in one treatise, that the phases of the moon should be strictly attended to in all agricultural operations, because he has tried the experiment and found it to be so. Another author advises us to plough and sow whenever we are ready, without the slightest regard to lunar influence. He has tried the experiment and found that the moon had neither part nor lot in the matter.

This controversy respecting lunar influence, is very far from standing alone as an example of the contrariety of opinion existing among our most enlightened agriculturists; indeed, there is scarcely any single practice recommended by our agricultural writers but what a diametrically opposite practice is strongly enforced by another, and both appeal to *experiment* to support their respective opinions. The unsophisticated farmer, puzzled, and perhaps led astray by these conflicting opinions, imbibes the idea that experiments are very fallible things; and that book farming is only fit for those who have plenty of money to *lose*: hence, he either goes on in the old track of his fathers, or finding that guessing is far easier than experimenting, and that it leads to results quite as definite, forms a theory of his own, and does well or ill, according as it approximates to truth or error. Now in experiments conducted by those who know how to interrogate nature, there is none of this ambiguity; the results are as certain, and the general laws deducible from them, stand on as firm a foundation as any of the propositions of Euclid; those who have traced the masterly investigation of the nature of caloric by Dr. Black, which resulted in the discovery of latent heat,—or that of the properties of oxygen by Lavosier, which resulted in establishing the theory of combustion, will have no difficulty in asserting that the same skill and patience which were exhibited by these illustrious masters of the Baconian or inductive system of philosophy, be applied to the solution of any of the vexed questions in agriculture, the result would be equally satisfactory; and let me remark in passing, that I know of no way in which thou couldst employ thy gifted pen more profitably, than in giving a plain and simple abstract of the fundamental principles of Lord Bacon's celebrated system of inductive philosophy.

It is a disputed question amongst farmers, whether plaister ever benefits clay land,—as usual, there are plenty of experiments on both sides. I have frequently sown it on clays without the smallest perceptible benefit; but this spring, I was told to sow it at the time of full moon in April. I did so; and there is nearly twice as much grass as there was last year. This of course is conclusive that clay lands are *sometimes* benefitted by plaister; but it affords very little light on the far more important question, (under what circumstances is it beneficial to clay lands?) because I did not pay attention to any of the collateral circumstances.

---

* Our correspondent alludes to the *Hessian fly*, not to the *grain worm*; as the latter attacks the ear, and against which late autumn sowing would be no preventive; but rather aid in the work of destruction. The grain in the early sown might be too hard before the fly appeared; but that sown late comes into head in the nick of time for the deposites of the fly.—*Cond.*

I would here remark for the sake of precision, that the clay on which the experiment was tried was of a stiff, adhesive character; containing very little, if any, silicious matter. It contains about 90 per cent of alumina and 10 of vegetable and earthy matter. Now is the success of my experiment owing to my sowing at the time of full moon in April, or to the fact that it was sown early in the season, or to the wetness or dryness of the season immediately following, or to the absence of snow last winter. In order to test the question thoroughly, let eight individuals of leisure, and of moderate acquaintance with science, (one in each senate district) provide themselves with a thermometer and barometer and rain gauge. Let them also provide themselves with a book ruled for the purpose, and commencing on the first day of January next, note in it at 8 A. M., 1 P. M. and 8 P. M.; the state of the thermometer, barometer, and the direction of the wind and the state of the sky with reference to clearness and cloudiness; let the figure 0 represent entire clearness, and 10 entire cloudiness; if the sky is half covered with clouds and half clear, let it be represented by 5, &c.; and let them each day add a note respecting the general appearance of the weather, or any thing in nature affected by the weather. Whenever it rains, let them carefully note the number of inches and parts of an inch that has fallen; when it snows, let them be careful to select a level piece of ground sheltered from the wind, and measure its depth as soon after it has fallen as possible. As soon as the frost is off the ground, let a number of spaces, each one rod square, be marked off contiguous to each other; then as soon as the snow is off, let one rod square be sowed with one gill of plaister, and the square rod next to it which we will call No. 2, be left without any. At the time of new moon in April, let No. 3 be sown with one gill of plaister, and leave No. 4 without any. At the full moon sow No. 5, and leave No. 6; and so on, at the time of new and full moon in May and June; then let the grass on all the ground be cut in one day, and let the weight of each square be separately noted.

Care should be taken to weigh the hay on all the squares as nearly at the same time as possible, so that one may not be dried more than another; and that the quantity of plaister sown be accurately measured. Indeed, perfect accuracy in all the different steps which I have detailed is all-important. I should like to point out the points which I expect would be settled by the experiments, but my paper is already full, and I must close by saying that for the sake of uniformity, each experimenter should select stiff clay,—not black muck, nor heavy loam; but *clay*. Respectfully thy friend,

N. N. D.

REMARK.

A compliment of a bound volume of the Cultivator will be made to any gentleman in each or either of the eight districts, who will carry out the suggestion of our correspondent and send us the result.—*Cond.*

A Bird Story.

Milton, Ulster co. N. Y. July, 1839.

Friend Buel—I would not have ventured to forward the following statement, were it not that the narrator of it, Edward Hallock, of the firm of Wm. Hallock & Brother, of Milton, Ulster co. is known to thee, and known to be of unquestionable veracity. I have heard him before express his conviction, that if birds were protected and cherished by farmers and others, we should never be subjected to the loss of corn or other crops by grubs; and that other noxious insects would be sensibly diminished. There is a small kind of bird (the males nearly black, the females brown,) that is noted for being around and following cattle in the field, as in the case I am about to detail. Mr. H. says, "on the 26th of the present month, I was ploughing for turnips, myself with one team and my son with another; and observing that we were followed by a flock of the above little birds, I took it into my head to notice their motives, to ascertain what was the attraction, when I perceived that their object was grubs. We ploughed up plenty of a small white and a large brown or grey grub, as well as some in a chrysalis state, and angle worms; all of them, *excepting angle worms*, appeared to be acceptable to them; and as the sequel will show, they were capable of devouring large quantities. I should think that one would make way with at least 100 per day. I cautioned my son against making any motion towards noticing them, in any way to intimidate them; as I found they grew more and more bold in their honest avocation, and as the land diminished in width, they would remain in the opposite furrow when not more than three or four feet distant. At length my son spoke cautiously, and said there was one on his plough beam. I then stopped the teams and told the boy to pick up a grub and show it to the bird that had distinguished itself by its tameness. He did so; and the bird immediately seized it. Encouraged by this, I told him to pick up the next white one, and hold it out in his fingers near the ground, crawling down, he did so, and the bird came and picked it out of his fingers! Afterwards he stood up and held out one, and the bird lighted on his hand and picked out the worm. This was repeated until it lighted on my own hand; I raised it up and applied my cheek to its wing without frightening it away. The next day he was not slow in finding us, and practised the same familiarity, in presence of James Sherman, William Hallock and others of the neighbors; it came into the cornfield where the boys were weeding corn, and actually, without any special attraction, perched upon the head of one of the boys; it continued these visits until one of the boys in an adjoining field, could not repress his inclination to seize and hold it. This made him more wary, but he gradually recovered his confidence." I communicate these facts in the hope they may contribute to produce an examination into the subject of how far it would tend to the agricultural interests, to fall upon some method to tame and familiarize small birds, instead of frightening, maiming or destroying them.

Please to concoct something from the above; and from the fact of turkey buzzards being domesticated in Charleston and the southern cities for scavengers—also, that in some province of Germany a premium was offered for the extirpation of a kind of bird, and afterwards doubled to have them back again, on account of the insects destroying their wheat.

E. HULL.

EXTRACTS.

Of the Nature and Action of Manures.

CONCLUDED.

[*From Chaptal's Chemistry applied to Agriculture.*]

Besides the characteristic of providing plants with food, the various kinds of dung possess other qualities, which add to their fertilizing powers. Dung as it is applied to the ground, is never so much decomposed as to have ceased fermenting; and from the moment it is mixed with the soil it produces in it a degree of warmth favorable to vegetation, and serving to guard the young plants against the effects of those sudden returns of cold in the atmospheric temperature, which are so often experienced. On account of the viscous fluids which it contains, dung is not easily dried, unless it be in contact with the air. It therefore preserves the roots of the plants in a state of moisture; and supports vegetation at those periods, when without it, plants would perish from drought. It likewise contains many salts which are transmitted by water to plants, serving to animate and excite their functions. The various kinds of dung, mixed with earth, may be considered in the light of amendments to the soil; and in this view they ought to vary according to the nature of the earth to be improved. Compact soils require to be separted and warmed; they require, then, those manures which have been but slightly fermented, and that are the richest in salts.—Calcareous and light earths require oily manures, which decompose slowly, and can retain water for a long time, to furnish it to the wants of plants in the seasons of drought.

It is by separating these principles, that we may be able to appropriate the various kinds of manure to each species of soil and plant; the attention of agriculturists is already directed, upon this point, to the composition of mixtures of manures, called composts. These are formed by arranging, one above another, beds of different kinds of manure, taking care to correct the faults of one by the properties of another, in such a manner as to produce a mixture suited to the soil to be enriched by it.

For example, if it be required to form a compost for a clayey and compact soil; the first bed must be made of plaster, gravel, or mortar rubbish; the second, of the litter and excrements of horses, or sheep; the third of the sweepings of yards, paths, and barns, of lean marl, dry and calcareous; of mud deposited by rivers, of the fecal matter collected upon the farm, the remains of hay, straw, etc. and this in its turn must be covered with a laying of the same materials as the first. Fermentation will take place first in the beds of dung, and the liquor flowing from these will mingle with the materials of the other layers; when the mass exhibits the signs which I have pointed out, as indicating decomposition to be sufficiently advanced, it must be carried into the fields, care being first taken to mix well the substances composing the different layers.

If the compost be designed to manure a light, porous, and calcareous soil, it must be formed of materials of a very different character. In this case it is necessary that argillaceous principles should prevail; the substances must be compact, the dung of the least heating kind, and the fermentation continued, till the materials form a yielding and glutinous paste; the earths must be clayey, half baked, and pounded, or consisting of fat and argillaceous marl, and mud from the sea coast. Of these all the layers must be formed.

By following these principles in my operations, I have completely changed the nature of an ungrateful soil in the neighborhood of one of my manufactories. Over this soil, composed of calcareous earth and light sand, I spread, during several years, some calcined clayey earth; and this land, upon which I could formerly raise only stone fruit, has become adapted to fruit containing kernels; and produces excellent wheat, whereas before it bore only scanty crops of oats and rye.

Observations and researches in Agriculture:

BEING A FARMER'S LEGACY TO HIS SON.

[*From the Farmers' Monthly Visitor.*]

Prefatory Remarks.—The observations which we intend to make under this head are selected from a series of notes and hints which were noted down at the time of their occurrence, as likely to be of use to one of my family. I felt as if I were bound to make my son some wiser, some better informed for my having trod the path of life before him. I felt as if I should not comply with my conviction of duty if I did not endeavor to make the world, or at least my own family, some better for my having lived and thought before them. In accordance with this conviction of duty, I made, as leisure permitted, such memoranda as I thought may prove useful to those of my own family, especially, and perhaps to others through them; and from those of them which bear the nearest relation to agricultural pursuits, I have selected what follows. Perhaps they may prove to some young beginners in husbandry and rural economy what they were intended to be to him for whose use and reference they were principally recorded—a starting-post from the goal arrived at by a predecessor in the course.

1. *Ruta Baga:—advantages of this crop.*

You may sometimes be placed in circumstances like the following, in which you would hardly know what to do, were it not that the season for sowing ruta baga gives you some elbow-room. For instance; you may not be able to get out all your manure in season for your corn and potatoe crops, as a farmer's work in May generally comes thicker and faster than a month later.—Rather than summer your manure, or get it out at a great disadvantage at the season of corn-planting, plan your work so as to have a spot for Swedes to which you can apply your manure when you have more leisure to get it out.

When your wheat is winter-killed, or otherwise so injured as not to be worth harvesting, or when other crops fail, it is of advantage to have such a resource as the culture of ruta baga presents. You may cut your first crop of clover, if you cannot spare it as manure, and have your land ready early enough for this root crop.

Another advantage of this crop is the facility of harvesting it. A man can harvest fully twenty bushels of turnips for one of potatoes.

The chief advantage of this crop consists, at the present time, at least, in the much greater nett profit which may be produced from an acre in this than in almost any other crop. An average crop is six hundred bushels; but more than double this quantity is, on good authority, said to have been obtained. The expense of cultivation has been estimated as low as two cents a bushel; and I have never heard of judicious management being reckoned higher than four cents a bushel. As food for hogs, cattle, and even horses, three bushels of ruta baga are generally accounted of equal value with one of corn or two of oats. If you will be at the trouble of making the calculations of profit which these data furnish you, you will be astonished at the results. Take the average crop of hay at two tons to the acre, and the average crop of ruta bagas as above stated, and estimating three tons of turnips equal, for neat cattle, to one ton of hay, and you will arrive at a result almost equally surprising.

As a minor advantage I may mention, that on farms like mine which have not the advantage of a running stream where cattle can water themselves, and where we are obliged to break the ice or draw for them every time they drink—it is in such cases good for the comfort and well being of the cattle, and lessens our labor, that less water is needed when cattle are fed on this or other root crops. It is no small trouble to water cattle as they ought to be upon some farms in winter.

This crop possess other recommendations; these I shall not submit to you at present.

2. *Ruta baga.—Time of sowing, and quantity of seed.*

In latitude approaching to 42 and 43 deg. ruta bagas may be sown from the 10th of June to the 10th of July. I have always aimed at getting them in by the last week of June.

As to the quantity of seed, I am now well convinced, that it is much more profitable to sow more seed than is really needed than to be more sparing of seed, and be obliged to transplant. The time occupied in this operation will cost more than the extra seed saved. If you use only half a pound to an acre, you will have a good deal of transplanting to do; whereas if you put on four pounds to the acre you will have a great many to hoe or thin out, but with *regular* sowing, no transplanting.—Transplanted roots never do well. From eight inches to one foot should intervene between the plants.

3. *Soap.—A hint in housewifery.*

In summer and autumn your soap-grease is apt to accumulate beyond your immediate wants; if put away it is apt to be devoured by maggots, and if made into soap, you may not have pine or other appropiate vessels enough to hold it. Having suffered loss from being placed in such circumstances, we were much gratified with a piece of intelligence accidentally received, which relieved us from the disagreeable dilemma. By the boiling your soft soap with salt, about a quart of the latter to three gallons of the former, you can separate lye and water enough to make the soap hard. After boiling half an hour, turn it out into a tub to cool. Cut the cake which swims on the top into pieces, and having scraped off froth and other impurities, melt again, (without the lye and water underneath of course,) and pour into a box to cool. You may then cut it up into bars of proper dimensions for drying. By adding a proportion of resin, well pulverized, at the last boiling, you will have yellow soap like that made for market.

Families moving to the 'Far West' or otherwise, would find it more advantageous to make their soap fit for carriage in this way, than to give it away, or sell it for next to nothing.

4. *Starch from frozen potatoes.*

By accident or carelessness we once had a few potatoes left in the field so as to be injured by an unexpected frost. As we had not our supply of starch for the season yet prepared, it was thought best to take these potatoes, *before they thawed*, and obtain what starch we could from them. They did not yield so much as sound ones—perhaps a half.

5. *Causes of seeds not germinating.*

We have known, and heard of considerable loss and disappointment from seeds, particularly onion seeds, not growing. We have thought and inquired in reference to the cause, and the result of our cogitations and inquiries may be thus stated.

Without a certain degree of moisture, seeds will not germinate. On dry sandy soils, and in a dry season, it seems highly probably, then, that seeds may be deprived of the requisite degree of moisture: perhaps receiving just as much as will mould them and destroy their vitality, or being so near the surface as to be injured by the sun's heat and light.

But the seeds may have germinated, and have commenced to send out their roots and stem stalks and yet be destroyed. If the soil is not pressed closely to the seeds, and very dry weather occurs just at this period of the process of germination, the root being too distant from the soil, and too feeble to draw any supply of moisture, the liquid food of the plant contained in the fermented seed may be dried up, and the life thus destroyed.

If you would avoid disappointment and loss from seeds failing to grow, the preventive process is indicated by a knowledge of the causes most frequently productive of this result, which we think are those stated above. If you sprout your seeds before putting them into the ground you will preserve them from the first cause of failure, but if you pulverize your soil thoroughly and press it in this state with hoe, spade, or roller, upon the seeds thus sprouted, the root stem will soon and surely derive sufficient moisture from the soil.

In a few instances I have found my neighbors blaming the seed as useless, particularly of onions, carrots and parsnips, when I have obtained a little of the same seed, and found it to sprout quite well. You may easily save yourself from such reflections, or from the temptation to blame others, by steeping the suspected seed in warm or tepid water from six to twenty-fours hours, according to the size and hardness of the seed, and then setting it away in a warmish place for a day or two. If good it will sprout in this time; if kept warm in a darkish place, and it does not sprout in this time, the seed is faulty.

In connexion with this subject, I may state that several circumstances incline me to the belief that corn which has been sprouted—no matter in what steep—is safe from the ravages of the red or wire-worm. It has been fashionable to steep in a strong solution of copperas, and to ascribe the safety of the seed in this state, not to the change which fermentation has produced in the germ or chit which is usually first attacked, but to the change in the taste from the copperas. We have known corn soaked in simple water—in water alone—to escape from the attacks of the worm as well as that soaked in a copperas steep. Until this matter is made more certain, however, I would hold it bad husbandry to neglect the copperas, as in addition to the change produced by heat and moisture, we have also the disagreeable taste communicated by this salt.

6. *Stirring the earth a relief against drought,*

Is the title of a very excellent article published by the Hon. John Lowell, in the Massachusetts Agricultural Respository, from which you will find an extract in the text-book I first put into your hands—Fessenden's Complete Farmer. In a very dry season, such as we had in 1838, he had some early potatoes in a very sandy soil which seemed so feeble that they were on the point of withering daily. All hopes of a crop were abandoned; and therefore he though them the subject of what he then supposed a *desperate* experiment. He ploughed them thoroughly, and in three days, without a drop of rain, they were observed to have changed color, and to have started up afresh as if they had received the benefit of ample showers. A recollection of this experiment led us in the dry summer of '38, to compensate to our hoed crops for the want of showers, by keeping the earth well stirred and pulverized around them; and we are confident that our operations in this way were beneficial.

This need no longer be considered a *desperate* experiment, for science enables us to explain in what manner the benefit is produced, and might have indicated it as a proper course even before it had been tested by trial. In a time of drought take a piece of earth and pulverize the surface of one half of it, allowing the other half to remain in its hardened and baked condition. For several mornings afterwards observe upon which of these pieces the dew seems to remain the longest, or to have been imbibed the most. The piece which has been stirred will so evidently be seen to be the moistest, that no doubt can be entertained of your having gained some moisture for the soil in this way. Now it is universally or very generally admitted that the dews abound in the food of plants, and this being so, by stirring the soil around plants you furnish this nutriment to the roots by making the soil light and porous which conveys moisture more readily than a hard, baked soil. The air also is supposed to contain the food of plants in a gaseous or very readily-appropriated state. If this is so, and we have no reason to doubt, then it is easy to see that a light and porous soil is more permeable to the air and to whatever food it contains than a hardened soil can be. This consideration shows that stirring the earth may be beneficial not only in seasons of drought, but also at all times. And in confirmation of this, we recollect that it has been recorded of Curwen, an English agriculturist, that by continually stirring the soil around some field cabbages, he obtained them of the enormous weight of 50 lbs.

Mr. Lowell suggests another mode by which plants may be benefitted in a dry season, by stirring the surface, and keeping the soil light and porous. It is well known that porous bodies are bad conductors of heat. If you take a piece of woollen cloth or a little wool, and a piece of slate or metal, and place them upon a piece of lard or butter exposed to the rays of the sun, you will in a few minutes be convinced of the difference there is, as conductors of heat, between porous and compact bodies. Now it is reasonable to infer from our knowledge of this law, that earth in a hard and compact state must convey heat much deeper than soil that is loose and porous. And it is stated in confirmation of this, that compact earth will become very hot, while a light garden loam well stirred, will remain cool, at two inches under the surface, at noon of a sunshine day. Stirring the earth, therefore, not only allows more moisture and more food to be imbibed from the air and dews of night, but it also enables it to resist the heat of the sun's rays.

7. *How to make agricultural pursuits pleasant as well as profitable.*

For ages the employment of the husbandman has been looked upon as dull, uninteresting work. It has been thought to be a dull, plodding occupation of the hands and not of the head. And there has been too much foundation for such an impression. The agriculturists of years not long by-gone, did little with the head to dignify or enliven the work of the hands. A change for the better seems now near at hand. Perhaps in your day, farmers may be generally more intellectual, more intelligent, and more able to bring the truths of science to benefit them in their manual labors, and to give them interest and delight in their occupations. But whatever others do, I hope you at least will take such measures as will convince yourself, if not others, that agricultural employments are as interesting, intellectual, and pleasing pursuits as any with which they may be put in comparison. I know of no method by which you can more effectually render them so than by employing your mind upon your work. Most assuredly the more your mind is employed upon your work—in tracing effects to their causes, in accounting for failure and disappointment in understanding the operations of nature, in devising improvements, &c.—the more interest you will take in your employments and the pleasure and gratification you will derive from them. Moreover this is not only the way to make your pursuits pleasant, but it is the way to make them profitable also. Your mental operations must be wrong-sided and injudicious indeed if they do not lead you to the discovery of means whereby you can educe more produce out of any certain amount of labor and expenditure. The most intelligent farmers, you may easily convince yourself, if industry is not wanting, generally succeed in making their farms the most profitable. But what I wish especially to inculcate upon you, at this time, is, that you will feel more interest, more pleasure, more conscious dignity in your pursuits, the more you occupy your mind on the subject.

Agricultural schools would aid in thus elevating agriculture.

8. *The Horse—its management.*

Of gross and direct cruelty to your animals, I have no fears of your being guilty; but there are other cruelties which may pass under the milder name of neglect, against which I would warn you earnestly. For that man stands low in my estimation, who is careless of the comfort of his cattle, and especially of his companion and servant—the horse. I trust you will adopt the rule which I have endeavored to follow, as your maxim: I will treat my horse as I think I would like to be treated were I in his place! Allow me to drop you a few hints which may contribute to your accomplishment of this benevolent purpose.

When you purchase a horse, endeavor to find out how and upon what he has been kept—how he has been fed and otherwise managed. This it is important to ascertain, for you cannot make any *sudden* changes in the mode of management without discomfort to the animal, and the risk of injury. If a horse has been grained higher than you mean to, you must reduce the quantity of grain very gradually, and not, by any means, all at once. Again, when you take your horses from grass in the autumn, they should not have a totally dry diet all at once, but should be gradually accustomed to it by giving them roots and mashes with their hay. Begin likewise with a small quantity of oats, and gradually increase the quantity until you arrive at their wonted or intended allowance.

Feed your animals, your horses especially, as regularly as you feed yourself. Have certain hours of feeding, and do not deviate from these. Your horse, as well as yourself, will not feel so comfortable if feeding is postponed long after the usual hour.

Make no sudden changes, as I have said, in the quantity and quality of your horse's food, but at the same time accommodate the food to the exercise and fatigue which the horse has to undergo. Even if there is a rather sudden change in this respect, your change as to the quantity and quality of the food should be gradually accomplished. I am convinced, from errors and injudicious management in this respect, many diseases are entailed upon the horse.

All grain would prove more nutritive, if ground or chopped up. Some horses, however, chew up their oats much better than others. A good substitute for grinding the grain when that is inconvenient, is to mix with the grain a quantity of finely chopped straw. If the straw is coarsely chopped, you may probably find, as I have done, that your horse can pick up all the oats and yet leave a very considerable portion of the straw.

Let your horse be driven rather slow at starting, especially if just newly fed or watered. Increase his speed by degrees; and if warm, when within a mile or two of his journey's end, slacken his pace and let him cool down somewhat before being stabled. More anon.

T. C. A.

Clinton, Lenawee Co. Mich. June 22, 1839.

Massachusetts Premiums on Farms.

The Massachusetts State Agricultural society have offered premiums upon farm stock, to the amount of about $400, to be awarded at the Pittsfield and Worcester cattle show next autumn; and they have offered premiums to the amount of $600 for the best cultivated farms in the state. The queries to be propounded to the competitors, and to which they will be required to make answers, serve to indicate the points to be aimed at in good farming, and are therefore of general interest to all who seek to improve their practice; but independent of this, our subscribers in that state have a special claim upon us. We therefore copy from the New-England Farmer, so much of the publication of the trustees as relates to

THE BEST CULTIVATED FARMS.

The trustees again, with a hope of further awakening the attention of the farmers of Massachusetts to a sense of the importance of good cultivation, and at the same time of exciting an honorable competition for exhibiting the best cultivated farms, have decided to appropriate to this object *six hundred dollars* of the funds entrusted to them the present season, as follows:

For the best cultivated farm of not less than 70 acres exclusive of wood land, regard being had to the quantity of produce, the manner and expense of cultivation and the general appearance of the farm,	$200
For the next best,..................................	175
For the next best,..............	150
For the next best,.....	75

To obviate the objections which some claimants for premiums may have to making a written statement of the condition, products and management of their respective farms, as heretofore required, the trustees propose to relieve them of this trouble by an inspection, either personally or by an agent, of the farms which may be offered for premium.

The person or persons making the inspection, will require of the respective owners or occupants of farms, answers to the following inquiries:

Of how much land does your farm consist, exclusive of wood land?

What is the nature of your soil—does it consist of sand, gravel, clay, loam or peat?

If of a part or all of the above kinds, what do you consider the best method of improving them?

How many acres do you till, and how many cartloads of manure (meaning by cartloads 30 bushels at least,) do you generally put on an acre?

Is your manure applied in its long, or green state, or in compost?

Do you spread and plough in your manure put upon fields to be planted with corn or potatoes, or put it into the hills?

What is your method of ploughing and cultivating green sward?

How many acres of upland do you mow, and what is the average quantity of hay upon an acre?

How many acres of grass land do you irrigate; at what season and how long do you allow the water to flow your land, and what is the effect?

Do you manure the land irrigated, or any other land you mow, how much to an acre, and what kind of manure do you put on?

How many acres of low land, not suitable for the plough, do you mow, and what is the quality and quantity of the hay cut the present year?

What is your method of reclaiming low, bog or peat lands, and what has been your success?

How many acres of corn have you planted the present season; what was your mode of preparing the ground and the seed, the kind and quantity of manure used to an acre, the manner of applying it, and the quantity of corn raised to an acre?

How many acres did you plant with potatoes the present year; what was your method of planting, your manner of cultivating, and what the average quantity raised on an acre, and what kinds did you plant?

What number of acres of other vegetables did you plant, what kinds, and how many bushels of produce had you to the acre, and to what use shall you apply them?

How many acres of winter or spring grain did you sow the present year; how was the ground prepared; what quantity of seed did you sow on an acre? If you have raised wheat, of what kind; the nature of the soil, and was it sown with or without using lime?

How many acres have you laid down to grass the present season, at what time in the year did you sow it, how much seed to the acre, and was it sowed alone or with a grain crop?

What are your means and what your manner of collecting and making manure?

How many oxen, cows, young cattle, horses and sheep do you keep through the year? What is the size of your barn or barns, and have you a cellar under them; is your manure covered?

Are your cows of native, foreign or mixed breed?

What is your management of calves intended to be raised?

How much butter did you make this year, and how much cheese, and what proportion of it new milk?

How many swine did you keep, what quantity of pork did you make, and of what breed were your swine?

What do you feed them upon through the summer months and on what do you fatten them?

How many cartloads of manure do you take from your cow styes in a year, and of what materials is it made?

What number of hands is employed on your farm, and what do you pay for labor?

What is the number of your apple trees, and are they of natural or grafted fruits?

What number of fruit trees have you exclusive of apple trees?

Have your trees been attacked by canker worms or borers, and what is your method of destroying them?

In the cultivation of your farm, do you allow the use of ardent spirits?

The trustees are desirous that these questions should be answered with as much particularity as possible. The applicant will not, however, be required to answer them under oath, but according to the best of his knowledge and belief.

The trustees hope, and believe that by the method proposed, many important facts may be elicited, and the farming community enable to derive much useful information from the skill and experience of practical farmers.

N. B.—Claims to be addressed to Benjamin Guild, Esq. in Boston, before the first day of October next.

(Form of the Application.)

To Benjamin Guild, Esq., Boston:

Sir: The subscriber, living in the town of   , hereby makes known his intention of applying for a premium for the best farm, and offers the same for inspection.

On the Selection of Male Animals in the Breeding of Cattle and Sheep.

BY THE RIGHT HON. EARL SPENCER.

More from wishing to set an example to others, than from any hope that what I myself can suggest will be practically useful, I submit to the English Agricultural Society the results of my experience in an important part of that division of farming, to which my own attention has been particularly applied,—I mean the breeding of stock. The part to which the following observations apply is the selection of male animals. A large proportion of farmers breed sheep, and several breed cattle; to all who breed either, this subject is one of great importance.

The object of a certain number is to breed bulls or rams for the purpose of selling or letting them, but that of the majority is to breed oxen or wethers for the purpose of grazing. The first of these classes is very well aware of the importance of selecting good male animals, and profess to spare no trouble, and to be very indifferent as to the expense which they incur in obtaining them; but with respect to those whose object it is only to breed oxen or wethers, I am afraid the case is generally very different, and they take very little trouble and expend as little money as possible in procuring the male animals to which they put their females; that is, they consider as a matter of indifference that on which the profitable or unprofitable nature of their occupation mainly depends.

It is admitted by every one that the bodily and constitutional qualities of the offspring are usually similar to those of the parents, either combining in various proportions the qualities of both parents, or taking entirely after one. I should say, as respects cattle and sheep, that in most cases, the qualities of the male parent predominate in the offspring. I have also observed that the worse-bred the female is, the more will this be the case when she is put to a well-bred male. This observation was first made, I believe, by the late Mr. Berry, in an essay, for which he received a prize from the Highland Society. He accounted for it thus: a well-bred animal means one whose ancestors for several successive generations have all been good, that is, have all possessed the peculiarities in constitution and shape which it is the object of experienced graziers to obtain in their stock. The characteristic, therefore, of the family of such an animal will be such peculiarities; but the ancestors of a badly-bred animal will probably have varied in every possible way, and therefore there will be no distinguishing characteristic in its family; it is consequently most probable that the offspring produced from a cross between two animals so circumstanced will be more like the one in whose family there is a distinguishing characteristic, than the one in whose family no such characteristic exists. The common, but, I believe, mistaken notion, that the offspring from the first cross is better than that from any subsequent one, probably arises from the improvement in the first instance being so much more apparent than, for the reason given above, it is likely to be in any one generation afterwards. Now it is known to all graziers that the attempt to fatten an animal, who possesses no feeding propensities, produces loss instead of profit. If the above observations are correct, the feeding propensities descend from the sire; it is quite just, therefore, to say that a breeder of cattle or sheep, who considers it a matter of indifference what sort of male animal he uses, does consider it a matter of indifference whether he gains profit or incurs loss.

The first object which any breeder of cattle or sheep must keep in view, whether he intends to breed bulls or rams, or whether his aim is merely to breed oxen or wethers, is that the stock which he breeds shall be healthy. The first thing, therefore, to be considered in the selection of a male animal, are the indications by which it may be possible to form a judgment as to his constitution. In all animals a wide chest indicates strength of constitution, and there can be no doubt that this is the point of shape to which it is most material for any breeder to look in the selection either of a bull or a ram. In order to ascertain that the chest of these animals is wide, it is not sufficient to observe that they have wide bosoms, but the width which is perceived by looking at them in the front should be continued along the brisket, which ought to show great fulness in the part which is just under the elbows; it is also necessary that they should be what is called thick through the heart. Another indication of a good constitution is, that a male animal should have a masculine appearance; with this view a certain degree of coarseness is by no means objectionable, but this coarseness should not be such as would be likely to show itself in a castrated animal, because it thus might happen that the oxen or wethers produced from such a sire would be coarse also, which in them would be a fault. Another point to be attended to, not merely as an indication of a good constitution, but as a merit in itself, is that an animal should exhibit great muscular power, or rather that his muscles should be large. This is an usual accompaniment of strength of constitution, but it also shows that there will be a good proportionate mixture of lean and fat in the meat produced from the animal; the muscles being that part which in meat is lean. A thick neck is in both bulls and rams a proof of the muscles being large, and there can hardly be a greater fault in the shape of a male animal, of either sort, than his having a thin neck. I am inclined to say, that in the new Leicester breed of sheep, which is the breed to which I am accustomed, a ram's neck cannot be too thick. Other indications of muscle are more difficult to observe in sheep than in cattle. In a bull there ought to be a full muscle on each side of the back bone, just behind the top of the shoulderblades; he ought also to have the muscles on the outside of the thigh full, and extending down nearly to the hough. It will seldom happen that a bull having these indications will be found deficient in muscle. With respect to rams, my own observation does not enable me to point out any other indications of muscle except the thickness of the neck, which I have mentioned above; if other farmers are able to point out any, I would only say there is scarcely anything to which they ought to pay greater attention.

As I am writing for the use of farmers, it is quite unnecessary for me to attempt to give a description of what is considered a well-shaped bull or ram; it is also obviously impossible to express in words what is meant by good handling. It is sufficient to say, therefore, that no male animal is fit to be used at all as a sire whose handling is not good, and that the more perfect his shape is the better. The above observations apply to breeding generally; for whatever may be the sort or size of the animal intended to be produced, there is no doubt but that good health, propensity to fatten, and good shape, in all cases, ought to be aimed at. But there are not only different breeds, both of cattle and sheep, but experienced and very good farmers differ very much in opinion as to which peculiarities of shape and size are to be preferred, even among animals of the same breed. It is therefore very desirable, before any man commences to breed either cattle or sheep, that he should make up his mind as to the shape and qualities he wishes to obtain, and steadily pursue this object; if he does so, there is very little doubt but that he will succeed in having a herd of cattle or a flock of sheep possessing the characteristics which he at first intended they should possess; but if, on the other hand, he breeds at one time with the view of obtaining animals possessing one sort of shape, and at another time with the view of obtaining animals possessing a different sort of shape, the probability is, that his stock will possess neither the one nor the other in any degree of perfection. Having made this decision, he should take care that the individual male animal which he uses shall possess the qualities which he requires. In addition to this, it is of great importance that these qualities should have been characteristic of the family from which the animal is descended; and if he is old enough to have been the sire of any number of offspring, it is of a great deal more importance still that they should possess them. Because all the perfections of shape and quality which the best judge may wish to find in a male animal are, after all, only indications of what the stock got by him will probably be; the seeing, therefore, what they really are, is much more satisfactory.

There are few breeders, of cattle more especially, who breed upon so large a scale as to enable them to keep many male animals at the same time in use. A man, therefore, can usually only look at the general qualities of the females which he possesses, and observe what are the faults most prevalent among them; these he should be particularly careful to avoid in the male which he intends to use. It is sometimes said that a male animal ought to have no faults, and undoubtedly it would be very desirable that this should be the case; but, unfortunately, no such animal exists. All a man can do, therefore, is to avoid putting a male and female together whose imperfections are the same, so as not to increase the fault already existing in his stock. If a man breeds upon a large scale, and uses several males at the same time, he can, of course, attend to this more effectually than if he uses only one. In this case, he should select and put together the males and females individually, so as to endeavor to correct any imperfections which either of them show. Most breeders of sheep, indeed, do use more than one ram, and all who pretend to take any pains in improving their flock divide their ewes, so as to put them with the ram who will most probably effect this object. I need not say that those (some of whom, I am sorry to say, still exist) who turn two or three rams of different shapes and qualities into a field with all their ewes, without attempting to make any selection among them, have no right to expect to be successful breeders; and if they do expect it, will certainly be disappointed. I believe the general opinion of breeders is, that it is disadvantageous to endeavor to correct any fault in the shape of a female by putting a male to her who possesses, in extraordinary perfection, the merit in which she is deficient, but who in some other part of his shape is faulty. My experience leads me to say that this mode of endeavoring to correct a fault is frequently successful. It would be better that none of the females from which a man intends to breed should be faulty in shape to any considerable degree, but it almost always will happen that some animals, possessing an excellent constitution, good blood, and a great propensity to fatten, and therefore such as the owner would very unwillingly cull, will fail decidedly in some part of their shape. I would say that, when this is the case, it is worth while to try the experiment of putting to them a male remarkable for his perfection in this failing part; and, in my opinion, such a male will be more likely to correct the fault, than one who shows no one part of his shape very superior to the rest.—The late Mr. Cline, whose eminence as a surgeon is very well known, published a tract upon the breeding of domestic animals, which contained, as might be expected, most valuable information. His suggestions are such as ought to be very carefully attended to; but it is probable that his meaning has been mistaken in one recommendation which he gives, namely, that in which he is understood to say that it is always desirable that the male should be smaller than the female. When he makes this observation he is speaking of the crossing of different breed, and probably only means that in a cross between a large breed and a small one, the male should be taken from the small breed, and the female from the large one. It is hardly possible that he intended to say that in the same breed the male ought to be smaller than the female, because this is contrary to the practice of nature. In every description of land animal with which I am acquainted, the males are of a larger size than the females. The attempt also to follow this advice would undoubtedly, in a few generations, so very much reduce the size both of males and females, as considerably to diminish their value. I can say, from my own experience, that some of the best shaped animals which I have bred have been produced by following a contrary course. I prefer breeding from large females; but if I do breed from one which I think too small, I put to her the largest male of good shape that I possess. As one instance among several to prove that this course may be successful, the ox which I showed in the fourth class, at the last Smithfield show, and which obtained the prize in that class, was by the largest bull I have, from a cow so small, that I culled her after she had bred that one calf. It must be admitted that the theoretical reasoning which Mr. Cline adduces in support of this recommendation appears to be very conclusive; but, even in the restricted sense in which I understand it, there is some doubts whether it is practically correct. The most successful cross between two different breeds of cattle, of which I am aware, was the one between a Durham bull and a Galloway Scotch cow, made by Mr. Charles Colling. The produce from this cross sold for enormous prices at his sale, and at the present day a majority of the best short-horned cattle are descended from it. My opinion, then, the result of my own practical experience, is, that if a man considers the female animals which he possesses to be smaller than he wishes, he may safely put them to a male of large size, provided he is well bred, of good quality, and is well shaped. But I am bound to add, that I know, in giving this opinion, I differ from the most skilful and successful breeders with whom I am acquainted.

It follows from the above observations, if they are correct, that the first and most indispensable object which all breeders must try to obtain, whatever may be the sort of animals they wish to have, whatever may be the shape or size they prefer, is that the male animal which they select shall possess a strong and healthy constitution. This is absolutely essential; but it is also most conducive to their success that they shall, after due consideration, make up their minds as to the qualities which they wish their stock to possess; that, having made this decision, they shall steadily pursue the object they have in view, and endeavor to select such males as shall be likely to get offspring possessing these qualities; that they shall carefully and candidly examine the females from which they intend to breed, observe the faults in shape or quality which prevail among them, and select males who shall possess corresponding perfections. That the safest mode of ascertaining what are likely to be the qualities of the produce from a male in future is, where there is the opportunity, to see what are the qualities of the offspring already produced from them; then, the next to this is, to observe what are the qualities of the family to which he belongs; and that in the case of not having the opportunity of making use of either of these guides, they may assume that it is probable that the qualities of the individual himself, which in all cases ought to be attended to, will, if he is well bred, descend to his offspring.

It has already been said that there are two classes among the farmers who breed cattle and sheep; the one, of those who breed bulls or rams, and the other, of those who breed oxen or wethers for the purpose of grazing only: the above observations are intended to apply to both. But much more attention ought to be paid by the first of these classes to the selection of the animals from which they breed than is absolutely necessary in the other. This is essential to their own interest, because a male animal very often shows faults in his shape which if he had been castrated, would not have appeared. It frequently, therefore, happens that the produce from a bull or ram may prove excellent cattle or sheep for grazing purposes only, but may be totally unfit to be kept as the sires of future stock. Their duty also to those who hire or buy from them imposes upon them the obligation to pay the strictest and most minute attention to the qualities of their male animals; more particularly, they are bound not to offer to their customers any one, of the health of which they have any reason whatever to doubt, whether this doubt arises from any weakness of constitution, which may have appeared in the individual himself, or whether it arises from their knowledge of the family from which he is descended. They are bound also, not to keep as males any animals who are not perfectly well bred. It does not follow from this, that a long pedigree is in all cases necessary, although it is generally desirable; but it sometimes happens that a female, of whose pedigree the owner is ignorant, will have produced offspring which have all possessed extraordinary merit, and which have proved themselves good breeders also; a male descended from such a female may be considered perfectly well bred on her side; and will, very possibly, prove a better sire than many whose pedigree on paper is much longer.

In paying this minute attention to their occupation, the breeders of male animals have some advantages not possessed by others: they have generally the opportunity of knowing accurately what are the characteristics of the families from which they breed, an opportunity not possessed by those who breed only for grazing purposes. In order to make a proper use of this advantage, they ought to keep accurate pedigrees of their cattle and of their sheep, and as far as possible, when they put the males and females together, recollect what have been the respective qualities of the ancestors of each. They have also the opportunity, by using a male cautiously at an early age, of knowing by experiment, whether the stock produced from him is good or bad, before they run the risk of injuring their stock materially by using him largely. This may be ascertained with sufficient accuracy when the produce are very young; for an experienced breeder can judge with tolerable certainty what will be the shape of a calf or a lamb when it grows up, by seeing it soon after it is born, and before it has begun to lay on fat. Nor is it necessary to see many of the produce for the purpose of deciding what its general characteristics will probably be. I admit that in saying this I am speaking more from my experience as a breeder of cattle than a breeder of sheep, but I believe the same observations will apply to both. It is certain, however, that seeing four or five calves from a bull, ought to be a sufficient guide to the breeder as to whether he will be valuable as a sire or not. Unless there is a family likeness which generally pervades through the produce from a bull, although he may be valuable as the sire of oxen, it will not be safe to use him as the sire of bulls. The seeing, therefore, four or five calves will prove to the breeder whether there is such a family likeness among them, and whether it exhibits itself in such qualities as indicate that when they grow up they will be valuable animals.

There is one failing to which all breeders are liable, but to which the breeder of male animals, from the greater interest attached to his occupation, is more peculiarly liable, and against which he ought most carefully to guard himself;

this is, too great a partiality for animals bred by himself. In order to guard against this he ought to occupy himself more in looking for faults than in discovering merits in his stock; he ought to listen to every criticism he hears made upon them, even by those whose judgment he does not hold in high estimation—not, of course, with the view of being satisfied at once that the criticism is correct, but with the view of satisfying himself, by accurate and candid examination, whether it is so or not; and he ought frequently to see the stock belonging to other breeders, and fairly compare its merits with those of his own.

I think it most probable, that in the foregoing observations nothing will be found which will give new and useful information to practical farmers; but I have been induced to submit them to the English Agricultural society, because I conceive that one of the great objects of that society is the diffusion of knowledge connected with every branch of farming. The best way in which it can be enabled to effect this object, is by those of its members who have paid attention to any of the divisions of farming operations, communicating to the society the results of their practice and experience. It will then be for the society to circulate, by any means in their power, such of these communications as it shall appear to them are likely to be useful to those engaged in the cultivation of the land. With this view I place this paper at their disposal.

Law Reforms.

It was, we believe, Sir Matthew Hale, who called law the perfection of reason; and as the means of right, and the prevention of wrong, it is entitled to the respectful consideration of all. There is reason, however, to fear, that law is sometimes perverted from its high purposes and legitimate functions, and made to minister to the ambitious, the selfish, the avaricious, and the baser passions of mankind; that right is forgotten in acquired power, and that wealth, rather than justice, is the lever that actuates too many of its ministers and professors. It cannot be disguised, that practices are covered with the sacred mantle of the law, and performed under its ostensible sanction, that, freed from this protection, would subject the performer to the most serious charges, affecting both honor and honesty. So flagrant have some of these practices become; so utterly subversive of all right and justice; so demoralizing and oppressive in their results; that public opinion had been gradually awakening to these enormities, and was prepared to demand their abatement. It has become apparent, that the system of law practice, or carrying into effect the decisions intended to give justice to all, the humblest as well as the highest, needs a thorough reform, or a state of things will soon, if it has not already in a great degree arrived, in which redress of wrong to the poor will be hopeless, the name of justice a mockery; petty quibbling and a scramble for costs reign triumphant in the temple of the laws; while the great mass of the people will be compelled to assume the power they have delegated but never alienated, the power of doing justice to themselves. These facts, so obvious to all, were regretted by the more honorable and high-minded part of the profession, who felt that the disgraceful practices of some, would be used as a reproach to all, and they were of course willing to adopt a system of reform that should remove the evils so justly obnoxious, and which had enabled the litigious pettifogger, the half learned practitioner in the courts of law, to cheat the public, accumulate costs, and ruin thousands.

The iniquities and extortions under colour of the law, though known to be frightful, had never been fully unveiled to the people; but now, when the public feeling seemed to demand expositions of this nature, the press began to cooperate in showing up the manner in which the framer, the expounder, and the administrator of the laws, in too many instances, acted more with regard to the fees, than the sacred principles of right. The leading paper of the Knickerbocker for January, 1839, evidently by 'authority,' was an admirable, though an alarming exposition of the practices resorted to, to delay justice, procrastinate causes, accumulate costs, and ruin the clients in our courts. The 'Memorial,' a paper conducted with spirit and ability at Seneca-Falls, was set up with the avowed purpose of advocating a reform in our system of jurisprudence, and its successive numbers have demonstrated beyond a peradventure the necessity existing for such a movement. The practices exposed in these papers, as resorted to by some from whom the public had a right to expect better things, are such as would, or should, exclude the perpetrators from the society of honest, honorable men. The quibblings, the repetitions, the endless accumulation of words and folios, resorted to, to increase the costs, and retard, if not utterly subvert all salutary action of the law, revealed in the official records and papers there published, show a system of peculation, not to say swindling, worthy of the best instructed disciples of Daines Barrington.

In compliance with the wishes and the demands of the people, a commencement was last winter made, which, if followed up as it must be, will restore the administration of the laws to its high standing, which in the nature of things it deserves. The great object must be, to simplify and render all the laws as easily understood as possible; to reduce the costs to a liberal, not an exorbitant compensation; to render the means of justice speedy, and open to all; and to punish without mitigation or escape, the man who degrades the name of lawyer by extortion, or legal dishonesty. A good beginning was made in the reduction of costs in some of our higher courts, at the last session; and the schedule of fees must undergo still further examinations and reductions.—None are more interested in these things than the farmer, from whose hard earnings so large a portion of these exorbitant fees are annually wrung. It is he who suffers most from the law's delay, and who pays most dearly for the vexations and wrongs, which the insolence of wealth enables the avaricious or the unprincipled to heap on the poor. On these and kindred subjects the people must and will be heard. In submitting to the government of laws, mankind yield or delegate a part of their native rights, to secure the peaceable use of all; when this concession fails, they are at liberty to resume. Men submit to laws to escape from oppression; when the elements of oppression and wrong become concentrated in the laws themselves, by the weakness or the wickedness of the enactors, then they come in contact with the unalienable rights of man, and will be found but threads of burnt tow on the limbs of a giant.

If the profession of law has become so thronged, that such practices are necessary to give its followers a living, then let them go back to the field or the workshop and obtain an honorable livelihood, where they can eat honest bread. Our country is broad, our lands are fertile, competence and honorable distinction may be found in pursuits where temptations to fraud are not so strong as in the profession alluded to, and in which a man may be useful without the constant danger of becoming infamous. Many of the noblest spirits of our land are lawyers; would that we were not compelled to add, some of the meanest and vilest are also lawyers. The first are as deserving of honor, as the latter are of contempt. Any system of reform that shall have a tendency to do away the evils so justly complained of; give equal and exact justice to all; strike at the root of all extortion and oppression, will be sure to receive the support of the first, and encounter the opposition of the last. By their fruits ye shall know them. We hope this subject will not be permitted to sleep; that the advantage gained will not be lost; but that a reform, equitable, just and thorough, will be carried through our system, retaining all that is valuable, giving ample compensation for services performed, but placing the power of oppression, contumely and wrong, beyond the reach of those who now are the dread and the scourge of the people. In this reform we are sure of the support of the intelligent, the able, and the honorable lawyer; while in the ranks of opposition will be found those who fight for spoils, and whose censure is praise.—*Genesee Farmer.*

Culture of Ruta Baga.

[*From the Farmers' Monthly Visitor.*]

Hon. Isaac Hill—Dear Sir—Believing ruta baga to be of great value to the stock farmers, and as the season for sowing it is at hand, I send you an extract from my farm journal relative to my mode of culture the first year, though, as it was my first experiment, I am far from thinking it to be the best mode. However, as I was pretty accurate in detail, its publication may be of use to my brother farmers, by inducing some one better acquainted with its culture than myself, to point out the errors in my process.

In the fall of 1836, I broke up three acres of green sward; the soil a stiff loam; upon which I carted 150 single loads of coarse manure, and in 1837 planted with potatoes, there being nothing peculiar in the management, or extraordinary in the crop.

In the spring of 1838, I carted on sixty loads of well rotted manure, which I ploughed in, so soon as the ground was sufficiently dry, and on the 27th May I again ploughed, harrowed, and after rolling smooth, marked it into squares of eighteen inches, and planted by dropping two or three seeds in each intersection, which was done by taking the seed from a box, say a common tin dropping box, with a single hole in the top. I sowed from the 1st to the 4th of June; on the 23d began to weed, thinning out where the plants were too crowded, and setting out where deficient, which I continued to do occasionally when other work did not press, till the 28th July. On the 26th October, I began to pull and cut, finishing on the 9th of November; and I found the plants last pulled as uninjured as the first, although they had been exposed to several severe frosts. They were pulled by hand, the workmen striking two plants together to shake off the dirt, and then throwing them down, where they lay spread for three hours to dry the loose dirt that still adhered to them; the tops were then twisted off, and the plants thrown into heaps for carting, so that each root was handled three several times. They might have been got into the cart with less labor, but my object was to get them into the cellar in a tolerably clean state. Having heard much of the difficulty of keeping them in cellars, from their tendency to rot, I stored in one cellar 1,500 bushels without injury to a single root, and I have now, (May 5,) more than 100 bushels as full and as fair as when first placed there. The cellar was thirty feet square, on the bottom of which, eight inch timbers were placed, and covered with plank two inches apart. The whole was divided into two bins, with one foot space between the bins, and one foot between the bins and cellar wall; the sides of the bins being made with narrow boards, with a space of four inches between each board.

I fed out my twelve hundred bushels to my sheep, six hundred to my horned cattle, and the remainder to my horses. They all ate with avidity, preferring them to potatoes. For my horses and cattle they were merely cut with a spade; for the sheep they were passed through a vegetable cutter. They were carted in two carts, each containing thirty baskets holding more than a bushel, and weighing seventy-four pounds. The number of baskets was twenty-one hundred, and the whole weight *seventy-seven tons.* Number of roots, 36,000—as put in the extract from my journal alluded to above. I am, sir, very respectfully, your ob't servant,

LEONARD JARVIS.

Ruta Baga,		*Dr.*
To interest on three acres, at $100 per acre, ...		$18
Twice ploughing three acres,........................		6
Harrowing and rolling, ...		4
Seed, ...		2
To 130 days' work on above, viz: 9 days sowing, 85 weeding, hoeing and setting, and 36 drying and cutting—130 days, or five months, at $13 per month,..		65
To 22 weeks' board, at 9s. per week,................		33
Cr.		$128
By 2,100 bushels, at 10 cents, ...	$210	
Profit, estimating at 10 cents, ...		82
Claremont, May 5, 1839.		$210

Remarks.—Compared with the price of other crops, this ruta baga was richly worth twenty cents the bushel: say it was worth only fifteen cents, the nett profits on these three acres of ground were *one hundred and eighty-seven dollars.*

We are highly pleased to exhibit this evidence from one of the first, and we believe the most extensive practical farmer in the state of New-Hampshire, in favor of the root culture. He shows by this experiment what much manure will do for the ground for a succession of years: it gives double payment in a single year for the labor bestowed; and this double payment will extend itself into a series of from four to ten years, according to the capacity for retention of the soil to which it is applied.—*Ed. Far. Mon. Vis.*

We call particular attention to the following article from the New-England Farmer. It is fraught with truth.

Cause of High Prices.

But one great and prolific source, as we honestly believe, of high prices, deficient labor, the luxury, waste and servility which prevail among us, is in the multiplication of banks beyond the business wants of the community, the extension of paper money, and the abuse of the credit system. Our honest conviction is, that the enormous increase of bank capital beyond all reasonable limits, is destined to prove to the country in its various influences a source of immense evil. The calamities from which we have just escaped, are to be directly traced to this as their great origin; and, as matters are now going on, we have only to look forward to another explosion, as disastrous as that from which we have so recently recovered—for come it must. Its arrival in the natural course of things is as certain as the descent of water upon an inclined plane, or the passing of the sun over the meridian. The creation of immense amounts of purely artificial and fictitious capital, produces a dangerous delusion with individuals and on the public mind. If its effect were merely to increase the facilities and stimulate the powers of production, it would so far be well; but this it does not do excepting in a very partial degree, and in an indirect form. This money is loaned to what are called men of business—a class of men, who as far as they are money brokers, are the mere exchangers of commercial products, without any increase of their value, or speculators in lands, who add little or nothing to the wealth of the community. The increase in the nominal value of real estate is of no advantage to the community, unless it is based upon some positive improvement, or increased productiveness of the soil. If a piece of land is sold to-day at five dollars an acre, and next week it is valued at ten dollars an acre, without any change whatever in its condition, how is the community in any respect benefitted, or its wealth increased? But on the other hand, the obtaining of land for agricultural purposes, for production, and the actual creation of wealth, is by this enhanced price rendered the more difficult to the man whose labor is his only capital—the man of all others in the community the most to be encouraged.

Then, again, the abundance of money itself lessens its value, and operates to raise the scale of prices. The facilities of procuring credit and money induce recklessness—lead to all kinds of speculation—create a distaste for labor—encourage the most luxurious expenditures—relax the bonds of moral principle—and convert the community into a population of gamblers. It is the true secret of the enormous frauds with which our community has been convulsed within the last two years, and of the prevalence of the gross and immoral principle, that a neglect to pay one's debts to a corporation, or a fraud upon a corporation, is a different matter from one committed upon an individual.

In fine, it is the moving cause and prolific source of speculation—speculation, a matter pregnant with evils, and from which no more good has accrued, or can ever accrue, to the community, than from any other form of lottery gambling. These are, to a certain and considerable extent, the causes of the high prices of living; and under this system they must continue until we have another periodical explosion. There is no cure or preventive. There is not moral soundness enough in the community to afford any hope of amendment or of change, until another fit of delirium tremens brings us up, as the sailors say, "all standing;" rubs out old scores, and then leaves us to start again in a new course of unbridled profligacy, vulgarly called prosperity.

Pruning.

A great variety of experiments made in Europe by Knight, Van Mons, and Thaer, and in this country by Buel, Kenrick, and others, have been made on the subject of pruning trees, and though the results did not perfectly agree on all points, yet they seem to fully justify the general conclusion that the best time for pruning trees is that period in midsummer in which there appears a cessation of the sap's ascent, and which lasts some three or four weeks. Those who have paid attention to the growth of trees must have remarked that the period of increase is divided into two seasons, during the first of which, or the one most active, the shoots that form fruit, flower or seed buds are formed; and the other or later summer's growth is confined to the shoots that produce wood buds only.* "After the second growth is completed, the effects of the descending sap in the formation of new bark, is apparent in the healing up of new wounds, in parts of the stem or branches, which now proceeds with more activity than during any other season of the year. Branches pruned off smooth at the stem, though the latter be young, healthy, and containing a perfect pith, before or shortly after the completion of the midsummer's growth, do not produce shoots from the edge of the wounds caused by their removal, which always happens, more or less, when pruning is performed on free growing trees after the fall of the leaf, and before the full development of the spring shoots and leaves. It is to be observed, however, that the reproduction of branches from the edge of a wound is greatly assisted by leaving a portion of the branch or shoot, on the parent branch or stem." [Treatise on Planting.]

The end desired to be attained by the operation of pruning must be kept steadily in view, or injury instead of benefit may be the result. If the tree is intended for timber, the leaves and buds that elaborate the sap, and increase the trunk by the formation of an annual circle of new wood, should be kept as far from the root as possible, as in this way only ean the greatest quantity of timber be produced. In this case, the trunk should be kept free from branches, the leading shoot should carefully be preserved, and the top kept in a crown like form. Nature must be followed in this respect, and the tall beautiful trunks of our native forest trees will be the result. For fruit, a low branching top, spread and exposed to the sun as widely as can be, is to be preferred; and hence, the leading shoot when the tree is at a proper height must be carefully cut out, and the lateral branches cut and pruned with direct reference to this effect. Fruit trees must be pruned frequently, or their tops become woody, close, and the fruit will necessarily prove inferior. —*Genesee Farmer.*

---

* We believe this is an error. Nature provides wood buds first, and fruit buds last. Trees have always leaf buds, though they do not always have blossom buds. Hence, a tree that bears abundantly, and bears its fruit late in autumn, is seldom an annual bearer, because it requires all its sustenance to mature its fruit, and provide wood buds for the coming season. And hence, trees ripening their fruit early, as the cherry, gooseberry, currant, early apple, &c. are often annual bearers, because the season permits them to ripen their fruit, mature their wood buds, and also to produce new fruit buds for the coming season. A ring-barked limb will give fruit buds, because the elaborated sap is all retained in it; while if not ring-barked it might produce only wood buds, because a portion of the elaborated sap passes to the trunk and roots.—*Cultivator.*

Eggs.

Almost every body loves good fresh eggs, and with or without glasses or silver spoons, can contrive to eat them; whether boiled or fried, raw or roasted, made into custard with sugar and spices, or swallowed gently with a bordering of old port, they agree with the palate and the stomach, and neatly laid out with fair slices of bacon, they form a repast within the reach of all, and to be despised by none. But though most farmers keep fowls, and *raise* their own eggs, there are many who have not yet learned the difference there is in the richness and flavor of eggs produced by fat and well fed hens, and those from birds that have been half starved through our winters. There will be some difference in the size, but far more in the quality. The yolk of one will be large, fine coloured, and of good consistence, and the albumen or white, clear and pure; while the contents of the other will be watery and meagre, as though there was not vitality or substance enough in the parent fowl to properly carry out and complete the work that nature had sketched. In order to have good eggs, the hens should be well fed, and also provided during the months they are unable to come at the ground, with a box of earth containing abundance of fine gravel, (if of limestone, so much the better,) that they may be able to grind and prepare for digestion the food they receive. Fowls form no small item in the profits of the small farmer, and few creatures better repay the care and attention they receive. Of eggs, those of the domestic hen are decidedly the best; but those of both ducks and geese may be used for some of the purposes of domestic cookery. Eggs ean be kept any length of time, if the air is perfectly excluded, and the place of deposite kept at a low temperature.*—*Genesee Farmer.*

An account of a comparative trial of stable manure and bone dust for raising turnips on a clay soil.

BY MR. HENRY MAXWELL, OF CALDERWOOD.

The following are the particulars of the turnip crop which was raised by stable manure and bone dust on Sir William Maxwell's property of Calderwood, this season.

The nature of the soil where the turnips grow may be described as a strong loam on a retentive clay bottom. Before draining, the field generally was very wet and sour, but a thorough application of the cross or branch drain system completely divested it of all moisture; and as the ground was ploughed and cleared under favorable auspices, the condition of the land at the time of receiving the seed was very satisfactory. It may be proper to remark, that the field, which was old lea, was drained in the beginning of 1832, a crop of oats taken off it during that season, and prepared for turnips during last spring. In addition to the quantities of manure laid on the land, as will be found in the statement below, seven and a half chaldrons of lime, of excellent quality, were applied to each acre (the Scotch). The seed, which was of the finest quality (procured from Mr. Lawson,) was all deposited at rather an early period. Where stable manure was applied, the braird came away at first more rapidly and vigorously than was the case with the bones; but, ultimately, the bones gained ground, and, if any thing, got rather the start of the stable manure in point of *shaw* or leaves. The whole field brairded beautifully, with scarce an exception, and the crop did not suffer in any degree from the ravages of the fly. In order to ascertain the results of bone and stable manure in regard to the produce of turnip per acre, the most accurate calculations and trials were made; and I have no hesitation in affirming the correctness of the statement in all particulars. In conclusion, I have merely to remark, that the quality of the soil is by no means particularly well adapted for turnip culture, partaking, as it does, rather too much of the clayey character, for which reason also, there is little doubt that the comparatively unfavorably development of the effects of bones as a manure is chiefly to be ascribed. As to the quality of the turnips produced, the specimens which I have sent to Mr. Lawson's very interesting agricultural museum will best testify. They were carefully selected, with a view of furnishing a fair average of each description. This is the statement referred to.

Swedish—30 cart loads stable manure, per Scotch acre, produced	29 tons.
60 bushels crushed bones, per ditto,	24
Dale's Hybrid—30 cart loads stable manure, per ditto	33
60 bushels crushed bones, per ditto	31
45 ditto ditto, per ditto	29
Yellow Bullock—30 cart loads stable manure, per ditto	29
60 bushels crushed bones, per ditto	28
Globe—30 bushels crushed bones, per ditto.	25
25 ditto ditto, per ditto ditto	23 ton 18 cwt.

No stable manure.—*Quarterly Journal of Agriculture.*

---

* As our cotemporary teaches us how to *make* good eggs, we beg to reciprocate the favor, by advising him how to *cook* them. To be nutritious and healthful, and to suit most palates, the yolk of an egg should not be cooked hard, and the white should be merely cooked to a jelly, the consistence of a custard. This is best accomplished, neither by boiling, frying nor roasting—but by caudling, that is, by turning upon it scalding water, either in a caudler or other close dish. In this way eggs may be properly cooked; and by repeating the hot water, or leaving them to lay in it a longer or shorter time, they may be easily graduated to the liking of every one, without trouble or waste.—*Cultivator.*

On the comparative value of the Turnip and Potato Crops.

Swedish turnips should be sown on or before the middle of next month; the different kinds of the Aberdeen and Dale's Hybrid, about the latter end of it, or early in June. The Globe, Norfolk, and Tankard turnips may be sown from the middle of June till the middle of July, but there is better chance of success when they are sown from the middle till the latter end of June.

Some farmers complain of the succeeding crop being less productive after turnips than after potatoes; for our own part, we never saw any just ground of complaint where the culture and management of the turnip crop was judiciously performed; and we consider the potato crop to be comparatively exhausting, and less profitable than turnips. This we shall endeavor to show. The same labor and manure is necessary for potatoes with this exception, that the farmer has the advantage of preparing his ground for turnips at a comparatively slack season, and every opportunity afforded for thoroughly eradicating weeds, which advantage, (and it is by no means a trifling one), is not allowable at the early period when potatoes are put into the ground. The potato crop is chiefly transferred to the market, and consequently returns a very inadequate quantity of manure to the soil; whereas the turnip crop, with rare exceptions, is consumed upon the farm where it is produced, and by the large quantity of valuable manure accumulated by their consumption, turnip is the most enriching crop under cultivation we know of.

TO SEED AN IRISH ACRE WITH TURNIPS.

The produce of an Irish acre of turnips may be reckoned at 40 tons, which will maintain (at least) four horned cattle for five months. Each of these will make 1*l.* per month in value during that time, amounting to		£20 0 0
And the quantity of manure made during that time will be worth		16 0 0
		£36 0 0
Deduct price of seed		4 0
		£35 16 0
On the other hand, an acre of potatoes may be calculated to produce upon a fair average about 400 bushels, which at 1s. per bushel, amounts to	£20 0 0	
Deduct price of seed	1 15 0	
		£18 5 0
Leaving a balance in favor of turnips of		£17 11 0

And the loss of labor, and expense of transferring the potato crop to market, far more than counterbalancing the expense of attendance of cattle, &c.

We are aware that many farmers derive a larger produce of potatoes per acre than we have mentioned, but this is only the exception, not the general or average produce.

No crop, which can be raised at so cheap a rate will maintain such a number of animals per acre the consumption of which will return such a large quantity of valuable manure to the soil, nor enable the farmer to increase the fertility of his farm equal to the turnip; and we are happy to see that their culture is yearly extending, and we hope ere long to see the whole farmers in the kingdom thoroughly alive to its advantages.—C. *in Farmers' Magazine.*

The Productive Powers of Nature.

The powers of nature to create vegetable productions appear never to diminish; the process goes on year after year with increasing energy, and brings forth an increase of vegetable matter to be again decomposed and returned to the soil. This is the natural process by which the decomposing vegetable matter which we find in the soil is formed; and there has been a continual succession of production, decay, and reproduction, of vegetable matter going on ever since nature first sprung into existence, producing vegetables which, when dead, are decomposed into the elements of which they were originally formed.

No loss is sustained by the decomposition of vegetable or animal matter in the soil; all is reduced to the first elements of plants which give fresh energy to vegetation by again entering into vegetable composition.

Thus the process of the growth and decay of vegetable matter goes on in a continual succession, and the decay of one crop becomes the nourishment of the next.

When nature is left to herself, the accumulation of decomposing vegetable matter on the surface becomes great; and if the soil is not possessed of the property of hastening their decay, the vegetable matter is merely increased on the soil, without adding to its productive powers.

On a careful examination, we think, it will be found that the production of vegetables never exhausts any soil; the yearly growth of grass with its decay, adds yearly to its productiveness, and even a plentiful crop of weeds, when allowed to decay on the land which produced them, has the same effect; and thus it is, that land, which has been worn out by close cropping, is by slovenly farmers left for nature to improve.

When the natural pasture is consumed by stock it is converted into animal food for man: and the excrement of the stock being left on the soil forms a rich decomposing animal manure, which gives to the soil increased energy to reproduce an increase of vegetable food for an additional quantity of stock.

Pasture land is full of vegetable fibre, from the surface down as low as the roots of plants descend. Some are the recent roots of grasses, others are those of every stage of decomposition. In arable land scarcely any vegetable fibre is to be found; this circumstance should teach us, that to form a good pasture, we should fill the soil with vegetable fibre as a manure, where we convert arable into pasture land.

The very small proportion of vegetable matter which is contained in the most productive arable soils, would almost seem to indicate that their richness does not depend on the decomposing vegetable matter, but on something else; for if all the straw or refuse of the crops it produced, was returned to it after it had passed through the stomach of some animal, this would scarcely be equal to one-third of what the earth produced.

A judicious succession of crops, and a profitable consumption of the produce by sheep on the ground, return to the soil such a quantity of manure as to give an additional means of increasing its productiveness.

"Water is necessary to the growth of plants. It is essential to the juices or extract of vegetable matter which they contain, and unless the soil, by means of comminution. be fitted to retain the quantity of water requisite to produce those juices, the addition of manure will be useless. Manure is ineffectual towards vegetation, until it becomes soluble in water; and it would even remain useless in a state of solution if it so absorbed the water as entirely to exclude the air: for in that case the fibres or mouths of the plants would be unable to perform their functions, and they would soon drop off by decay." 179, Steward.

It is necessary that the animal and vegetable matter in the soil should have this decomposing disposition, and the soil have it in proportion, to the proper admixture of the materials of which it is composed.

A certain degree of heat, the influence of the atmosphere and water, are necessary to carry on the decomposition of animal and vegetable matter in the soil. The best constituted soil therefore has the power of imbibing, retaining, and giving up to plants a proper degree of heat, air and moisture. When the atmosphere is warm, moist, and sultry, vegetable life is in the greatest vigor, which would indicate these to be necessary to vegetable life if not the very principles on which it depends.

Soil should not only have an affinity for the moisture of the atmosphere, but it should also have the property of readily transmitting it to the vegetables which grow in it.

The soil, therefore, which is best adapted for retaining and transmitting in all circumstances of wet and of dry weather, the necessary quantity of moisture to growing plants, may be reckoned the best and most productive.

If we impart to any soil that which induces vegetation, we improve it and increase its productiveness; but if we in any way withdraw from it that which tends to produce vegetation, we injure it and may make it steril. Barrenness in soil is produced when the component parts of it are so firmly united, that air, water, and the influence of the sun cannot enter into combination with it. When a soil is pure elay, it is sterile and worthless, and so is that which is pure sand. The former resists effectually the enriching influence of the rains and dews, which merely fall on its surface, and either run off or lie there, without penetrating into it. The sun and wind also may beat on it and blow over it, but they can never penetrate its mass to awaken up the dormant energy that lies within; they only have the effect of their repeated attacks to dry and harden the surface, crack it into irregular portions, and more firmly to lock up any languid and dormant principles of vegetable life that may be within the mass. The latter is so porous and loose in its texture that the rain and dews no sooner fall on it, than they pass through it rapidly like water through a sieve; the rays of the sun and the wind evaporate and dry up the last particles that remain, producing only a transitory effect on vegetation, and because they have no regular supply of moisture, the plants soon wither and decay.

The energies of the soil are frequently held in bondage by some pernicious quality inherent in it, or imparted to it, which if neutralized or extracted the soil would become productive.

When light, sandy, and vegetable soils are artificially made lighter, they possess little of the principles of vegetation. The mechanical disposition of a clayey soil is also deranged by improper treatment, such as trampling or ploughing it in wet weather; and although the soil has a full supply of animal and vegetable manure in it, yet the mechanical derangement so totally locks up all its energies, that the fermentation so necessary is altogether stopped, and complete barrenness is the result.

This we have frequently observed to occur from land being trampled by sheep in eating off turnips from strong clay soil during wet weather, in the early part of spring.

They convert the surface into a complete puddle, and when it becomes dry, the parts eomposing the soil are so closely united together, that it is like bricks dried for the kiln, and is entirely unfit for the production of plants. It is evident that the causes of sterility in these soils are opposed to each other; each therefore will require a mode of treatment peculiar to its case. The light, sandy, and vegetable soils, that are too friable, must be artificially rendered more firm; and the too tenacious clay soils must be made artificially friable and kept so, and be pulverized and mechanically altered before we can expect them to become productive. It is evident if these two soils could be mixed together, the mixture, with a proper quantity of vegetable and animal manure, would make a good productive soil.—*Morton on Soils.*

Young Men's Department.

Chemical Catechism—Chapter VIII.

[*From Parkes' Chemical Catechism.*]

OF SALTS.

What is a salt?

When an acid is combined with an alkali, an earth, or a metallic oxide, it forms what is called *a salt.* Such compounds were formerly called *neutral* salts; but that term is now applied only to those salts in which there is no excess either of acid or of base.*

How many salts are there?

As the acids are capable of forming various combinations with the different earthy, alkaline, and metallic bases,† the precise number of the salts is not known.* Probably they amount to nearly two thousand.†

---

* To give the pupil a clear idea of this class of bodies, it may be advisable to set him to form some of the salts from their component parts. He might, for example, be directed to pour a little sulphuric acid into a solution of soda in water, to evaporate the superfluous water, and then to notice the crystallization of the newly-formed salt; for, if the liquor be allowed to stand for a few hours undisturbed in a cool plate, the salt will be seen to shoot into beautiful crystals of sulphate of soda.

† It should be recollected that, besides the various salts which are formed artificially in the laboratory of the chemist. there are many mineral bodies belonging to each of these

What method has been taken to distinguish the different salts?

Modern chemists have adopted a new nomenclature for this purpose, which is as simple and ingenious as it is useful.

How are the salts distinguished by this means?

In this nomenclature every salt has a double name, one part of which indicates its acid, and the other its base; so that, in a collection of many hundred different salts, the composition of each is immediately known by its appellation.

Can you explain the manner in which this is effected?

All substances which are compounds of metallic oxides, earths, or alkalies with the sulphuric acid, are called *sulphates;* with the muriatic acid, *muriates;* with the nitric acid, *nitrates;* with the carbonic acid, *carbonates, &c. &c.*

Do the advantages which we derive from this nomenclature compensate for the inconvenience of changing the names of so many substances?

The new nomenclature, by its scientific classification of bodies, gives such a facility to the acquisition of chemical knowledge, and this alone would have been sufficient to have justified chemists in adopting it; but its contrivance for pointing out the *nature* of the substances bearing the new names, gives it advantages far surpassing every inconvenience attending the alteration.

Describe the nature of some of these advantages.

In conformity with this plan the saline compound, formerly called *Glauber's* salt, is now called sulphate of soda, because it is a combination of sulphuric acid and soda;‡ what was called *gypsum,* or plaster of Paris, a compound of lime and sulphuric acid, is now called sulphate of lime; in like manner, what was called *green copperas* is now sulphate of iron, that substance being a compound, not of copper, as the old name seemed to import, but of *iron* and sulphuric acid.

Have the framers of this nomenclature been equally happy in the choice of names for the salts which are composed with the other acids?

Yes: the principle upon which the nomenclature is formed is such, that the composition of every salt is designated by an appropriate name with the utmost perspicuity.

According to the new nomenclature, what is the common culinary salt called?

Common salt is called *muriate of soda;*§ that is, a composition formed of soda and muriatic acid.

What do you call salt-petre?

Salt-petre is called *nitrate of potash;* it being composed of potash and nitric acid.

What is chalk now called?

Chalk, being a compound of lime and carbonic acid, is called *carbonate of lime.*

You have said that these bodies were formerly called neutral salts,—why is not that term now applied as before?

Because no salt can strictly be called *neutral,* except such in which the acid is completely neutralized by the base, and the base by the acid, so as to be mutually saturated by each other.‖

Is not that the case with all saline compounds?

No: some have an excess of acid, as cream of tartar and most of the metallic salts; others have an excess of base, as common borax.

How are such salts distinguished?

When a salt is found to contain an excess of acid, the preposition SUPER is generally prefixed to its name; but when it does not contain a sufficiency of acid to saturate the base, the preposition SUB is added: thus we say super-tartrate of potash, and sub-borate of soda.

Some salts are formed with acids not fully oxygenized, as the sulphurous and phosphorous acids: how are such salts distinguished?

All salts that are composed with acids ending in *ous,* take an ending in *ite,* instead of *ate;* as *sulphite* of lime, or *phosphite* of potash.¶

* * * *

Having shown the nature of the present chemical nomenclature as far as respects the salts, it will now be necessary to enter on the consideration of each genus separately:—Therefore, What are the generic characters of the SULPHATES?

The sulphates have generally a bitter taste; are always decomposed by the agency of a solution of barytes; and most of them afford sulphurets when heated red hot with charcoal.

Can you enumerate a few of the principal sulphuric salts?

Among the first of them, are sulphate of barytes,* sulphate of strontites, sulphate of potash, sulphate of soda,† sulphate of lime,‡ sulphate of magnesia,§ sulphate of ammonia, and sulphate of alumina and potash, commonly called alum. Besides these, sulphates of the earths, glucina, zirconia, and yttria have been formed, and their properties ascertained, but neither of them has been found useful.

What are the generic characteristics of the SULPHITES?

The sulphites have always a disagreeable sulphurous taste and smell; they are decomposed or changed by the nitric, muriatic, and some other acids which do not affect *sulphates;* if exposed to fire they yield sulphur, and become sulphates: and even by mere exposure to the action of the atmosphere, if moistened with water, they absorb oxygen, and are converted into sulphates. These salts when pure are not decomposable by a solution of barytes, as is the case with the sulphates.

Can you enumerate some of the sulphurous salts?

The principal are the sulphites of barytes, of lime, of potash, of soda, of ammonia, of magnesia, and of alumina.

What are the generic characteristics of the MURIATES?

The muriates, when acted upon by concentrated sulphuric acid, yield muriatic acid in the visible form of vapor. They are among the most volatile, and yet are the least decomposable by fire, of all the salts; not being perceptibly altered by combustibles, even when assisted by an intense heat. They are soluble in water, and are often dissolved in it for the purpose of raising the boiling point of that fluid. They evolve chlorine gas when treated with nitric acid.

Can you enumerate the chief of the muriatic salts?

The principal salts in the muriatic class, are the muriates of barytes, of potash, of soda,‖ of strontites, of lime, of magnesia, of ammonia, and the muriate of alumina.

What are the generic characteristics of the HYPEROXYMURIATES?

The hyperoxymuriates yield very pure oxygen gas by the action of fire, and are thus converted into common muriates; and the stronger acids expel the hyperoxymuriatic acid from these salts, without the assistance of heat. When mixed with combustibles, they detonate with great violence, by mere friction or percussion, and sometimes spontaneously. They are all soluble in water, and some of them dissolve readily in alcohol.

Can you enumerate the hyperoxymuriates?

The chief are the hyperoxymuriates of potash, of soda, of lime, of magnesia, of barytes, and of strontites.

What are the generic characteristics of the NITRATES?

The nitrates yield oxygen gas mingled with nitrogen gas by the action of fire; they give out a white vapor of nitric acid when acted on by concentrated sulphuric acid; and, when mixed with combustible substances, produce, at a red heat, inflammation and detonation. They are soluble in water, and capable of crystallization; and when heated with muriatic acid, chlorine is exhaled from that acid in the form of gas.

Can you enumerate some of the nitric salts?

The more noted are the nitrates of potash,* of barytes, of soda, of strontites, of lime, of magnesia, and of ammonia.

What are the generic characteristics of the CARBONATES?

All the alkaline carbonates are soluble in water, while those of the earths and metals are nearly insoluble, unless the acid be in excess; and they all effervesce, and give out the carbonic acid, when treated with the sulphuric and some other acids.† Some of the earthy carbonates are also decomposed by mere heat without the intervention of any other substance, as is exemplified in burning lime; in which process the carbonic acid is expelled, and the base remains pure.

Endeavor to enumerate the principal carbonates, or bases combined with this acid.

The carbonates of barytes, of strontites, of lime,‡ of magnesia, of potash,§ of soda,‖ and of ammonia,¶ are the principal salts of this class; and that of lime is probably the most abundant in nature.

What are the generic characteristics of the PHOSPHATES?

The phosphates are fusible either into opaque or transparent glass; are phosphorescent at a high temperature; are soluble in nitric acid without effervescence; and are precipitable from their solutions in that acid by lime water. They are partially decomposed by sulphuric acid, but neither the earthy nor alkaline phosphates are decomposable by being heated with combustible matter.

Which are the chief phosphoric salts?

The chief of them are phosphates of lime,** of soda, and of ammonia,†† and the phosphate of soda and ammonia, formerly called microcosmic salt.‡‡

What are the generic characteristics of the PHOSPHITES.

The phosphites yield a phosphorescent flame when heated; and in a strong fire give out a portion of phosphorous, by which they become converted into phosphates. By a very strong heat they are fusible into glass; but if heated with nitre they detonate, and become converted into phosphates. A similar change is also effected in them, if they are treated with chlorine or nitric acid.

Endeavor to enumerate the principal phosphites.

The chief of them are the phosphites of lime, of barytes, of potash, of soda, and of ammonia.

What are the generic characteristics of the FLUATES?

The fluates are decomposed by sulphuric acid, yielding a vapor which corrodes glass, and which, when condensed in water, forms liquid fluoric acid. They are not decomposa-

---

classes which are found native. These will be noticed in their proper places as we proceed.

* Fourcroy reckons that there are 134 *species* of salts; but how many distinct salts there are he has not calculated. Having, says he, 32 acids, and 57 bases, it would appear at first sight that there must be 1824 salts: but there are several of the metallic oxides which cannot combine with many of the acids; which is also the case with silica, one of the earths. However, to compensate for this deficiency, there are several acids capable of combining with two bases at once. These are called *triple salts.* Besides these there are super-salts, and sub-salts.

† Should a young person express his surprise that the number of one class of bodies should be so great, he may be told that nature seems to aim at variety in all her productions. Saint Pierre informs us that there are 6000 species of flies, and 760 different butterflies. Ray computed the number of *species* of insects at ten thousand. There are above 1000 different species of beetles known to exist in Great Britain only, independent of what are found in various other parts of the world.

‡ It is necessary to remark, that when an acid is combined with *two* bases, the names of both are subjoined to that of the acid. Thus we say sulphate of alumina and potash, and tartrate of potash and soda.

§ Formerly the word SALT was confined to muriate of soda. No other substance was then known as a salt.

‖ The propriety of restricting the use of the term *neutral* will appear, if we consider that we have some bases that combine with more than one dose of acid, and thereby form salts which differ in their appearance and properties. Thus we have *sulphate* of potash, and *super*-sulphatet of potash. The one is a neutral salt, the other a salt with excess of acid. These salts are however now called sulphate of potash, and bi-sulphate of potash. These are more appropriate terms, because 100 parts of potash combine with 82 parts of sulphuric acid to form the sulphate; and with twice that quantity or 164 of acid to compose the bi-sulphate. In like manner we now speak of carbonates and bi-carbonates, and of oxalates and bi-oxalates.

¶ When sulphur is fully saturated with oxygen, it forms what is called sulphuric acid, and the salts composed with this acid are called sulphates. But when sulphur is partially oxygenized, an acid is produced called sulphurous acid, and the salts formed with it are called sulphites.

The new nomenclature enables us to distinguish between acids which are partially oxygenized, and those which contain a maximum of oxygen. This is of great importance, because the properties of the salts formed with these acids vary as much as the acids themselves. The salts formed with acids ending in *ic* are generally permanent; whereas salts formed with the same bases combined with acids ending in *ous* are seldom permanent, but by exposure to the air attract oxygen, and are changed into salts of the former kind.

* Sulphate of barytes, or *ponderous spar* as it has been called, is abundant in different parts of the earth. Sulphate of strontites is found near Bristol and elsewhere in abundance. Sulphate of potash, sulphate of soda, and sulphate of ammonia are prepared by chemical manufacturers in many of their processes. Sulphate of lime, sulphate of magnesia, and sulphate of alumina are native productions. Sulphate of ammonia has also been found native in the neighborhood of volcanoes, and sometimes occurs among the lavas of Ætna and Vesuvius. This native production is known to mineralogists by the name of *mascagnine.*

† Crystallized sulphate of soda is composed of about 19¼ per cent of soda, 24¾ sulphuric acid, and 56 water. The fused salt is a compound of 44 soda and 56 sulphuric acid.

‡ In America this substance has been long used as a manure; it is coming into use in this way also in some districts in England. It is plaster of Paris.

§ Sulphate of magnesia is a compound of 33 magnesia and 67 sulphuric acid. It occurs native in the quicksilver mines of Idria, and on the surface of the soil in some districts of Spain. A native combination of sulphate of magnesia and sulphate of soda is found in a crystallized state at Sedlitz.

‖ The most important salt in this class is muriate of soda, which consists of 46.5 of dry muriatic acid and 53.5 of soda. According to the new theory, however, this salt must be considered to be a true muriate of soda only while it remains in an aqueous solution; for when it is reduced to dryness, the muriatic acid and the soda become both decomposed, and the hydrogen of the muriatic acid uniting with the oxygen of the soda, they both pass off in the form of water, while the chlorine of the muriatic acid unites with the metallic base of the soda to form chloride of sodium, which is the true character of our common salt when in a dry state.

Mr. le Goux, in his history of the cocoa-nut-tree, tells us that the inhabitants of those parts of Hindoostan and China which border on the sea-coast sprinkle their rice-fields with sea-water, and use no other manure; and that in the interior of these countries they sprinkle the lands with salt before they are tilled; and that this practice has been followed for ages with the greatest advantage.

In a conversation with the late Mr. Hollinshead, a gentleman who spent many years of a valuable life in making experiments on the employment of salt in agriculture, and in endeavoring to procure an act of parliament to sanction its use, I was informed that from one bushel to six bushel to an acre of pasture land always makes such land more productive; but that a larger quantity would for two or three years afterwards render it actually steril.

* Nitrate of potash (salt-petre) is generated by nature in abundance, particularly in the east: in some districts it appears in an efflorescence on the surface of the soil, from whence, at a certain season of the year, it is regularly swept off two or three times a week, and as repeatedly renewed: it appears that nothing is necessary for its production but the presence of lime, animal and vegetable matters, heat, and dry atmospheric air. The atmosphere furnishes the acid; but how the [illegible] in it, is not known with certainty.

Notwithstanding the prodigious [illegible] of salt-petre collected in the East Indies, it has been calculated that two-thirds of the whole are annually sent into China and other parts of Asia to make artificial fire works. The fire works of the Chinese exceed those of all other nations in variety and beauty.

At Apulia near Naples, there is a natural nitre bed, in which the earth contains 40 per cent of nitre.

In Switzerland, the farmers extract an abundant quantity of very fine salt-petre from the earth under the stalls of the cattle. The urine of quadrupeds contains much potash, and this acquires nitric acid from the atmosphere.

Nitre is used in large quantities in the manufacture of *gunpowder,* every 100 parts of which are usually composed of about 76 parts nitre, 15 charcoal, and nine sulphur.

† There are eleven species of carbonic salts at present known; only four, however, of the native earths are found combined with this acid, viz: lime, barytes, strontites, and magnesia.

‡ Carbonate of lime is not soluble in water, unless the water itself be charged with carbonic acid: it is by this means that nature effects a solution of calcareous masses, to form stalactites, and other beautiful incrustations. Native carbonate of lime is a compound of lime 56, carbonic acid 44.

§ There are two carbonates of potash, the one consisting of 68 potash and 32 carbonic acid, possessing alkaline properties; and the *bi-carbonate,* which is formed with a double portion of carbonic acid, and is incapable of changing the colour of tumeric paper.

‖ Crystallized carbonate of soda consists of soda 21½, carbonic acid 15½, and water 63. The dry carbonate of soda consists of 58½ of soda, and 41½ of carbonic acid. Whereas the bi-carbonate is a compound of 37 per cent of soda, 52¼ of carbonic acid, and 10¾ water.

¶ Carbonate of ammonia, or the common smelling salt, is now much used by the bakers as a substitute for yeast. It consists of one volume of carbonic acid gas and two of ammoniacal gas. The bi-carbonate is composed of one volume of each gas, and consequently is less pungent than the former. The first is composed of 56 parts of carbonic acid and 44 parts of ammonia; the latter of 72 of carbonic acid and 28 of ammonia.

** Phosphate of lime is found in bones, milk, and some other animal matters. It is white, tasteless, and insoluble in water. Entire mountains in Spain are formed of this salt. It is composed according to Dr. Wollaston of 48.5 lime and 51.5 of phosphoric acid.

†† Phosphate of lime exists also in the farina of wheat. La Grange remarks, that a person who eats a pound of farina a day, will swallow 3 pounds 6 ounces 4 drachms and 44 grains of phosphate of lime in a year. It is a curious fact, that the grain of wheat should contain phosphate of lime, while the straw, which was *not* intended for our food, should contain *carbonate* of lime only.

It is remarkable, that though phosphate of lime is always found in the urine of adults, this salt is not evacuated by infants. The rapid formation of the bones, in the first periods of life, requires that there should be no waste of any of the phosphoric salts; and nature, ever provident, has provided accordingly.

‡‡ Phosphate of ammonia is found in urine, and is also prepared by art, to be used as an ingredient in making pastes, to imitate precious stones. It is one of the best fluxes for experiments with the blowpipe.

ble by mere heat, nor altered by combustibles. Some of them are insoluble in water, and others very sparingly soluble in that fluid. Some of them possess phosphorescent properties, and all of them combine with silica when intensely heated in connexion with that earth.

Which are the chief fluoric salts?

Fluate of lime,* fluate of soda, fluate of ammonia, fluate of alumina, and fluate of silica.

What are the generic characteristics of the BORATES?

The borates are all fusible into glass, and with several of the metallic oxides, form glass of different colours. Concentrated solutions of some of the borates, especially that of soda, afford, when decomposed by the stronger acids, scaly crystals of boracic acid. None of the combustible substances have the power of decomposing the boracic salts.

Can you enumerate the boracic salts?

The principal are the borates of lime, of magnesia, and of potash; and the sub-borate of soda, which is known in commerce by the name of borax.

* * * *

What are the generic characteristics of the ACETATES?

The acetates are all very soluble in water; are decomposed by the action of heat, and afford acetic acid when distilled with sulphuric acid. These salts, if exposed to the air when in a state of solution, are soon destroyed, owing to the gradual decomposition which the acid undergoes; an inconvenience which is experienced by the printers of calicoes whenever their red mordant (the acetate of alumina) has been long kept, without being properly preserved from the action of the atmosphere.

Which are the chief acetic salts?

We have the acetates of barytes, of potash, of soda, of lime, of ammonia,† and of magnesia, besides the acetate of alumina of the calico printer, just mentioned.

What are the generic characteristics of the OXALATES?

The oxalates are decomposable by a red heat; and those which are soluble in water are decomposed also by lime or barytes water; and the precipitated oxalate is soluble in an excess of oxalic or of most other acids.

Can you enumerate the principal oxalic salts?

Oxalate of lime, of barytes, of strontites, of alumina, of magnesia, of potash, of soda, and of ammonia.

What are the generic characteristics of the TARTRATES?

When the tartrates are exposed to a red heat, the acid is decomposed, and the base remains. The earthy tartrates are less soluble than the alkaline, but all are capable of combining with another base, and forming triple salts. The tartrates are also capable of combining with an excess of acid, and thus forming what are called super salts, of which common tartar or super-tartrate of potash is a well known instance.

Can you enumerate the principal tartaric salts?

The principal of them are the tartrates of lime, of strontites, and of potash; and the tartrates of potash and ammonia, and of potash and soda, commonly called Rochelle salt.

What are the generic characteristics of the CITRATES?

The citrates are decomposed by the strong mineral acids; they yield [illegible] acid when distilled; and the oxalic and tartaric acids decompose them, producing an insoluble precipitate in their solutions. The aqueous solutions of these salts are not permanent, but are liable to be decomposed by age.

Which are the principal citrates?

The citrates of lime,‡ of barytes, of potash, of soda, and of ammonia.

What are the generic characteristics of the CAMPHORATES?

The camphorates have generally a bitterish taste; they are decomposable by heat, and burn with a blue flame. The camphorate of potash and some other of these salts crystallize very readily.

Which are the principal camphorates?

The camphorates of lime, of potash, of soda, of barytes, of ammonia, of alumina, and of magnesia.

* * *

What are the principle prussiates?

The prussiates, or triple prusiates of potash, soda, lime, or ammonia, with iron: that of potash was formerly called prussian alkali.

---

* Phosphate of soda and ammonia is also found in human urine, from whence it may be procured by evaporation in the state of a triple salt.

According to some modern experiments, it appears that fluoric acid forms a part of the human teeth. It may be conjectured that this was a contrivance of nature, to give more durability to these important organs than they would have had by phosphate of lime only.

† A solution of acetate of ammonia has been used from a very early date in Pharmacy, under the name of *Mindererus's spirit*. It is not crystallizable; for, if evaporated with that intention, it volatilizes entirely.

‡ Citrate of lime is now formed in this country in large quantities, as a preliminary process in preparing the citric acid in a crystallized state. According to Vauquelin, it is composed of 63 acid and 37 lime. From actual experiment I have found that 100 gallons of good lemon juice will generally produce 90 pounds of dry citrate of lime well saturated.

ROHAN POTATOES—The high price of the Rohan Potato last spring, (from $10 to $20 per bushel,) the great demand for them, and their intrinsic value as a farm crop, induces us to give this early notice to the farmers who may wish to cultivate them, that on the receipt of five dollars, if before the 1st of Nov. we will forward to the address of the person sending it, in the manner he shall direct, and at his charge, one barrel of the Rohans, which will probably suffice to plant an acre of ground.

J. BUEL.

Seeds of Evergreens.

☞ WE want to purchase for our friends in the west, a quantity of seeds of the Balsam Fir, Spruce, Hemlock, White Cedar, or Arbor Vitæ, and of the White Pine, and will pay for them a liberal price. In the next Cultivator we will endeavor to suggest the time, and the manner at and in which these seeds should be collected and preserved.

FOR SALE—TWO SOUTH-DOWN BUCK LAMBS.—The subscriber imported, in the fall of 1837, two ewes and a buck, selected from the Earl of Leicesters flock, (Holkham,) of which the above is the progeny. Near Dobb's Ferry, Pa. July 28, 1839.

Sept–tf JAMES A. HAMILTON.

ALBANY SEED STORE, GARDEN and AGRICULTURAL SEEDS, IMPLEMENTS, TOOLS, &c. kept constantly for sale at his Seed Store, 317 North Market-street, wholesale and retail, consisting of a large assortment. It is the intention of the proprietor to test all seeds of which there is any doubt respecting their vitality, by sowing a few seeds in a small pot, before offering them for sale. And purchasers can test for themselves, any seeds of which they are distrustful, by sowing a few in a box of fine earth, and placing it in a warm room, exposed to the sun, where, if kept moist, the seed, if good, will vegetate in a reasonable time. In all cases where seeds prove to be bad, they will be replaced by others, or any reasonable satisfaction made. The proprietor has enlarged his establishment and increased his supplies, and with his experience in the business, together with his facilities for obtaining supplies, through Mr. GEORGE C. THORBURN, and his extensive correspondence and facilities for obtaining seeds, he flatters himself he will be able fully to meet the wishes and expectations of the public, and make the *ALBANY SEED STORE and AGRICULTURAL REPOSITORY* worthy of the high character it has already attained.

Persons ordering Seeds and Implements from a distance, with whom I am unacquainted, without remitting payment, are expected to give references in this city or New-York.

Sept–tf WILLIAM THORBURN.

GREAT SALE of IMPROVED SHORT-HORN CATTLE AND BLOOD HORSES.—The subscribers will sell at auction, on *Tuesday the 10th day of September next*, at the farm of Samuel Allen, on the Niagara river, two miles below Black-Rock, the entire stock of Imported Short-Horn Cattle, for several years past bred on the farm of L. F. Allen, on Grand-Island.

The herd consists of about thirty, including Cows, Bulls, Heifers and Calves. Several of them have been imported by one of the subscribers, direct from England, and with their produce, are surpassed by few animals in the country. In addition to these, every animal offered is the direct descendant of thorough bred imported stock, and of unquestionable purity of blood.

With the above will be sold twenty select and beautiful animals, consisting of pure Devon; crosses of different degrees between the Devon and Improved Short-Horns; crosses of the Alderney and Ayreshire with the Short-Horns. These are Cows, Heifers and Calves, all superior animals.

ALSO—The superb horse "BELLFOUNDER," got by imported Bellfounder, the best thorough-bred trotting horse ever in America, and out of the imported mare Lady Allport, bred by T. T. Kissam, Esq. of Long-Island. The stock of this horse is unsurpassed in the country for size, speed and action—together with several elegant, thorough-bred breeding mares and fillies, and two or three young horse colts, the produce of the above. These animals are of the highest character as roadsters, and as trotters, no blood in the country has excelled them. They are all from the best stables of Long-Island. Also, a beautiful pair of full-bred matched fillies, five years old. All these horses are blood bay.

This entire stock will be sold without reserve, to the highest bidder, commencing at 10 o'clock A. M. They can be shipped within an hour from the farm, on board the steamboats to go up the Lakes, or on board canal boats at the farm.

Catalogues of the animals, with descriptions and pedigrees, will be prepared, and the stock may be viewed at the farm previous to the sale. A credit of sixty days will be given on approved notes or acceptances, payable at a bank either in Buffalo, Albany, or New-York, for all sums over $300.

SAMUEL ALLEN. LEWIS F. ALLEN.

Black-Rock, N. Y. June 25, 1839.

IMPROVED DURHAM SHORT-HORNS.—Mr. WHITAKER'S third sale of high bred improved Short-Horns, by the ship Napier, will be held at Powelton, near Philadelphia, on Friday Sept. 20, 1839, at 10 o'clock A. M.

The subscriber is authorised by Col. Powell to say, that all the best cattle which he has at any time imported, and the improved short-horns which he considered the best in England, were either in Mr. Whitaker's possession, or were derived from his fold. Col. Powell has not the slightest interest in Mr. Whitaker's sales. Philadelphia, July 15, 1839.

ts C. J. WOOLBERT, *Auctioneer.*

NEW-YORK URATE AND POUDRETTE COMPANY, not incorporated, but carried on by individual enterprise. The manures are not divided among the stockholders, as are those belonging to another establishment, but sold to applicants for cash on delivery. Orders are supplied in the order of time in which they are received. Urate 50 cents and Poudrette 40 cents per bushel, with contingent charges for bags or barrels, &c.

The company are daily preparing for use, during the warm dry weather, the materials collected during the past winter, and will have several thousand bushels ready before the first of October next. The material is disinfected and rendered free from offensive smell by a compound, every part of which is in itself a good manure. The experience of the past and present year, 1838 and 1839, on Long Island, has satisfied many of the farmers that these manures have the quickest operation upon vegetable matter, producing greater abundance, and the cheapest of any manure they have ever tried.

Amended instructions for their use, the result of practical experience, will be furnished on application. The effect of Poudrette upon grape vines and morus multicaulis is beyond all comparison. This company are erecting large and extensive works in the vicinity of the city of New-York to prepare the manures; and farmers and gardeners may confidently rely on a supply. Orders, post paid, directed to "The New-York Urate and Poudrette Company," box number 1,211, post-office, New-York; or sent to the store of STILLWELL & DEY, number 365, Fulton-street, Brooklyn, will be attended to. *New-York, July* 17, 1839.

The company will be very much obliged to gentlemen who have used the manures, to give them a statement in writing what has been the result of their use and experiments in relation to them.

aug–4t.

AGRICULTURAL WAREHOUSE and SEED STORE, 79 Barclay-street, New-York. At this old established stand, the subscribers take pleasure in announcing to the public, that they have made extensive arrangements to accommodate farmers in all articles connected with husbandry, viz:—Agricultural implements, a full and fresh supply of Field and Garden Seeds, Fruit Trees, Durham Cattle, Chinese and Berkshire pigs, 10,000 morus multicaulis mulberry trees, publications on rural subjects, &c.

July–3t J. W. WEAVER & Co. 79 Barclay-st. N.Y.

FOR SALE—A Splendid Country Seat in the Highlands, on the Hudson River. That beautiful country residence, known by the name of the BEVERLY ESTATE, containing four hundred acres of land, about two hundred of which are fine level arable soil, of an excellent quality, in a good state of cultivation, and not surpassed by any on the river for fertility; the remainder is fine and thrifty timber land. The situation is the most eligible on the Hudson, extending one mile and a half on the river, with a bold shore and convenient dock, nearly opposite West-Point, and within fifty miles of New-York. The prospect is extensive and diversified, reaching from St. Anthony's Peak on the south, to the bay and city of Newburgh on the north. This estate can conveniently be divided into three farms, giving an equal proportion of front on the river, and of arable and timber land to each. Almost every enclosure is supplied with living springs of the purest water. There is on said estate a plain house, (formerly the head-quarters of Gen. Arnold;) also out-houses necessary to carry on the business of the farm. The single fact that during the whole time the cholera raged throughout the state, not one case occurred within ten miles of this place, is sufficient to prove the unrivalled salubrity of the situation. The facilities of intercourse with the city, that can be reached in four hours, by means of numerous steam-boats, are great, and daily increasing, both as regards pleasure, and the convenience of a near market for produce of every description.

For conditions of sale, apply to STEPHEN A. HALSEY, 189 Water-street, New-York, or RICHARD D. ARDEN, on the adjoining farm. Ardenia, 23d April, 1839. j6t

*Moneys received between the 24th June and 1st of August, in sums of $5 and over. The total receipts are included from post-offices marked with an asterisk.**

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. SEPTEMBER 1839. No. 8.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—Lewis Hill & Co. Richmond, Va.; Bell & Entwistle, Alexandria, D. C.; Gideon B. Smith, Baltimore, Md.; Judah Dobson, bookseller, D. Landreith, and M. S. Powell, seedsmen, Philadelphia; Israel Post, bookseller, 88 Bowery, Alex. Smith, seedsman, P. Wakeman, office of the American Institute, Broadway, New-York; Hovey & Co. Merchants' Row, Boston; Alex. Walsh, Lansingburgh, and Wm. Thorburn, Albany, gratuitous agents; John Thorburn, seedsman and general agent, St. Louis, Mo. E. Valentine, Johnson's Springs, Va. See No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

Our Sheet and its Price.

The first volume of the Cultivator was published at twenty-five cents a year; the subsequent three volumes at fifty cents; and for the fifth and sixth, we have charged one dollar a volume. Many of our original subscribers have probably thought, that we have been extortionate in advancing our price, and that our profits are *now* unreasonable. A plain statement of facts is due alike to them and ourself.

The first volume contained no cuts. The cuts of our present volume will cost us, probably, $300; and the first volume run us in debt nearly $600. But the exhibit of the quantity of matter, and the price of paper—the type setting and paper being the prominent items of expense—will show something of the relative profits, under the different prices which we have charged for the Cultivator. Taking printer's computation, and disregarding fractions,

A No. of our 1st volume, at 25c. contained 50,000 ems.
" 2d volume, at 50c......... 76,000 ems.
" 6th volume, at $1,........ 156,000 ems.

while the price of the paper has correspondingly advanced, until it is now $8.50 the ream; the larger page, and the smaller type requiring stouter and finer paper.

It will thus be seen, that our expense for type-setting, paper and cuts, for our sixth volume is more than quadruple what it was for our first volume, and more than double what it was for the second volume. We gain something in the press-work and mailing, and our subscribers gain in postage—paying no more now than they formerly did for a quarter, or a half, of what they now receive.

Comparatively speaking, the agricultural journals of our country are the cheapest periodicals that are published any where; and as to their superior utility, in promoting the substantial interests of our country, we entertain not a doubt. Take, for comparison of contents, one of the literary quarterly journals, say the North American. This contains, in a number, 248 pages, or 1,000 in a year, and about 1,000 ems in a page—giving an aggregate of 1,000,000 of ems. The Cultivator gives in a year 1,881,000 ems, or nearly double. The North American is five dollars a year—the Cultivator one dollar a year. To correspond with the price of the North American Review, according to the quantity of matter it contains, the price of the Cultivator should be nine dollars a year. Surely no one can hereafter complain of price, however light they may value the matter. And we beg our readers to notice, that the Cultivator is now printed upon a beautiful new type.

The Agricultural State of Scotland.

And what has that to do with American husbandry? it may be asked. Much, we reply. We may learn, from what Scotland *was*, and what she *is*, in agriculture, many useful lessons in farming. We may learn our own errors in practice; and, if we are not too proud, or too conceited, we may learn, from Scotch lessons in farming how to correct them—we may learn from them how to double, at least, the products of our agricultural labor. The history of Scotch agriculture, for the last fifty years, is invaluable to every farmer who would improve his practice. History is wisdom, teaching by example.

We find a valuable essay in the Edinburgh Quarterly Journal of Agriculture, showing what Scotland *was*, and what she *is*, in regard to her agriculture. She was, in 1784, two years after the close of our revolution, as poor as a *church mouse.* She *is now*, perhaps, the richest, in agricultural products, of any portion of Great-Britain, at least so far as regards her arable lands.—The writer describes the face of the country, at the middle of the last century, "no better than that of a bleak howling wilderness," and well, he adds, might the poet at the inn window indite—

"Bleak are thy hills of north,
Not fertile are thy plains,
Bare-legged are thy nymphs,
And bare —— are thy swains."

"In 1784, a few gentlemen, full of zeal for their country, and it may be a little love of society, formed themselves into a sort of hole and corner club, in a coffee-house called the Exchange, situated in the court of that name, near 'the market cross of Edinburgh.' Here, in the enjoyment of agreeable conversation and a good supper, did those worthies talk over plans for the amelioration of the Highlands, and from this nucleus arose the now widely extended and powerful Highland Society." * * * "To say what was the state of agriculture in Scotland, at the date of the formation of the Highland Society, would, to treat of it minutely, require greater scope than the limits of a periodical admit."

* * * *

"But, to take one sweep over hill and dale, corn-field and meadow, we may at once pronounce the agriculture of Scotland, at that period, to have been wretched—execrably bad in all its localities! Hardly any wheat was attempted to be grown; oats full of thistles was the standard crop, and this was repeated on the greater part of the arable land, while it would produce twice the seed thrown into it;—turnips, as part of the rotation of crops, were unknown; few potatoes were raised, and no grass seeds or clover were sown. The whole manure of the farm being put on a little bit of ground near the farmstead, and there they grew some barley of the coarse sort, termed 'bere,' wherewith to make bannocks, broth and small beer, or peradventure, if the farm lay at the foot of the Grampians, to brew a portion of 'mountain dew!' Since the writer can recollect, a great part of the summer was employed in the now fertile shire of Fife, in pulling thistles out of the oats, and bringing them home for the horses, or mowing the rushes and other aquatic plants that grew on the bogs around the homestead. Such was the state of Scotland, with but little appearance of amendment, up to 1792."

The general outline of this picture of wretched husbandry is suited to the present condition of many districts on the eastern borders of our country, though the filling up of the picture would require to be somewhat different.

"Time, with her 'ceaseless wing,' had now brought in another century, and on the arrival of the nineteenth, the richer part of the low country had put on another aspect.—Beautiful fields of wheat were to be seen—drilled green crops and clean fallows every where abounded—the bogs had disappeared—the thistles no longer existed. In the Lothians, all this was carried on to a great extent. The farmers forgot themselves—they were coining money, and 'light come, light go,' was their motto. They went on in the most reckless manner—they began to keep greyhounds, to be members of coursing clubs, subscribed to the 'silver cup,' or 'puppy stakes,' and yelped the same note of folly as their betters in birth, their equals in extravagance and vice. Then followed yeomanry races—the good sturdy nag that would be of use *at a time* in the operations of the farm, was exchanged for a blood weed, and on market-day, instead of rational conversation about matters connected with their own calling, they began to talk '*knowingly*' about the turf. At this time, that is, from 1810 to 1814, the agricultural horizon was the brightest; the gas was fully up, the nation was alive, all was activity and business." * * *

But at this time the battle of Waterloo came, and with it peace and low prices. Farmers could not sustain their extravagance—they had been unable to bear prosperity—and their farms fell into the hands of more prudent managers. We have seen much of the same routine of industry, extravagance and poverty, among the farmers of our own country. Not willing to "*let well enough alone*," they have embarked in speculation, or in pursuits to which they were strangers, and have gone into extravagances and follies, to ape the great, which their means did not warrant, and which neither their comfort nor the welfare of their children required. The consequence often has been, that, like the indiscreet Scotch farmer, their lands have come into the possession of more prudent managers.

But though Scotch farmers failed, from not knowing how to bear prosperity, Scotch husbandry did not retrograde.

"In 1815, the turnip husbandry had got a firm hold in the country—the benefit accruing from it was so apparent, that no convulsion in the market prices could make the farmers forsake it."

Yet the culture was limited, owing first to the want of manure to feed the turnip crop, destined to fatten the farm stock; and 2dly, to the expense of driving their cattle to a distant market. Two discoveries removed these impediments. The first, "the most important," says our author, "that ever occurred in the annals of agriculture, viz. that of *bone-dust*," and the second, the *application of steam*, by our countryman, Fulton, to the propelling of vessels, which enabled the Scotch farmer to transport his fat animals to Smithfield market, at a moderate expense. "So palpable was the benefit to be derived from the use of bone manure, that in a few years there was not a farmer who did not avail himself of it. The farmers could now grow turnips to any extent, and the bare fallow was exploded." We have bone-dust, and poudrette, and other newly discovered means of fertility, which the farmer is shy of buying and using. We have tried them all, and are satisfied both of their utility, and the economy of their application, especially upon naturally dry or well drained soils. They add much to the products of agricultural labor, without any thing like a corresponding outlay. The Scotch farmer could now grow turnips to any extent. He could fatten upon these his stock: and he could send this stock to market at a trivial expense, for the "steam engine had become his drover."

But another—a third improvement followed, which we have yet to learn the value of—we mean *furrow draining*, on flat and tenacious soils. Hear what our author says upon this subject:—

"No man holding land ought to be ignorant of the thorough or Deanston drain. Mr. Smith, deeply engaged in the cotton spinning trade, could not procure a fall of water on the river Teith, ten miles west of the castle of Sterling, without renting along with it a considerable portion of very bad and wet land. Not liking to have a heavy rent to pay for such trash, Mr. Smith turned his powerful mind to the subject, and perceiving the folly of throwing away large sums of money on deep and useless drains, with all the stuff of tapping and boring, to *catch* the water as it were a wild beast for which gins and traps must be laid, hit on the idea of making drains in parallel lines in the hollow of every ridge, cutting them to the depth of thirty inches, filling them with small stones half-way to the surface, above this putting a green turf reversed, and replacing the mould. Following up his first discovery by ploughing deep, he has now a farm of the finest land ever seen; and so convinced is the writer of the utility of this mode of draining, that each year he has been increasing the quantity he has made, and during the last twelve months has put in above fifteen miles. Nor is the Deanston drain confined to those parts of the country where stone or gravel can be procured; the same system can be and is followed with the same effect, by using the Marquis of Tweeddale's tile; or even the poorest farmer, who has not capital to undertake costly improvements, can fertilize his farm by making the thirty inch drains and filling them with brushwood. It is perfectly wonderful to behold the mighty change this thorough-drain system is making in the different parts of the country where it is in operation: wet land is made dry, poor weeping clays are converted into turnip-soil, and even what would formerly have been accounted dry is advanced in quality. Whole parishes in the vicinity of Stirling are completely transformed from unsightly marshes into beautiful and rich wheat-fields, and where the plough could scarcely be driven for slush and water, we see heavy crops per acre and heavy weight per bushel, the quantity and the quality alike improved." * * *

"It is the greatest quantity produced at the cheapest rate that will ever make a prosperous trade. If wheat is low in price, the farmer must bestir himself." * * * "Let him remember that if he can but grow one or two quarters more per acre, he will be in a better position, even with the low price, than he was before." * * *

In speaking of the Highland Society, the writer enumerates the following means which that society adopted as contributing largely to the mighty advance of the agriculture of Scotland:—

"In the days of its youth and feebleness, the Highland Society sent the leaven of the turnip husbandry into all the glens and straths of the north, by offers of small prizes to certain Highland parishes; and the same may be said as to the growth of clover and the finer grasses. As it advanced in strength, (as to numbers and as to cash,) attention was turned to premiums for stock; then came offers of reward to men of science to discover better implements and machines, to diminish friction and consequently draught, such as in the thrashing mill and other parts of agricultural machinery. Still advancing in the scale of intellect and of science, premiums were offered for essays to bring to light the facts connected with chemistry and natural philosophy; and, under the auspices of the society, was set up the Quarterly Journal of Agriculture, a work which has been the vehicle of conveying so much useful information to the agriculturist, that, we humbly venture to say, it ought to appear on the table and book-shelf of every farmer's parlor. After this, the great stock-shows were resolved upon, as another link of union between the society and the practical farmer, at the same time throwing aside all paltry feeling, and making them open to stock from both sides of the Tweed, [*i. e.* from England as well as Scotland.] How well they have succeeded, let the last one at Glasgow bear witness. [This was the most splendid show of fine cattle ever exhibited.] Nor has the society forgotten the beauty of the country, as the premiums offered in regard to planting trees and such-like subjects fully testify; and to sum up all, it may be said, the Highland Society has been a '*point d'appui*,' a rallying point, to which the agriculturists of Scotland might look, and a fostering mother to all who, although strong in talent, were weak in interest to make it public. An ardent lover of the plough and all that can speed it, the writer of this article would advise the society of England [and all other agricultural societies who would be useful to their country,] to look into the annals of the Highland Society, and from them to cull whatever may be of use in the advancement of the delightful science, the culture of the fields.

————————"'the men
Whom nature's works can charm, with God himself
Hold converse; grow familiar day by day
With his conceptions; act upon his plans,
And form to his the relish of their souls.'"

The Highland Society have this year offered prizes to the amount of $17,000, under the following classification:—

Class I.—Agricultural machinery, 500 sovereigns and a gold and silver medal.

Class II.—Essays and reports on various subjects, embracing thirty-one subjects of high interest to the farmer, viz:

1. Geological surveys.
2. Reports on coal districts.
3. Mines and minerals.
4. Products of peat moss, &c.
5. Comparison between different kinds of manure in raising potatoes.
6. Extended application of water and other power to farm purposes.
7. Comparative efficacy of the two modes of thorough-draining.
8. Reports on irrigation.
9. Forest planting.
10. Sheep pastures at high elevations.
11. Improved sheep salve.
12. On crossing the Cheviot with the New Leicester Ram.
13. Cultivation of the recently introduced cereal and other grains.
14. Feeding farm horses on raw and prepared food.
15. Early rearing and fattening of lambs.
16. Insects injurious to agricultural plants.
17. Insects injurious to forest trees.
18. Comparative nutritive properties of grasses.
19. Extirpating ferns from pastures.
20. Thorough-draining.
21. Subsoil ploughing of thorough-drained land.
22. Mole plough.
23. Experiments with manures.
24. Analysis of bone or rape dust.
25. On the effects of altitude on vegetation.
26. Feeding of cattle.
27. Forests of larch.
28. On raising improved varieties of grains.
29. Reports on improved rural economy abroad.
30. Honorary premium for reports on certain districts in Scotland.
31. Investigation of certain points connected with the science of agriculture, viz:

    An essay or memoir explaining, on scientific principles, the mode in which soil operates in producing or facilitating the germination and growth of vegetables.

    An essay or memoir describing and proving, on scientific principles, what is the best admixture of the ordinary elements of soil, for promoting the germination and growth of particular vegetables.

    An essay or memoir describing, on scientific principles, the mode in which lime operates in rendering the soil better adapted for the germination and growth of particular vegetables.

    An essay or memoir explaining, on scientific principles, the effect of drainage, in altering the constitution or qualities of the soil, and increasing its fertility.

    An essay or memoir, showing the nature of the atmospheric influences on soil, in promoting its fertility, including the modification of these influences arising from heat and cold, dryness and moisture.

Class III.—Waste lands—their improvement by tillage.

Class IV.—Crops and culture.

Class V.—Pastures—their management.

Class VI.—Live stock—district competitors.

Class VII.—Products of live stock—butter and cheese.

Class VIII.—The best kept cottages and cottage gardens.

Class IX.—Woods and plantations.

Class X.—General show of live stock and agricultural meeting at Inverness.

Having shown, by our quotations, something of the vast extent of the recent improvements in the agriculture of Scotland, and the influence which its agricultural society has had in promoting these improvements, we have given the above sketch of their premiums, as indicating the means they have adopted, and are adopting, to bring about this great and salutary change—to show how vast a field they occupy—and the great bearing which science is made to have in the improvement of the soil, and in the operations of the farm.

Transactions of the Essex Agricultural Society.

Although we consider our practice in reclaiming wet grounds, as very defective, and not managed upon scientific principles—neither so economical as to ultimate profits, or permanent in improvement as it might be—yet the advantages are so palpable, even under our defective mode of management, as to make it the interest of every farmer, who possesses grounds of this description, immediately to commence this branch of improvement.

The Essex County Agricultural Society have wisely turned their attention to this matter, and made it the subject of premiums. In the pamphlet under consideration, we find five claimants for the prize; and we propose to give an abstract of two of these communications, by way of inducing others to commence the like improvements, as matter of profit, as well as promotive of health, and of the beauty of rural scenery. For there are few things more obnoxious to health than stagnant waters, and there is nothing more disgusting to the eye, in an old settled district, than noisome swamps and marshes.

Timothy H. Brown, attacked a swamp of between five or six acres, in Saugus, the mud in which was from two to twelve feet deep, and which was so thickly covered with briers and bushes, that a dog would have found difficulty in passing through it—and so many stumps and logs that the plough could not enter the soil, though it had been dry. It was of course worth nothing in its then condition. He cut and burnt the brush, dug out the stumps and roots, and reversed the turf, by hand labor, and dug a drain. In the winter following, he drew off the logs and stumps, harrowed the ground thoroughly, in the spring, when but a few inches of the surface was thawed, and about the first of May, planted potatoes. His crop was 927 bushels. His logs and stumps were converted into charcoal.—The land is now, says Mr. Brown, in a state that I can plough it at pleasure. Mr. Brown states the debtor and credit account of the improvement as below.

VALUE OF PRODUCTS.

Proceeds of coal in 1837,	$166 40
do do 1838,	333 33
Value of crop of potatoes, at 50c.	463 50
Value of ashes for manure,	75 00
Value of wood sold,	50 00
Value of wood used,	50 00
Increased value of the land, it being now worth $125 an acre, and originally worth only $12 an acre,	565 00
	$1,703 23

EXPENSE OF IMPROVEMENT.

Levelling and clearing the land,...	$504 00	
Carting the wood and roots,	35 00	
Harrowing, &c.	12 00	
Planting, hoeing, harvesting, &c...	117 00	
Coaling in 1837,	40 00	
Coaling in 1838,	100 00	
		808 00
Profit by the improvement,		$895 23

William Osborn, Jr. made an experiment upon four acres of like conditioned swamp, in the same town, commencing in the autumn of 1837. He adopted much the same course as Mr. Brown in clearing the land, and run a ditch around the piece, and four ditches across it, three feet deep and four feet wide. He put on different crops, as indicated in the following statement of his expenses and value of his crops.

CROPS.

320 bushels potatoes, at 60c.	$196 20
5½ do rye, at $1.25,	6 87
8½ do corn, at $1,	8 50
100 do ruta baga, at 30c.	30 00
20 cwt. hay,	12 00
50 dozen cabbages, at 50c.	25 00
2,000 lbs. squashes,	20 00
Value of fuel,	25 00
	$323 57

EXPENSE.

Cost of land,	$25 00	
Labor, per contract,	86 50	
94 days by help on farm,	70 50	
Seed potatoes,	15 00	
Rye and grass seed,	1 17	
Six cords manure, at $5,	30 00	
Two casks lime,	2 00	
22 days' labor, gathering crops,	16 50	
		246 67
Nett profit,		$77 90

And the land in the bargain, probably worth $400 more.

Experiments with manures.—We subjoin the report of the committee upon this branch of farm economy. It contains suggestions which are of great value; and where manure sells for $5 a cord, as it does in Essex, no branch of farm economy is entitled to higher consideration.

"The Committee report:—That they consider the subject of the making and application of manures, one of the greatest importance to the agricultural interest. Manure and labor are to the farmer, what capital and credit are to the merchant. With them, well applied, the one will add barn to barn, the other store house to store house, till there shall be no room to contain their several wealth; without them they must soon suspend operations, and their farms and their ships pass into the hands of more skilful and industrious owners.

"Many farmers think they cannot afford to purchase manure, and the price *does* seem disproportioned to the immediate profits; but no farmer will say that he cannot afford to make the most of what he has, and to apply it to the best advantage. Many take an honest pride in being able to say, I have raised so many hundred bushels of corn, or so many tons of hay; now to be able to say I have made five hundred loads of manure, is just as much a matter of boasting, for manure will make corn, and hay, and other valuable products, if it be only judiciously applied. Put in the seed and the manure, and the grateful soil will make you a liberal return. It is held to be true by experienced farmers, that he who doubles the expense of labor and manure, will increase his profits and products in nearly a four-fold proportion. In other words, the man who spends half his time upon his farm, and skims over one hundred acres of land and gleans from it fifty bushels of corn and twenty tons of hay, if he should devote his whole energies to his farm and improve his means of making manure, might raise nearly two hundred bushels of corn and eighty tons of hay.

"Some have, in their natural situation and proximity to the sea-board, greater facilities for making and obtaining manure, but every substance of animal and vegetable matter can be mixed with the soil in such a manner as to increase the fertility of the earth; and even the different soils may be mingled so as to produce the same effect.

"The quantity of manure a farmer uses, is a pretty fair criterion by which to judge his character. In Plymouth co. where a premium is awarded to the man who makes the greatest number of loads, a most worthy and truly respectable farmer, the last year, reached the very enviable eminence of 798 loads; the lowest competitor claimed for 350 loads, and bis must be allowed to be an *improving* character. William Clark, Jr. of Northampton, in his statement to the Hampshire, Franklin and Hampden Agricultural Society, represents that he keeps an average stock of eight swine, three horses, and eight oxen and cows; from this stock, with the skilful use of all his advantages, which are not superior to those of many of our farmers, he made from June, 1837, to June, 1838, 920 loads, an honorable monument to his intelligence and industry, which compensates in utility and solid value for what it may want in taste and splendor. Mr. Clark used for compost, 300 loads of sods and soil and 247 loads of swamp muck. His yards were supplied with corn stalks and refuse hay during the winter, and brakes and weeds in the summer, and cleared out twice during the year. It might be supposed that manure so made could possess but little of the quickening and strengthening principles, but those who have visited his farm and seen his fields burdened with their heavy crops, are satisfied that Mr. Clark knows how to make manure and to apply it, and that his fields acknowledge their obligation and pay their due return. Mr. Clark, from such manure, has raised more than one thousand bushels of corn in a year.

"The committee award to Daniel Putnam, of Danvers, for the satisfactory experiment and the full and explicit statement made by him, a premium of twenty dollars.

"They recommend that Mr. Putnam's statement and the letter addressed by Joseph How, Esq. of Methuen, to the committee, be published. For the committee,

"DANIEL P. KING.

"*Topsfield, December* 25, 1838."

[The letters of Messrs. Putnam & How in our next.]

Notes on New-Jersey Farming.

A recent visit to New-Jersey, has enabled us to see more of its husbandry than we have before witnessed in passing across the state by the ordinary routes of travel, and to judge better of its capacities for agricultural improvement. The few remarks which we have to offer, are the result of incidental observations which we were enabled to make on our passage from Newark to Trenton, and from Burlington, through Bordentown, Haightstown, Freehold, Shrewsbury and Middletown to Keyport on Amboy Bay.

New-Jersey is very advantageously situated for marketing the products of her soil. Surrounded, except on her northern border, by navigable waters, with several boatable streams coming from the interior, and two canals and two rail-roads extending from her eastern to her western border, the agricultural productions of the state, may be sent to either New-York or Philadelphia in a few hours, and converted into money; and a great many farm productions, which are perishable, or which would not bear the expense of ordinary inland transportation, are thus rendered sources of immediate and substantial profit. Thus, for instance, the fruits and garden productions of the valley of the Delaware, where the season is earlier than on the Atlantic border, are sent off in the afternoon, by the rail-road, and are in the New-York market the next morning before sunrise, in excellent condition. We returned, a part of the route, in what is termed the *truck* train, which, before it reached Haightstown, or the half-way station, consisted of eighteen cars, filled principally with melons, peaches, and other garden truck. The facilities for transporting lime, marl, manure, &c. are equally advantageous.

The soil of those parts of New-Jersey through which we passed, is mostly sandy, frequently with a tenacious subsoil. The surface in the interior, is gently undulating, but more so near the eastern and western borders; while a ridge, extending from southwest to northeast, may in some parts be called hilly. Many of the lands are consequently too much saturated with water in the spring, and in wet summers, for profitable husbandry. When laid dry, these lands are wonderfully improved by the application of lime or marl, aided by ordinary manures. We were shown a farm of this character, which the present owner purchased a few years since at seven dollars an acre, and which he had since drained, marled, &c. and which was now considered worth $125 an acre. We examined the crops on another farm, and they were fine, which a short time since was purchased for about the same price, and which is now estimated to be worth $100 an acre. It may be still much improved by underdrains and a further application of fertilizing materials.

The defects in New-Jersey farming seem to have been the same as have too generally prevailed in all the Atlantic states:—a system of continued cropping, without regard to draining, manuring or alternating crops. The fact seems to have been but little known, or little regarded in olden time, that plants, like animals, feed and fatten—not upon mere earths—but upon the organic matters in the soil—and that every crop taken from a field diminishes its fertility. Another fault in New-Jersey, as well as in American farming generally, has been spreading the farming capital and farm labor over too broad a surface—in cultivating one hundred acres poorly, instead of cultivating ten, twenty or thirty acres well—the returns and profits of the latter generally exceeding those of the former, of which New-Jersey herself exhibits many notable and highly commendable examples. Draining is essential, in many places, to the healthy growth of clover, in which New-Jersey farming seems very deficient; and, indeed, all grass seeds are too much neglected. We saw several fields which had been cropt with corn and rye, and turned into pasture without grass seeds. We suspect that another defect in New-Jersey husbandry is, the small number of neat cattle which are reared and fattened. In this matter, the Jersey farmers might learn a useful lesson from the neighboring counties of Pennsylvania, where lean cattle are purchased in autumn, and fattened upon roots and coarse grain, for the great markets. They leave upon the farm the elements of fertility to the soil. If the products of the farm are consumed upon it, that is, the hay, straw and roots, and the dung carefully husbanded and applied, the fertility and profits of the farm will certainly, under a suitable alternation of crops, progressively increase.—But if these products are all carried off, and nothing returned, sterility will certainly ensue. Dung feeds crops, crops feed and fatten cattle, and cattle manufacture dung. We have another example to offer to our Jersey friends, of the facilities of enriching their lands. We called upon a gentleman upon the confines of their state, W. A. Seeley, Esq. of Staten-Island, who has a farm of 200 acres, which he has brought into an excellent condition from an impoverished state. His crops were all well manured and fine, and he showed us piles of surplus manure, estimated to contain 2,500 loads, composed of yard dung, peat earth, peat ashes, seaweed and fish, all furnished by his own farm and his own shores. Such is the effect of capital and skill judiciously applied. We will not say we saw the *best* corn growing upon these grounds—but we think we saw *as good* as we saw any where in New-Jersey. The Jersey and Dutton corn were growing side by side; and we are promised a statement of their relative products.

The means of fertilizing the lands of New-Jersey are abundant, the facilities of procuring them great, and a disposition to employ them rapidly extending. We saw near the boatable waters great quantities of lime, marl, green sand, oyster shells, ashes and manure, and in many places marl pits which had been extensively excavated, and were told that the use of all these fertilizing materials was sensibly increasing.

The *Morus Multicaulis* is at present the staple product of New-Jersey, particularly about the cities and villages. On asking a grower near Burlington, what portion of the land in that vicinity was appropriated to the growth of this plant, he replied, between a third and a quarter. Many gentlemen have made fortunes by the sale of the trees and buds, and many, very many, *expect* to make fortunes in a like way, and some by feeding worms. We saw several extensive cocooneries, but principally, at present, appropriated to the production of eggs, which have borne a very high price.—Lands have let for $50 an acre, for raising the multicaulis. There are considerable failures in the crop, owing to the unfavorable spring, the plants having generally been grown from single buds. Actual sales have been made at 15, 20 and 25 cents. We heard of none being sold higher. The plants are from one to five feet high. In Virginia and Maryland, sales are said to have been made at 34, 50 and 100 cents. We saw at Haightstown, many of the multicaulis grafted, at the ground, upon the white mulberry. Their growth had been surprising. We measured some on the grounds of Mr. Coward, which had grown, during the season, 8 feet 4 inches.

Lime is principally brought from Pennsylvania, and sold at 10 and 12 cents per bushel, slaked. It is applied, in rather an effete state, at the rate of 50 to 100 bushels an acre, the poorer land receiving the smaller, and the richer land the larger dressing. It is generally mixed with arable lands by the harrow. Its benefits are palpable; and the increase of the first crop often pays the outlay.

Marl, which includes green sand as well as shell marl, abounds in Monmouth county. That procured from the southern border of the county is deemed best. The expense of dressing an acre at Shrewsbury, with a charge of twelve miles of land carriage, is from $15 to $20. Inferior qualities are procured there cheaper, though a greater dressing of these is required. It amply repays charges in the first crops, and permanently improves the land.

Among other fertilizing materials, we saw *barilla ashes*, and the *fleshings, hair* and *tan* from morocco factories, and great quantities of *sea-weed*, collected on the beach, and afterwards spread in the hog and cattle-yards. Sea-weed forms an important item of manure on the seaboard. We should be pleased to receive a communication, from some gentleman familiar with the subject, as to the best mode of preparing it and applying it to the soil.

Peaches are a profitable article of culture in the country through which we travelled. The fruit is convertible into money in twenty-four hours after it is gathered. The profits would be far greater, if means could be adopted to prevent the early decay of the trees. The average continuance of a peach orchard is from six to eight years; and four crops of fruit are considered a liberal return. The disease which destroys the trees is termed *the yellows*. Would it not be commendable in the New-Jersey State Agricultural Society, which has just been organized, or even in the legislature of that state, to offer a bounty for the discovery of a cure or preventive of this disease? It is preferred by the peach growers to leave the trees without pruning, even in the nursery, that the branches may spread naturally. A Delaware peach grower practises cutting in the branches, after they have borne two crops, and thereby gets newer and better bearing wood. By planting thick, and heading in a portion every year, alternately, the fruit is very much improved, without being sensibly diminished.

The extent of the peach plantations will seem extravagant to some of our northern readers. Many growers have 10,000 trees, one 30,000; and at one place in Shrewsbury, there are 50,000 trees growing contiguous and forming as it were one magnificent orchard.

Melons also constitute one of the staple products of some parts of New-Jersey. Sloop loads are daily taken to the New-York and Philadelphia markets, and sold at ten and twelve dollars a hundred. Some idea of the profits of the melon culture may be formed from data which we obtained at Keyport.

P. Hopkins bought twelve acres of land, in 1837, in Middletown, for which he paid $30 per acre. In 1838, he put four acres in melons; his crop averaged $150 per acre. He put the same in rye in the autumn, and in 1839, got 30 bushels the acre. And in the present year he put six other acres in melons, the average value of which is estimated at $150 to $200 per acre. The expense of lime, manure and fish was $32, and of labor $10 per acre. The account for the two years would therefore stand as below.

Cost of 12 acres of land, at $30,	$360
Cost of manure and labor on 10 acres, at $42....	420
Total outlay,	$780
Receipts from melons, 4 ac. $150 per ac. in 1837,	$600
do do 6 do do 1838,	900
do from rye, 4 acres, 120 bushels,	120
	$1,620
Deduct cost of land and charges,	600
Nett profits in two years,	$1,020

and the land in the bargain.

Green crop of Indian Corn.—N. Shotwell, of Rahway, has made an experiment with corn, as a green crop, which proved highly advantageous, and which, if we mistake not, affords a valuable suggestion to the farmer; as there is probably no green crop which will impart so much fertility to the soil as Indian corn. Mr. Shotwell sowed four acres with corn, broadcast, four bushels to the acre, at the usual planting time. When the corn was about breast high, he ploughed it under, affixing a chain to the whiffletrees, to break down the stalks; at the usual time, he sowed timothy seed, and obtained a greater crop of grass than he ever got after clover, buckwheat, or other green crops.

New mode of preserving Apples.—We were presented by our host, at Trenton, Aug. 10, with a pippin of last year's growth, as crisp, juicy, and of as fine flavor as those we have eaten at midwinter; and on inquiry were told, that they had been kept in a tight cask in an ice-house.

With regard to the state of society in New-Jersey, we are disposed, from the observation we were able to make, to think highly favorable of it. A greater equality seems to exist among the inhabitants, and more good feeling and kind-heartedness towards each other, than is commonly witnessed. All seem to be well off to live; and there are few of those artificial or aristocratic distinctions which are the bane of social and friendly intercourse, and inimical to republican habits and institutions.

Agricultural Geology.

We are indebted to Prof. Jackson for his Third Annual Report on the Geology of Maine, for which we tender him our thanks. We have commenced extracting from it, in to-day's paper, an interesting article on agricultural geology, which cannot fail of being interesting to the enlightened reader. It furnishes another and a strong evidence of the great importance of establishing professional schools of agriculture, as the most, if not the only, effectual means, of learning how to manage our soils, and of developing their hidden riches. The main objection to establishing such schools has been, the want of competent instructors. Do we want better instructors for the scientific department than can be furnished from the geological corps of the several states? And as for practical instruction, we have certainly men enough competent to undertake to give it. And if we had not, the geologists, with their zeal to apply science to this all important business, would soon become practical men. They are now working, hard working men—and many of them would delight in blending science with practice, in schools of instruction. Four years, the period often devoted, in schools, to acquire a knowledge of Greek and Latin, which Dr. Rush says makes learned fools, would suffice to make a young man familiar with agricultural science, to give him the best practical instructions in the art or practice, and to fit him for the highest duties in civil life. And when he came forth from such an institution, upon the broad theatre of active life, he would not be as a light hid under a bushel, but would diffuse spirit, and knowledge, and improvement, all around him.

Among other useful labors which Prof. Jackson has rendered to the agriculture of Maine, is the analysis of fifty-six specimens of limestone, taken from different localities, or quarries. Nearly every variety of limestone found in the state, he burnt in his laboratory, to know exactly how they burnt, the quality of lime that resulted, and the particular purposes for which they were fitted, as for agriculture, mortar, hydraulic uses, &c. These results are given in a tabular form, and show, at a glance, the constituent parts, and the relative value for particular purposes of each specimen.—We will publish in our next, the Professor's directions for constructing lime-kilns, and burning lime, with diagrams of lime-kilns.

Tropical Plants—Spices.

Cinnamon, a tropical plant, growing in the East Indies, and is largely cultivated in the island of Ceylon, where there are more than 16,000 acres in cinnamon plantations. The bark of larger shoots or thick branches is coarse, the finer kinds are obtained from the smaller or more delicate shoots. The best is thin, smooth, shining, and of a light yellow color, bends before breaking, and is splintery in its fracture.

Cassia.—The cassia of commerce is nothing but an inferior quality of cinnamon. The finest cinnamon brings two dollars a pound, the second sort from one dollar thirty to one dollar fifty cents, and the third sort about a dollar. These are the prices in England, where the duties are from twenty-two to seventy-five cents per pound.

Pepper grows on a perennial climbing plant. The leaves are heart-shaped, with a glossy surface, and have little smell or pungency. Small white flowers grow abundantly on all the branches, and these are succeeded by the berries, which are green when young, and become of a bright red when approaching maturity. They hang in large clusters, like bunches of grapes; but the berries grow distinct, more in the manner of currants. It is raised in plantations of 500 to 1,000 plants, divided by hedges. Sumatra and the neighboring islands in the Indian Archipelago, produce the greatest abundance of this spice.

Ginger grows both in the East and West-Indies. It has a perennial root, with annual stems. The roots creep and extend under ground in joints, from each of which a slender stem shoots forth in spring, and attains a height of two or three feet. On the top of the stalk is a scaly spike, from each of which scales a blue flower appears. When arrived at maturity, the root is taken up, and forms the ginger of commerce. It is afterwards ground in flour or other mills for use.

---

* We are indebted for these data to Dr. T. R. BECK, Principal of the Albany Academy.

Nutmeg and mace are the produce of the same plant. It has its male or barren flowers upon one tree, and female or fertile flowers upon another, being a diœcious plant. The flowers are white, bell shaped, and grow at the extremities of the branches, two or three together. The embryo fruit lies at the bottom of the female flower, like a little red knob, which afterwards expands, and at the end of nine or ten months it has the appearance of a peach. The outer coat is fibrous and hard, about half an inch thick; and when arrived at maturity, this bursts, and a membraneous covering of a fine red colour is seen, enveloping the thin black shell which encloses the kernel or nutmeg. This covering is the mace of commerce. The mace resembles a verdant net-work; and, when collected, is left in the shade to dry, after which it is pressed closely in bags and exported. The shell of the nutmeg is hard, and is subjected to the heat of fire before being broken. The kernel thus shrivels up, and is then subjected to the action of lime and sea water to destroy the vegetating principle.

Honey-Dew.

George W. Johnson, in the Quarterly Journal of Agriculture, after enumerating, and, as he supposes, disproving the several theories which ascribes the honey dew upon plants, to insects and to the atmosphere, traces it, we think correctly, to a morbid state of the sap. He says—

> "Heat, attended by dryness of the soil, as during the drought of summer, is very liable to produce an unnatural exudation. This is especially noticed upon the leaves of some plants, and is popularly known as *honey-dew.* It is somewhat analogous to that outbreak of blood which in such seasons is apt to occur to man, and arises from the increased action of the secretory and circulatory systems to which it affords relief. There is this great and essential difference, that in the case of the plants, the extravasation is upon the surface of the leaves, and consequently in proportion to the extruded sap, is their respiration and digestion impaired."

The remedy which Mr. Johnson prescribes for this disease, for such it evidently is, is a solution of common salt and water, applied to a soil in which the plant is growing. For, says he,

> "If we admit that the irregular action of the sap is the cause of the disorder, then we can understand that a portion of salt, introduced into the juices of the plant, would naturally have a tendency to correct or vary any morbid tendency, either correcting the too rapid secretion of sap, stimulating it in promoting its regular formation, or preserving its fluidity. And that, by such a treatment, the honey-dew may be entirely prevented. I have often myself witnessed in my own garden, when experimentalizing with totally different objects. Thus I have seen plants of various kinds which have been treated with a weak solution of common salt and water totally escape the honey-dew, where trees of the same kind, growing in the same plot of ground, not so treated, have been materially injured by its ravages. I have noticed that standard fruit trees, around which, at the distance of six or eight feet from the stem, I had deposited, at the depth of twelve inches, a quantity of salt, to promote the general health and fruitfulness of the tree, according to the manner formerly adopted to some extent in the apple orchards of cider countries, that these escaped the honey-dew, which infected adjacent trees, just as well as those which had been watered with salt and water. I am of opinion that one ounce of salt (chloride of sodium,) to a gallon of water is quite powerful enough for the intended purpose."

Economy of Fuel.

We published in our second volume an abstract of Dr. Bull's experiments with fuel, showing the quantity of heat produced by the several kinds of wood and coal, with many other facts of interest to the buyer and seller. Of Dr. Bull's work, Prof. Silliman remarked, that it was "one of the most important contributions of science to the arts and domestic economy, which had been made in a long time in this country." Mr. WILLIAM YATES, of Troy, has just published, on a broad sheet, a "Guide to economy in Fuel," in which he has comprised in a tabular form, the result of Dr. Bull's experiments, and added a scale of prices, which shows at a glance, the relative value of the different kinds of fuel, and which will enable the purchaser to decide correctly which it is the most economical for him to buy, at the market prices. Say, for illustration, that if hickory wood is $8 the cord, the relative value of other kinds of fuel are as follows: White oak $6.88, white ash $6.54, white beech $5.52, hard maple $4.80, white elm $4.64, soft maple $4.32, button wood $4.16, pitch pine $3.65, white pine $3.59, Schuylkill coal $7.79 the ton, Lehigh $7.48, Lackawana $7.48, Rhode-Island $5.41, Worcester $4.46, Liverpool coal $18.27 the 100 bushels, Richmond coal $17.42, hickory charcoal $14.11, maple $9.69, oak $9.01, pine $6.37, &c. &c. The scale is graduated for the prices of hickory from $6 to $12 a cord. The table will be of great use to every buyer of fuel, who wishes to study economy in his purchases of this article, and is for sale at the bookstores. It should be recollected by the seller, that wood, upon an average, loses 42 in 100 lbs. by drying. Hence the disadvantage of taking green wood to market. And the buyer should remember, that he loses 13 per cent of the value of his wood by burning it when green. See vol. ii. p. 122, Cultivator.

Sowing Evergreens.

A correspondent on Rock River, Ill. writes us as follows:—"In the month of April, 1838, I took about half a bushel of Red Cedar seeds* to my garden, poured them down, and mixed them with about four bushels of earth. This pile I mixed up and turned over four or five times during the summer. In April, 1839, I planted these seeds, dirt and all, in drills; every seed vegetated, and came up as well as wheat. Many of the plants died by the dry weather, but millions were growing finely in July.

"The white cedar (*Thuya orientalis,*) seed, sown in the fall, vegetates and comes up the following spring." This tree is usually called the Chinese arbor vitæ, and differs somewhat from the American species, best known by the name of white cedar. The American species grows to the height of 45 to 50 feet, has a beautiful foliage, and the timber is valuable for a great many purposes. The seed may be obtained in any quantity, and would be a valuable acquisition to the prairie west. The tree likes a moist cold soil.

* Probably cones, containing seeds.

Crops, &c. in Virginia.

A correspondent writes from Columbus, Va. July 29: "Our crops in this section, (Fluviana county, in the valley of James' River,) are chiefly corn, wheat and tobacco, which are cultivated on the three field rotation. Thus corn or tobacco, wheat and a year of rest in clover, applying our manure in the spring to the corn or tobacco crops. The wheat crop just harvested is an inferior one, in quantity and quality, having been much injured early in the spring, by the Hessian fly, and afterwards more seriously attacked by swarms of the chinck-bug, together with rust in the late wheat, gave the crop the 'coup de grace.' Great apprehensions were entertained for the corn crop, from the swarms of the chinck-bug, which have always been one of its worst enemies; but they have fortunately passed off without much injury to it. The corn and tobacco crops are unusually promising."

Another letter, dated Greene C. H. July 15, says:—"The crop of wheat in this section, I do not think an average one. Oats and grass very heavy. Clover of last spring's sowing failed, owing to the drought. Corn very promising at this time."

A New Implement,

Which promises to do the work effectually of a subsoil plough, taking only *half* the draught, and stones being little or no obstruction to it, has been announced in the Quarterly Journal of Agriculture, by Lawson & Son, as having been invented by a shoemaker. It is simply a heavy metal wheel, of about five feet in diameter, with slightly curved iron spikes or teeth inserted in its broad rim. It is drawn by a pair of horses, while a man steadies it behind with a pair of stilts, similar to those of a common plough, the which is fixed in a frame similar to that of a roller, but without support on either side. Messrs. Lawson suggest, that a pair of light wheels might be added with advantage, as tending to relieve the man considerably.

Furrow-Draining.

This modern mode of improving lands is coming into extensive use in Scotland, as will be seen by the following quotation from the Quarterly Journal of Agriculture.

> "One cannot go a distance from home without observing the extent to which furrow-draining is now practised. Almost every stubble and grass-field that is intended to be ploughed up, especially at the commencement of a lease, presents, by cuttings, stones and tiles, a pleasing scene of industrious enterprise, and of determined desire of improvement. At some places drains are cut in every furrow, [between the ridges,] from 15 to 18 feet asunder, at others in every other furrow, the distance no doubt, being regulated by the nature of the subsoil. Stones are entirely used in some places, but, in general, we should say, tiles alone are used, though in others, stones are used in conjunetion with tile. This last mode is perhaps the best for filling drains, and is certainly preferable to tiles alone; but where stones are really scarce, much rather use tiles alone than neglect draining."
>
> * * * "We are too apt to argue as if the properties of thoroughly drained land remained the same as undrained.—It is difficult to find an object to compare land with; but we may compare undrained land to a sponge containing a considerable quantity of water; a small addition to which makes the sponge overflow, and it is ever ready so to do. Drained land, on the other hand, may be compared to a sponge recently squeezed out and dried on the surface, which is ever ready to receive a considerable quantity of water, without making much difference on its appearance. Thorough-drains become almost dry in a few years; nevertheless, they are in constant requisition, and, but for them, water would be retained in the soil; but they are only completely tried as water-runs after heavy rains. Thorough-drained land may be laid perfectly flat, in which case water enters the drains from every quarter."

Economy of Power.

There are a great many operations on the farm which may be economically performed by a stationary power, that is, by water, by wind, by horses or oxen, or by steam. The same power that is applied to the thrashing of grain, or to the grinding of apples, may, if properly adjusted, and with a trifling additional expense, be applied to the crushing of grain for farm stock, or even grinding it for family use—to the cutting of hay and straw—to the sawing of wood, slitting boards, &c.—to turning the grindstone, pumping water, and various other stationary uses. A friend, whom we visited on Staten-Island, applied, he told us, his wind-mill, to either fourteen or eighteen different purposes. There is no doubt in our mind, that a vast economy of human power is capable of being made, and will be ere long saved, by a stationary power about the farm buildings. The thrashing machine is an indication of what may be done, in other branches of farm labor, in economizing time and money. A stationary power which can be applied to the various operations of the farm and out-buildings, must be a desideratum with every farmer, whose business is on any thing like an enlarged scale.

The Highland Society of Scotland, fully appreciating the importance of determining the most economical power to be employed in propelling the thrashing machine, offered a premium for the best essay upon the subject; and Mr. Robert Bridges became a competitor for the prize. In discussing the merits of the different moving powers, we find some data which, though not exactly adapted to our practice, are nevertheless worth recording in the Cultivator.

1. Mr. Bridges estimates the expense of a substantial *water-wheel,* including mason-work of fall or mill-race, from £70 to £110—average £90; reservoir, water course and tail-race, say £150.

2. The cost of erecting a *wind-mill,* of the best materials and construction, including tower, at £350.

3. The expense of a *horse-wheel,* including the building to cover it, at £120; and the annual expense incurred by a pair of farm-horses, taking the average of half a dozen estimates of the best authorities, at £112.7.7. And that,

4. A four-horse power *steam-engine,* on the high pressure principle, which Mr. B. considers sufficient for farm purposes, will cost £110; engine house and chimney about £70; making a well from £5 to £7.

The cost of the several powers, including 10 per cent on the outlay, and the expense of driving them 42 days, the estimated time of thrashing yearly, are stated as below.

Water Power—Cost,..................		£240	0	0
	Yearly expense, inc. int..	30	0	0
		£270	0	0
Wind Power—Cost,..................		£350	0	0
	Interest and attendance,..	39	4	0
		£389	4	0
Horse Power—Cost,..................		£120	0	0
	Yearly expense,........	130	17	7
		£250	17	1
Steam Power—Cost,..................		£187	0	0
	Yearly expense,........	33	18	6
		£220	18	6

Mr. Bridges draws the following inferences from his estimates.

1. That water, where it can be obtained, is the cheapest moving power that can be applied to the thrashing machine; and that the advantage, in point of economy, is so obvious as to warrant the outlay of a much greater sum than that specified in the comparative estimate.

2. That next to water power, steam is the cheapest and most economical; and, in absence of a sufficient supply of water, nothing but the total want, or high price of fuel, can prevent its universal adoption.

A Horticultural Exhibition

Will be held in Albany on the 18th of September, at which prizes will be awarded for the finest flowers, fruits and vegetables, and the competition unlimited. There are five dahlia prizes, of 20, 15, 10, 5 and 3 dollars, to the exhibitors of 25 flowers. A like exhibition will be held at Philadelphia on the same day, and at N. York on the 12th.

Clayed Maple Sugar.

We have received from Henry Muzzy, of Rutland, Vt. 10 lbs. of maple sugar, of very superior quality, equal to sugar which sells at fourteen to sixteen cents per pound in the cities. Mr. Muzzy is a competitor for our premium for the best sample of this domestic sugar. We would hope to have many *such* competitors. By the bye, will Mr. Muzzy be so kind as to favor us with his mode of manufacturing and refining the article, with the estimated cost, for the benefit of sugar-boiling customers?

Pitt's Thrashing Machine

Is highly commended in the American Farmer, by R. I. Jones. He states, that in the presence of his neighbors, he got out in fifteen minutes, ten bushels of wheat, "as clean as could be done by passing it through the fan three times, if got out in the ordinary way." He also got out in 4¾ days, 1,081 bushels of wheat, and 336 bushels of oats, making an average of 240 bushels per day. The wheat was so thoroughly cleaned in the process, that it brought three cents per bushel above the market price. See our account of this machine in our Feb. No. of 1839, and Oct. No. of 1838.

Agricultural School Books.

There are two works in the course of publication, which we hope to see published in volumes, and introduced as class books for the senior boys, in our common schools. They will effect more, in inculcating a taste for rural pursuits, and in advancing the substantial interests of the commonwealth, than all the English Readers, Columbian Orators, and such like books, which now constitute the popular class books of our common schools. We want more working, and fewer idle men. Teach the young, that they can find profit and honor, and happiness in rural pursuits, and they certainly are to be found there in a greater measure than any where else,—the producing classes will be increased—the state will be correspondingly benefitted, and we shall be exempt from those commercial panics which periodically convulse the nation, and which may now be inflicted upon us at any time by our European creditors.

The two works to which we allude, are, first, "*Dictionary of terms used in agriculture, and in the sciences most intimately connected with its advancement,*" published in the *Genesce Farmer*, and written by Willis Gaylord, Esq. The *second* is "*Early lessons in scientific agriculture, or conversations on agriculture and the subjects connected with it, intended for the use of young men in and out of school.*" This is now publishing in the *Franklin Farmer*, and is said to be written by a Mr. Lewis, brother of the late Meriwether Lewis, but, at all events, a gentleman of an enlightened and useful mind.

Short Horned Cattle.

Eleven short horned cattle, ten cows and a bull, passed through our city a few days since, on their way to Kentucky. They are described as first rate animals. They were purchased under the direction of Lord Althorp, in England, for Henry Clay, Jr. of Kentucky.

THE BUDGET.

Millers' Tolls.—This subject has degenerated into a personal controversy, of little interest to our readers. Our determination to publish nothing further on the subject, we hope will be approbated by our respectable correspondent, if he will for a moment divest himself of personal feelings.

Carbonate of Lime as a dressing for land.—We have a communication from Mr. Joseph Warbasse, of Newton, N. J. who has been in the habit of applying to stiff clays a dressing of ground limestone, of a soft kind which abounds in his neighborhood, with very good effect. Mr. W. we believe, is a very good farmer, and has represented correctly the beneficial effects of the carbonate of lime upon his clays; but his philosophy is of the by-gone age. Carbonate of lime benefits clays by rendering them more porous, and consequently relieves them in some measure from surface water, but it will not render wet clays dry, without draining. It improves its mechanical texture, and adds to its chemical powers, and therefore promotes fertility.

Buckwheat Straw.—A Herkimer correspondent inquires in what manner buckwheat straw must be saved to render it good food for neat cattle? We cannot answer him from experience, as we do not cultivate buckwheat. But we have no hesitation in saying, that buckwheat straw, when intended for cattle food, should be saved with the like care as hay or corn stalks, that is, dried so that it will not heat and mould in the mow or stack, with the least possible exposure to rain and dew. The stalks being very succulent, we think the curing can best be effected in small heaps, or cocks, in the field, before the grain is thrashed.

Queries.—Mr. J. Robinson, of Marbletown, asks us several questions—as how he shall prepare his ground for wheat? How to rot his flax? If he had better put lime in his compost? If liming seed wheat will preserve the crop from insects? Whether seed wheat is best covered with the plough or harrow? &c. We have stated our opinions, and given directions on all these matters, in our previous volumes, so far as related to general practice, and we must refer to them for answers; for Mr. R. must be sensible of the impropriety of our repeating what we have recently published. But we will summarily observe, that his wheat ground should be *well* prepared, that is, made clean, and fine, and rich, by the compost he is preparing as a top-dressing; that his flax should be water-rotted, as directed in the Cultivator, vol. iii. p. 193; that a small portion of lime will benefit his compost; and that wheat may be ploughed shallow, or harrowed in, as the soil is heavy or light, wet or dry, the light or dry soil requiring the most covering—the object being to cover all the seed, as near the surface as can be to secure a healthy germination and growth.

Italian rye grass.—Mr. Benfoot, Richmond, Va. can obtain seed of Italian rye grass, of Thorburn, or Smith, or Weaver, seedsmen, New-York, at least in time for spring sowing, which season is to be preferred for sowing it. It may be sown precisely like other grass seeds, broadcast, by itself or with other seeds, and harrowed or bushed in.

"*Medicus*" will, on reflection, see the impropriety of answering his *special* inquiries through the Cultivator, inasmuch as our readers would not be likely to be profited by our answers, and he has not given us the opportunity of anwering them by letter. In regard to the corn, nineteen-twentieths of which was pulled up by the crows; a recurrence of the evil may easily be prevented by simply steeping the seed, and then mixing with the steep some tar dissolved in hot water. We are sure the crows will not eat it.

CORRESPONDENCE.

Diseases of Sheep.

Mr. Cultivator—In your May number, there is a letter from Lewis Bailey, of Fairfax co. Va. who desires information respecting the cause and cure of a peculiar disease which had attacked his sheep. From Mr. Bailey's description of the disease, I should infer that it was an inflammation of the brain, caused by confinement and bad air, which, it is well known in the "old country," will produce symptoms similar to those he mentions.

The following is the common and usually successful method of treating it in Great-Britain:—Two ounces of castor oil are given to each animal, and its head washed with spirits of hartshorn, or (as some prefer,) cold vinegar and water; and if affected with blindness, it is bled in the veins which run from the corners of the eyes towards the nose. Until recovered, the sheep are not allowed water, but supplied instead with as much strong green tea, sweetened with molasses, as they will drink. Of course, in order to ensure success, they must have roomy pens and plenty of air.

A SCOTCH PLOUGHMAN.

Mildew—Root Culture.

In looking through vol. iv. p. 159, of the Cultivator, my attention was drawn to the comments of the conductor on an article headed "Mildew on Gooseberries and Grapes." The comments are based on the theory, that mildew is produced by a parasitic plant. If this theory be correct, it *will* or *ought* to apply to wheat and other grain. Facts,* reason and observation certainly go far to prove this theory fallacious. Mildew on wheat cannot be traced to the same cause, because the effects would disprove the cause. Were it occasioned by the parasite, the disease would be gradual and could be noticed in its progress, while on the contrary, it is known to be sudden, the effect attending the cause. One year ago, a farmer of my acquaintance had a beautiful field of wheat, which he examined in the morning, and found the grain had nearly approached the dough state, and the straw had a bright, healthy appearance. Being absent through the day, he found to his great surprise, in the evening, that his whole field was "struck with mildew," the straw much affected and discolored, entirely disappointing his hopes, in a single day. The grain weighed only forty pounds per bushel; the maturing process having been suddenly arrested. It is presumed, the wheat was affected the preceding night, and the effect was made visible by the sun's influence the following day, something like frost. Flat and low grounds are most liable to mildew, while those elevated and undulating escape. My opinion is—although there may be a combination of causes—yet in the main, it must be attributed to atmospheric influence, instead of the parasitic plant. The critical period is about the time of full moon, a fact not unsupported by philosophy.

Root culture has fairly commenced in this vicinity—our farmers are making large calculations in relation to its benefit. The early season was full wet and cool, which prevented the beets from vegetating well. The sugar beets prevail at present, but I expect to see the farmers give mangel wurzel the preference, when they shall have acquainted themselves with the diuretic character of the sugar beet. Mangel wurzel possesses also the important advantage of keeping longer and better. The vernacular name of this root being still preserved and perpetuated, I was amused to see the honorable conductor attempt, in a late number of the Cultivator, to translate pure German into English: "mangold," according to the translator, signifying "beet," and "wurzel, root, beet root." The conductor is unsparing occasionally of sarcasm and strictures with the correspondents of the Cultivator; so I hope I shall be pardoned for the censorial notice I have taken, either of his theory of mildew, or his German and English translation. Mangel signifies scarcity, making the literal translation scarcity root.†

We have just finished a very abundant harvest.

W. PENN KINZER.

Spring Lawn Farm, Pequea, Lan. co. Pa. July 27, 1839.

The Peach Tree Grub—The Bee Moth.

Jackson, Tenn. Aug. 16, 1839.

Judge Buel—Dear Sir—I have noticed in your valuable paper several things recommended to destroy the grub in the peach tree; but from the experience I have had on the subject, I have seen nothing recommended, in my opinion, to cure the evil. Being myself fond of good fruit and raising fruit trees, I have for the last five years paid particular attention to the movements of the grub on the peach tree. I first discovered, during the summer and fall, in and under the glue near the roots of the tree, small knots of worms of different lengths, with a black or brown head. After making this discovery, the next winter and spring I commenced cutting in with a knife at the place I found they had entered the bark, and frequently found them eating under the bark of the root; and in taking up small trees to set out in the spring, I made it a rule to take a knife and follow them from the place they had entered, and would frequently find them under the bark, five or six inches from the place of entrance. After making this discovery I commenced clearing round the trees during the summer and fall, leaving the tops of the roots naked; and put round them fresh dry ashes, and sometimes tan from the tan-yard. This I found to be of considerable benefit in destroying the young grubs before they entered the root. Wishing to ascertain at what time the grub changes or leaves the root, I commenced an examination at different times during the spring and summer, and on the 20th day of August last, I discovered a a great number had come out; and under almost every place where I found old glue at the surface, and from that 1½ inches under ground, I found the grub encased, sticking to the root of the tree. I found some of the grubs had changed and left the encasement; and at those trees I found a black, slender looking bug which seemed to be cutting the bark near the surface; and at those trees I found fresh glue and small young grubs. I then had all the grubs destroyed, the trees cleaned round, and fresh ashes put round some and tan round others. This year I commenced my examinations the 1st June; found no grubs out encased: on the 18th July I discovered a few; and up to this time I have not found more than 1½ doz. on from 55 to 60 trees. Last summer I had several old trees which appeared much on the decline; leaves yellow and fruit small; this season the leaves look well and fruit very good.

I saw last year recommended in your paper to plant peach trees in the yard so that the fowls could destroy the grub: this, I believe, will not answer, unless the grass, &c. is kept from about the roots; as the first grub discovered by me encased was on a tree in the yard, where the fowls had free access. I have taken up at different times peach trees on the decline, and found that the decline of the tree goes on in proportion to the number of grubs and the distance they have cut round the root. Some trees planted at the same time die earlier than others; this is owing to the number of grubs first deposited; the greater the increase, the sooner they cut round the root. From the discoveries I have made of the grubs, and the different experiments to destroy them, I am now fully convinced the better way to destroy them is while they are encased and about to change; and while the young grubs are in the glue before they enter the bark. Last spring I raised the earth a little on the roots of some of my trees, which I found an advantage in getting at the grub while encased, as they will approach near the surface; when the earth is raised and light it is very easy to get at them. I had concluded to send you in a newspaper which will go by this mail, four of the grubs incased, and two of the bugs, which you can examine. I think it likely by the time this reaches you, it will be a good time to examine for them in your country.

I see from your paper the bee moth is very troublesome in your section of country. When I commenced house keeping, I purchased a few stands of bees and the moth destroyed them all the first year. Upon examination, I found that the moth deposited the eggs in a web between the bench and the box: and as soon as they hatched they crawled up to the comb, and formed a web round them so the bees could not destroy them. I made it a rule to go to the stands two or three times a week, and brush off the eggs and web deposited; but finding this troublesome, I concluded to raise the boxes by putting small wedges under each corner: this I found of great service; but I discovered, unless the wedges were made very smooth, the eggs were frequently deposited under the wedges. I then concluded to drive a ten-penny nail into each corner and let the box rest on them, so the bees could pass under all round. Since I adopted this plan which has been twelve years, I have not, as I recollect, been troubled with a single bee moth. I am not in the habit of writing any thing to go in a newspaper,—but if you think the experiments I have made will be of service to the public you can publish them. Very respectfully your ob't servant.

SAMUEL LANCASTER.

Various matters considered.

Dear Sir—A few days ago one of our most respectable physicians came into our store, opened a volume of the Cultivator, and read the communication of mine, saying that bots never injured the horse. He then remarked with emphasis, that he had seen the maw of a horse where the bots had eaten through it, the evidence of injury and consequent death of the horse. I answered, that in my view, it was evidence of another fact. That when the horse was dying and dead, his maw became cold and uncomfortable to the bots, and they would "go ahead" by perforating the maw, to escape from the cold. I asked if he had seen parasites crawl from animals soon after their death, to escape from the uncomfortable cold? That head lice run over the face of the human subject, after death, when the head becomes cold. He left us abruptly, without answering.

On reading the remarks of your scientific correspondent, J. M. Garnet, in favor of applying manures to the surface, rather than ploughing them under: I ask, whether the value of his experiment of spring ploughing over that of autumn, is not to be attributed to the warmth the surface had received from the sun, together with looseness and mellow state of the ground, thereby admitting more air and rays of the sun, and rain, to promote the chemical action of the manure, which also had become warm from the sun?

---

* The "facts and reasons" of our correspondent go rather to confirm, in our opinion, than to disprove our theory, that mildew is a parasitic plant. Had the state of the atmosphere been noted when the wheat crop of his neighbor was struck with rust, we presume our correspondent would have described it as humid, hot and light, which is that condition, and perhaps the only condition, in which the seeds of this parasite are wafted on the "wings of the wind," attach themselves to the stems of plants congenial to their growth, and feed upon their juices. If the mushroom springs up in a night, is it at all strange that the minute plants of mildew should grow to maturity in a few hours? There are innumerable animalcula, whose figures cannot be discerned without the aid of a magnifying glass; and there are innumerable parasitic plants, whose seeds escape our observation. And if mildew is not a vegetable, we beg to ask, what is it?

† Loudon spells this root *mangold wurzel*, and gives the derivation of the term, which we adopted from memory.—*Scarcity* is the name of a *species* of the *beet* family. Our error consisted in translating mangel wurzel *beet root*, instead of *scarcity* beet root.

We invite, on all occasions, liberal criticism. It is the collision of flint and steel that elicits light.—*Cond.*

Many farmers think fall ploughing best: others plough in the fall to forward their spring work: and others, who have tried it, think fall ploughing very injurious. I am not a farmer, and cannot give experiments. What I say on the subject is theory and observation.

It has been the practice of some farmers to make a dung heap, and let the dung rot for a year or more, before applying it to the land. Such manure retains all the earthy part, which I suppose the least valuable, and is in a delightful state to breed and feed grubs and other worms, to be carried with it into the field, and feed on the young plants. The grubs could not live in the early dung heap, while the heat and caustic gases are let loose by chemical action, causing the decomposition.

My observation has induced me to believe, that all manures produce their greatest effect on vegetable growth, when decomposed under the surface of the ground. Heat and moisture are the great moving causes of vegetation, and promote vegetable and animal growth. Without heat, we and every thing would be as adamant, as marble. All organized matter is hastened in its decomposition by chemical heat. The heated gases let loose during decomposition, I conceive, are good nourishment to, and great promoters of, vegetable life. The coarsest manure, even new straw, if ploughed under, will probably furnish the most nutriment, and best for Indian corn and potatoes, for the first season, and leave all the value of the manure of the dung heap for the next year's nutriment for wheat, and other vegetables or small roots,—so that the whole value of vegetable manure is obtained by ploughing under the coarse manure, and nothing is lost: which I suppose is nearly twice as much as when rotted in the dung heap; and more than when left on the surface of the ground.

I suppose that double the usual quantity of potatoes may be produced on an acre as are ordinarily raised, (particularly on alluvial ground, where the soil is rich and apt to pack hard,) by ploughing under so much as can be covered by the plough of coarse vegetable manure; even pea and rye straw, if the ground be ploughed deep and in narrow furrows, to make it perfectly fine and loose. The coarse manure keeps the ground loose, and enables the roots to extend,—retains moisture, so necessary to the growth of potatoes; and the gases let loose, stimulate the plants to vigorous growth. If these remarks meet the approbation of some farmers of liberal views, who believe that some improvements may yet be made in agriculture, I hope the experiment may be made, and reported in the Cultivator. By this mode of culture, I suppose the greatest possible produce of potatoes may be had.

Man is called a reasonable being, and he is so: that is, he has the faculties of reason given to him, and yet there exists not so unreasonable an animal as man. I stated to you in a former communication, the manner of the great gifts of the Creator to man above other animals, in improving the volume and faculties of the brain after birth: yet man, with all these gifts and faculties, is guilty of the greatest aberrations from duty, by omission and commission, in disobedience, in idleness and obstinacy, in refusing to cultivate and improve them.

What a wonderful and heinous crime was committed by our first parents, so to offend their Maker, as to entail so many and so painful diseases and death on all their progeny, even the innocent and amiable little cherubs of infancy and youth! It was disobedience. As we shall have to account for all these gifts and faculties, let us be obedient and active in their improvement, to the honor of the great donor, and our own profit; and not say *we have no time*, and that there is no improvement to be made, like the servant "who rolled his talent in a napkin and buried it in the earth."

We despise the reptile and little insects, because we are too indolent in observing their obedience to the Great Spirit, who whispers his laws to their inward ear; and how strictly they obey by industry and improvement of the talents committed to them.

See the little despised caterpillar, in her winged state, not carelessly depositing her egg for her future progeny, on a fence, the ground, or even on the trunk of the tree on which it is to feed, when called into active life in the future spring. No, with more skill than man ordinarily uses, she seeks a suitable tree, and deposites her eggs on the twig, near to a bud, where the leaves must shoot out by the genial warmth of the vernal sun, a little before it has wakened the egg into active life, ready for its food. Can she do any thing with more design and intelligence? So the honey bee builds its cell for the deposite of the honey, its food, and birth place and cradle of its future young, with the greatest possible economy for strength and space. No shape but the hexagon can furnish the greatest and most useful space and strength of structure. The bee has not to learn this by apprenticeship; its faculties are complete at its birth. They are natural mechanics, of the highest order, and all the workers understand and apply their labor alike. So the little mason bee, after perforating the hard cemented wall, to deposite its eggs, adds a store of food, and then closes the cradle with a door of moistened clay, to shut out enemies. The food is deposited with as much design, and probably intelligence, as man provides for his offspring, because the insect knows its young must feed while a helpless nymph or aurelia. You call this instinct. What is instinct? It is the knowledge of the law given by the Great Spirit, and obedience thereto. Would to God than man cultivated his faculties so industriously, and obeyed so faithfully and certainly.

These evidences in the insect family show their strict obedience to the commands of their maker; yet a mistake or interruption by man, or other means, may be fatal to them; as their faculties are complete at birth, they have not the gift of reason and reflection to improve and repair damages, as reasonable man can; and they will not be called to account for that which was not committed to them.

Should rational man alone be guilty of wasting such precious gifts in idleness? No, man, to whom much has been given, of him more will be required.

The Good Spirit has bestowed on him greater powers of intellect, with wonderful faculties of reasoning and improvement, that he might be constantly employed in providing sustenance for himself and family. Most judiciously given, that he should not be idle. And enough is given, that he should not say that he has no leisure to contemplate and worship the giver with gratitude and joy. There is no age nor state of man, when he can say there is nothing more to be done or learned.

Being desirous of improving the agricultural interests, and believing your Cultivator to be eminently calculated to aid that laudable object, I have accordingly given you some of my cogitations. I am a merchant, and if I have an interval from business or conversation of three minutes only, I take a book or a pen, and never waste a fragment of time. As cents added make dollars, so minutes make hours. My offerings to you are a sacrifice, and not the product of leisure. I offer them as a setting pole to you in your arduous duties. When I write what you judge may not be of relief to you, nor of use to the public, cast them under your table. Most respectfully, DAVID TOMLINSON.

Schenectady, Aug. 14, 1839.

How to pickle Tomatoes.

Pickle tomatoes in September, when they are just ripe (red.) Put them in layers in a jar with garlick, mustard seed, horse-radish, spices, &c. as you like; filling up the jar; occasionally putting a little fine salt proportionably to the quantity laid down; and which is intended to preserve the tomato. When the jar is full, pour on the tomato cold *cider* vinegar, (it must be pure) till all is covered; and then cork up tight, and set away for winter.

DAILY USE OF THE TOMATO.

1. Cut up with salt, vinegar and pepper, (as you do cucumbers) and eat away as fast as you can.

HOW TO STEW TOMATOES.

2. Take your tomato from the vine, ripe; slice up; put in a pot over the fire without water; stew them slow, and when just done put in a small lump of fresh butter, and eat as you do apple sauce. What you have left, put away in a jar for winter.

3. When stewed, beat up half dozen fresh new laid eggs, the yolks and whites separate; when each are well beaten, mix them with the tomato,—put them in a pan, and heat them up; you have a fine tomato omelet. C.

Remarks on the Grain Worm.

Princeton, Schenectady co. August, 1839.

Mr. Buel—Dear Sir—The early sowed barley has suffered more than usual this season, from the ravages of the grain worm, which may be owing to the fact, that there was very little grain of any other description, in this vicinity, in a proper state of forwardness at the time the parent fly made its appearance. There was no winter wheat sowed. Rye was beyond their reach, and spring wheat, except a few pieces, too early sowed, had not yet headed out. The early pieces of spring wheat have been much injured. It is worthy of remark, that in the immediate neighborhood of fields on which winter wheat was raised last year, (and of course destroyed,) the destruction is much greater this season, than it is generally in other places. The fly seems to prefer the wheat to every other kind of grain; it never escapes if in a proper state for their purpose. Rye is their next choice—then barley when neither of the others can be obtained. As far as I know, the grain worm has not yet been detected in any other kind of grain than the above. The experience of several years has taught us that the injury to spring wheat will be avoided, if not sowed sooner than the 15th or 20th of May, and that a good return may be realized. Rye, if sowed early, on land in good condition, will also escape, if it has not, from some cause, been retarded in its growth. The two-rowed barley, likewise, by delaying the sowing for a short period, will be out of the time of the fly; it is the early sowed only that is injured. I think the four-rowed, if sowed early, will escape—at least I have never detected the grain worm in it. Would it not, then, be well for our farmers, as far as the grain worm extends, to sow only such kinds of grain, and those kinds at such a time as will insure their escape from the ravages of that insect? Were such a measure simultaneously carried into effect, I have no doubt but that, in a short time, the grain worm would either entirely disappear, or become so reduced in numbers that their effects would be little observed.

When propagation ceases, the species whether animal or vegetable must soon become extinct. Now certain grains in a certain state of forwardness must be ready for the *parent fly* to deposite its young, which grain is the aliment of the grain worm for a time, and if these can by any means be withheld, it is reasonable to suppose that the propagation of that insect will be much diminished. Man has control over the increase of many animals, and this extends even to some of the insect tribes. The silk worm cannot propagate if the proper food is withheld, neither can those vermin who multiply in filth or putridity, when the cleansing process deprives them of their natural aliment, and I do not see why the increase of the grain worm may not also be kept in check on the same principle. If you conceive the above observations to be pertinent, you are at liberty to make such use of them as you think proper. Your opinion is respectfully solicited, as to the practicability of effecting, and probable result, if effected, of such a measure. I am, dear sir, yours respectfully,

JAS. SMEALLE.

Remarks on Farm Dwelling Houses.

Judge Buel—Perceiving by the number of the Cultivator for the 1st of August, which has just reached me, that you propose inserting in the number for the 15th, essays and diagrams on "Farm Dwelling Houses," I would draw your attention to the remark of Mr. Sedgwick, in part first of his "Public and Private Economy," that "we have no good farm houses in America, and that he would be a public benefactor who should furnish a plan for general use." The English are too ornate and expensive; implying cheapness and subdivision of labor, and long tenure; the Americans are too large, ill contrived, and regardless of proportions, commenced on too large a scale, and never finished, or even if finished, most of the rooms kept for show, not use. It is bad enough where there is but one room, to sit, cook, wash, eat and sleep in that one room; but it is still worse to do so, as is very customary among our farmers, when you have a number of other rooms unoccupied. Nothing can be more ludicrous than to approach a house with lofty Corinthian pillars in front, and then enter by a back door, and find the whole family huddled together in the kitchen.

The only branch of the fine arts with which we really have any thing to do in this country, architecture, is sadly neglected. Would not articles upon the subject, particularly upon domestic architecture, come within the scope of your journal, and be of great benefit to your readers?

After fitness, convenience, and comfort, comes ornament—and the only ornament necessary in a farm house is that which is never considered, to wit, *proportion.*—With it, a house may be beautiful, though perfectly plain—without it, all the ornament in the world will but make it an object of ridicule to correct taste.

Intending to build a farm house shortly, my object however is to avail myself of your proposed publication, and with this view to inquire, what are the advantages of stone? Would not one story houses be better than two? Is it not advisable to dispense with chimnies altogether? And do we not have too many small windows instead of a few double windows, opening in the middle up and down? MOHAWK.

The Silk Business.

J. Buel, Esq.—Dear Sir—You are aware that I am strong in the faith, that this country will ere long, not only supply her own wants in the article of raw silk, but have a large surplus for Europe. You are also aware, that I have given much attention to the subject; in fact, have devoted my whole time to it for the last nine years, and that I have plantations for making silk, and factories for working it, and that thousands are now engaged in the same pursuit. Well, sir, notwithstanding all this, we have daily accounts of persons, who assert that the whole affair of silk culture is a "Humbug." Almost every paper I take up, has something of the kind, intimating that all the excitement on the subject at present, is merely for the sale of trees, "speculation," &c. and advising all within their influence to have "nothing to do with it"—that "we cannot raise silk in this country, and that it is preposterous to think of it." May I ask you, sir, to permit me the use of your columns to discuss the matter with any or all who make those assertions? My object is, to have the question settled beyond a doubt, and if any of the doubters will favor us with the grounds of their unbelief, in our ability to raise silk, or that we shall not in ten years, supply our wants, at least, from our soil, I pledge myself to examine the subject fully, and if I cannot answer them, will confess that I have been deluded and have deluded others into the belief, that *we can raise silk on all our farms, amd to more profit than any other agricultural production; cotton not excepted.* I will now assert that we can raise silk *cheaper than France or Italy*, in any part of our country from Maine to Mexico, of a *quality equal to any in the world;* and shall esteem it a favor to all who are engaged in the business—in fact to the country at large, if any of your numerous readers, will, in reply to this, state *why* we cannot do it, or if they cannot refute the above, then *why* we shall not seriously engage in the cultivation of raw silk for exportation. SAMUEL WHITMARSH.

Northampton, Mass. August 8, 1839.

SOUTH-DOWN BUCKS.—Two two year old very superior South Down Bucks, clothed with fine wool and long enough for combing, were imported last April, direct from England, from the flock of the late John Ellman, Esq. of Glynde, near Lewes, Sussex, and are for sale at one hundred dollars each, or to be let for the season at fifty dollars each, by the personal friend of the breeder.

Elizabethtown, N. J. Aug. 20, 1839. OB. ELLIOT.

☞ The Genesee Farmer and Farmers' Cabinet, will give the above two insertions, and send bill to advertiser.

EXTRACTS.

Agricultural Chemistry.

BY HENRY R. MADDEN, ESQ. L. R. C. S. EDINBURGH.

[*From the Edinburgh Quarterly Journal of Agriculture.*]

We have now to commence the most important, but at the same time by far the most difficult branch of our subject; namely, the *Philosophy of Manure*, or the scientific principles upon which the cultivation of plants is founded. To accomplish this, with facility and perspicuity, it will be necessary to divide the subject into the following heads.

I. To give a clear view of the objects to be attained by the application of manure.

II. An account of the composition, and respective value, of some of the more important manures.

III. An account of the circumstances which should guide us in the choice of manure, and its application to various crops.

IV. The economy of manure, or the methods to be adopted in order to produce manure as quickly as possible, and likewise to apply it to the greatest advantage.

I. There is no point connected with agriculture, in reference to which more incomprehensible statements have been laid before the public, than those which have from time to time, and more especially lately, been published upon the subject, of manure; and it appears to me that these could never have been conceived, far less made public, had due attention been given to that branch of the subject, to which the present section is devoted, namely, the objects to be attained by the application of manure: these we shall now consider. We have already shewn that by far the most essential point to be attended to in the cultivation of plants, is to present to them a constant supply of organic matter, in a state capable of being rendered soluble in water; and we have moreover seen that this is accomplished, by adding to the soil, at certain intervals, various refuse matters, which are technically denominated *manure*, by which means all kinds of *dead* organic matter, are re-converted into *living* organized bodies; and consequently the objects of manuring may be described to be, the conversion of refuse matters into useful food; or in other words the duty and object of the farmer, is to *convert manure into crops*. This fact, however, appears to have been most determinedly overlooked by many late writers upon the subject, and in consequence there has been more nonsense and absurdity published in reference to this point, than one could have possibly imagined. Thus, for example we are most seriously told by a late writer upon fluid manure, that "there are many plants which by distillation yield a strong *spirit*, which is so powerful a manure, that, from some experiments he has *himself* performed, he confidently looks forwards to the time when the *manure* for an *acre of land* shall be contained in a *quart bottle*." This statement is really almost too absurd too refute, were it not that the opinion appears to be gaining ground in some parts of England. I trust therefore that my more enlightened readers will excuse me for occupying some space in proving the impossibility of such a thing being accomplished. It must be evident to all, who will take the trouble to think of the subject, that the weight of the crop must always bear some proportion to the weight of the organic matter in the soil; for, of what do vegetables consist?—Of *water*, *organic matter* and *earthy particles*. Now the first and last of these are supplied by the soil itself (considered as a mineral substance;) but the organized portions can be supplied to the plant only by organic matter, previously existing in the soil; for although plants do obtain some of their *carbon* from the air, still this is but an inconsiderable portion, and moreover much of the *carbonic acid* which yields that portion, has been supplied by the previous decomposition of organic matter. We may therefore infer, that should the above-mentioned author succeed in manuring an acre of land with the *contents of a quart bottle*, he will in time discover that the same article will be almost sufficient to contain his crop. But the believers of the above doctrine may say that the author has proved it by direct experiment, and consequently he must be either willingly deceiving the public, or must have some grounds for his statement. Now I have no doubt that the author is perfectly satisfied in his own mind that he is writing the truth, and I shall endeavor to shew how he has been misled. His *powerful spirit*, was of course applied to *soil*, (probably very rich garden mould) and the result was that it had a most powerful effect upon the vegetation of that soil, and in fact its influence was felt by "many succeeding crops:" but this by no means proves that his spirit is really a manure at all; it may act only as a *chemical* agent in producing the more rapid decomposition of the vegetable fibre of the soil, and thus rendering it soluble; and consequently his crops were produced by the *original organic matter* of the soil, and not by his *powerful spirit*. For had he continued its application from time to time, and taken care to prevent any subsequent addition of fresh organic matter, he would have undoubtedly found that his soil became exhausted. Let any one who doubts this statement, take soil free from all organic matter whatever; for example, let him mix artificially chemically pure sand, clay, and chalk in the same proportions as they exist in the best soils; let him sow his seed, and then apply this *powerful spirit*, and observe the results; let him weigh the products, and then be will, beyond doubt, see the truth of the fact, that the weight of the crop is proportional to the weight of organic matter in the soil. If the object of a farmer was merely to obtain good crops for a few years, and afterwards to allow the land to lie waste and useless, then, indeed, some powerful stimulus, such as the spirit in question, would be of great value; but, what farmer, I ask, would so wilfully injure his own interest, by thus exhausting his soil, for the sake of procuring one or two good crops?* Some persons, however, may remark, that it would be extremely difficult to prove the relation between the organic matter in the soil and the crop; for example, they might quote the case of turnips, where, in a good crop, two or more tons are produced, by a space of ground, upon which not more than one ton of farm-yard manure has been spread; and nevertheless there is sufficient nourishment left for several crops afterwards without any addition. I shall therefore shew the manner in which this relation is to be discovered, or at least point out some circumstances, which are liable to be overlooked, but which are of the utmost importance in any investigation of the kind. In the first place, the real weight of dry organic matter in a crop is extremely small in comparison to the weight of the crop itself; for instance 25 tons of globe turnips are calculated to contain only two tons of solid matter, of which a part of course is saline. Hence in that turnip there is not 8 per cent of organic matter. The grain crops of course contain a far greater quantity, but even in them more than one-fifth is composed of water and saline substances. Secondly, the quantity of organic matter in a soil is very liable to be underrated; as will be shewn by the following calculation. According to the analysis of Sir Humphrey Davy and others, good soil contains about 11 per cent at least of dry organic matter; now, taking nine inches as the depth of such a soil (which is by no means great,) it will be found by calculation that one imperial acre will contain no less than 91 tons of dry organic matter, and hence, were the whole capable of being converted into turnips without loss, each acre of good soil would (theoretically at least) be capable of producing upwards of 1200 tons of globe turnips before the land would be completely exhausted! A careful examination of these facts cannot fail to shew to all, the fallacy of judging of the power of a manure by its effects when mixed with *soil*. Of course I do not mean by this to dispute the value of experiments with different kinds of manure on various crops; but merely have endeavored to shew that, when authors attempt to talk about concentrating manure to such an extent, that the contents of a *quart bottle* will supply nourishment to the crop upon *an acre of land*, they should, in the first place, prove whether their substance is really a manure, or merely a chemical agent; and certainly ought not to give publicity to any opinions performed in a manner so replete with fallacies. The following fact alone should be sufficient to silence at once all such idle propositions. We have every reason to believe that "*creation* has long since ceased and *conversion* alone continues to take place," or in other words, "*new matter* is never now produced, but merely *matter already existing* is constantly *changing its form*." Much more might be said with reference to this point, but we have subjects of far greater importance to engage our attention, than the refuting of such visionary speculations. To recapitulate, therefore, the objects to be attained by the application of manure may be stated to be, the preservation of a certain degree of richness in the soil, in order that the seed sown may be furnished during all the stages of its growth, with a constant supply of organic matter, in such a form as to be capable of being absorbed; and moreover this organized matter being supplied by otherwise useless, and in fact injurious, substances, one of the national advantages of manuring land may be said to consist in the conversion of noxious matters into useful and wholesome food.

II. In giving a general account of the composition and respective value of the more important manures, we must remember that there are many collateral circumstances to be taken into consideration, which, although they may be of no importance theoretically, are nevertheless of such great practical consequence, that, without due attention to them, no scientific account of manure can be of any value to the farmer. *Manures* are generally divided into *organic* and *inorganic or mineral*. Professor Low, in his excellent work on practical agriculture, adds an intermediate division of *mixed manures*, which will aid greatly the consideration of this extensive class of substances. Properly speaking, the organic and mixed are the only true manures, the purely mineral ones acting either as *chemical* aids by promoting putrefaction; as *mechanical* agents by altering the texture of the soil; or probably also as stimulants, by acting directly upon the roots of the plants themselves.

I. *Organic manures.*—By adding organic matter to the soil, we are of course supplying plants with all that they require for their nourishment; nevertheless it is not sufficient that this organic matter should exist in the soil, it must be in such a state as to be capable of being absorbed by the roots of the plants; for which purpose we have already seen that its elements must be in that peculiar state of combination which has received the name of *humin*; or, to express it otherwise, in such a form as to be rendered soluble in water when exposed to the action of the spongioles. From this fact we may make several generalizations with reference to the respective value of different kinds of organic manure. Thus *scientifically* speaking, a manure may be said to be valuable in direct proportion to the quantity of pure organic matter it contains, its tendency to decomposition, and its facility of being rendered soluble by this, and other changes which take place in it: *practically*, however, a manure may be said to be valuable in direct proportion to the length of time during which its influence is felt by the crops on the land to which it is applied: as also to its portability, to the facility with which it can be incorporated with the soil, and, *last not least*, to its cheapness and the readiness with which it can be procured. Hence the most useful manure would be one which combined these several advantages, namely, one which was cheaply produced, easily carried, readily mingled with the soil, and when there, keeping up, by its gradual decomposition, a steady supply of *humin*, or other soluble organic matter. To discover such a manure, or, still better, to ascertain some method of imparting such properties to the manures in common use, would be one of the most valuable acquisitions to modern husbandry. That *chemistry* may in time be capable of doing this, there is little reason to doubt, all that seems, necessary, being, that some person properly qualified should earnestly devote himself to the task. In the following remarks upon the nature and composition of the different species of manure, particular attention will be paid to these qualifications. For the sake of perspicuity I shall subdivide that class of organic manures into the *purely vegetable*, the *purely animal*, and the *vegeto-animal*.

(1.) The *purely vegetable manures* are, green plants, rape-cake, malt-dust, the steepings of the flax and hemp, straw, woody fibre, tanners' spent bark, &c.

Green plants are constantly used as manure, and are very useful for that purpose; they are seldom collected expressly, but are made use of on the spot where they grow; as examples of this, we may mention the ploughing in of grass, and the ploughing and hoeing of weeds during fallow and green crops. This manure consists chiefly of saccharine and mucilaginous matters mixed with ligneous fibre; and it consequently will be observed that it requires no preparation whatever; that it contains organic matter already in a soluble state, namely the sugar and gum, and the ligneous fibre itself is so moist and so completely impregnated with vegetable juices, that fermentation rapidly commences, and consequently a supply of soluble matter will be kept up until the whole is consumed. Care must be taken, however, in ploughing in green crops for manure, not to make too deep a furrow, especially on strong lands; as in that case the quantity of soil which covers the vegetable matter is so thick that it diminishes the action of the air, &c. upon it; and it is a well ascertained fact, that fermentation is retarded, if not altogether prevented, by compression and the exclusion of air. The best period for ploughing in green crops (provided other circumstances permit of it,) is undoubtedly when the plants are in flower, as at this period they contain the greatest quantity of sugar and mucilaginous matter; and, moreover, in the instance of weeds, it prevents the possibility of their propagating their species by the scattering of their seed. The importance of allowing this species of manure to ferment in the ground, instead of in a heap, is, that (in addition to the great saving of labor) the slowness with which the decomposition takes place, is supposed to tend to produce much more soluble matter and less gas than when it proceeds above ground. The parings at hedge roots, scourings of ditches, pond-weeds, &c. may be used in this manner.

Rape-Cake has been used with great success as a manure: this, like the preceding, contains a large quantity of vegetable matter, already in a state capable of being dissolved in water, its composition being mucilage, a large quantity of vegetable albumen, a little oil, and woody fibre. It has the advantage over the former of being much drier, and hence containing far more manure in the same bulk of material; but, on the other hand, it is by no means so easily procured, and is much more costly. It is chiefly used in fallow, before wheat, and should be sown *fresh;* and before its application, should be kept as dry as possible, as moisture readily causes fermentation to commence, which, when once set in, will undoubtedly proceed with rapidity, unless the substance is carefully dried. And here we may make the general remark, that all substances which contain much fluid, and more especially such as are composed of mucilage, sugar, and other soluble matters, should be used when perfectly fresh.

Malt-Dust is mentioned by Sir Humphrey Davy as a good manure, on account of the quantity of sugar it contains. I have not, however, been enabled to meet with any particular account of its application; of course, if used, it should be allowed to ferment in the soil. The washings and other refuse of distilleries, I am informed, are much used in some parts of Ireland, as an application to grass lands, and their effects are stated to be very powerful. This, of course, will depend upon all the vegetable matter which it contains being soluble, and therefore very probably absorbed at once, without undergoing any decomposition whatever.

The next manure we shall mention, is one which can be applicable in a few cases only, on account of the local nature of its production; we refer to the *water in which the flax and hemp have been steeped*. It is well known that flax and hemp consist of the woody fibres of these plants, and that one of the first steps in their manufacture is the steeping of the plants in water, in order that the softer tissues may ferment, and the ligneous fibre be thus freed from the useless parts of the vegetable: of course, therefore, the water in which these plants have been steeped, becomes fully charged with *soluble* and putrescent vegetable matter, and consequently acts powerfully as a manure, and moreover requires no preparation whatever, as fermentation has already commenced. It is not necessary, however, to dwell much upon this subject, as its use must, of course, be confined to those districts where flax and hemp are cultivated.

Sea-weeds.—All sea-shore plants, especially those which grow below highwater mark, and which belong to the natural families of *Algæ* and *Fuci*, &c. contain more or less *mineral alkali (carbonate of soda,)* and have long been used as manure by the farmers in the neighborhood of the sea. They are, however, so succulent and mucilaginous, that their effects are by no means lasting; even when placed in heaps and allowed to ferment, they produce but very little heat; in fact, appear rather to dissolve away. They consist chiefly of water, mucilage, a small quantity of woody fibre, and saline matter; according to the analysis of Sir Humphrey Davy, nearly four-fifths was water, which contained no *ammonia*, and consequently the plants possess no *azote*. When applied to land, their effects are felt almost immediately, as the mucilage dissolves as soon as the outer covering of the plants is destroyed by fermentation; but from its soluble nature, its effects are but slight, and after the first year, are no longer perceptible. The alkali they contain must also act as a chemical solvent, which will hasten their consumption. It has been proposed, (see vol. iii. of this Journal, 1831-2,) to collect the sea-ware, and dry it by spreading it like hay, by which means, of course, nothing but water will be lost, and at the same time, the bulk will be reduced to one-fifth, in which state the author considers it to be a very valuable manure, and calculates that it can be procured and carted off at half the price of straw. This suggestion, I think, might probably be useful in some of the farming districts which are situated near the sea, but still not close enough to use the ware in its fresh state, as undoubtedly the manure is a good one as long as it lasts. The drying, also, will prevent the decomposition from taking place so rapidly as if applied when fresh.

Dry straw of wheat, barley, and other grain crops, and spoiled hay, are always useful manures. Sir Humphrey Davy, in speaking of these, adheres to the opinion which pervades the whole of his work upon Agricultural Chemistry, namely, that they should be applied fresh, and that if allowed to ferment, a large quantity of nutritious matter is lost. As this is a point more severely criticised than any other statement which his work contains, and as, moreover, it is one of extreme importance, I shall here enter fully into the subject, and endeavor to reconcile, if possible, the exceedingly discordant opinions which are entertained regarding it. To proceed, let us state the question. *Theorists* say all manures should be applied to the soil as fresh as possible, because, during the process of fermentation, if allowed to proceed above ground, much valuable matter is lost which would otherwise have been available to the crops. *Practical farmers*, on the contrary, maintain, that experience has proved to them, that, unless the manure is fermented to a certain degree before it is applied, it is not of half the value; in fact, in many nstances it greatly endangers the success of the crop. How, herefore, can these be reconciled? On careful examination we shall see, that here, as elsewhere, all the difficulties will vanish when *theory and practice* are brought jointly to bear upon the subject, in such a manner that the one shall correct the other; or, in other words, when the question at issue is compromised, so as to suit the purposes of the *farmer*, and at the same time, not contradict the statements of the *philosopher*. In the first place, we may take it for granted, that in all cases where *theory* is opposed to *successful practice*, the former will eventually be found to be at fault, for it is perfectly evident that the knowledge of the true theory must improve, instead of opposing those practices which time has shewn to be the most successful. Nevertheless, in the case before us, there is nothing *radically* wrong in the theory, but it has evidently been carried too far; in fact, it has been worked out, (if we may use the expression,) as a chemical problem, without due attention having been paid to the end in view; namely, the rendering of assistance to the farmer in his all-important operations. There is no doubt, for instance, that *carbonic acid* and *aqueous vapor*, are given out in abundance during fermentation, and also in the case of animal manures, *carbonate* and *hydrosulphate of ammonia*, all of which are in certain cases of great importance to plants. But it is not sufficient to prove a fact scientifically, and at once apply it to practice, for, unfortunately, such is the imperfect state of science at present, that there is scarcely a single instance where some modification is not required, when the two are brought to bear upon each other. For example in the case in question, it is not sufficient to discover that some of the value of the manure is lost during fermentation, and in consequence, to argue at once that manure should be applied fresh; we must prove in addition, that by so doing the farmer will not injure his interests in any other way; that, when so applied, it will serve all his purposes as well as when previously fermented. This, however, we shall not be able to do, for the following reasons. What the farmer wants when he applies manure to his land, is, 1, to enrich the land in such a manner that it shall be immediately fitted for cropping, and hence, a part of his manure must be *already* prepared for use, namely, rendered *soluble*. 2, The substance applied, must be in such a condition as to be easily incorporated with the soil, by the subsequent operation of tillage; and consequently must be in such a mechanical state, as not to interfere with these operations. Now, it has been proved scientifically, first, that when vegetable matter, and still more so, when a mixture of animal and vegetable matters, are exposed in a heap to the joint action of air and moisture, the temperature soon rises; chemical changes take place; part of the *oxygen, hydrogen* and *carbon*, go off in the form of *aqueous vapor*, and *carbonic acid;* and at the same time a part of the remainder is rendered soluble, either in the form of *humin* or some such combination; but, secondly, it has been proved that when these materials, instead of being heaped up, are spread out, and mixed with mineral matter, as when ploughed into the soil, the changes take place much more slowly; and lastly, it has been *conjectured*, but by no means proved, that when those changes take place in the soil, more soluble matter and less gas, is formed, and consequently that the effects upon vegetables are more powerful. Let us compare notes: The first object of the farmer is to have a supply of nourishment in a state fit for immediate use; but this can only be obtained by fermentation; and in the soil fermentation takes place very slowly; consequently, when fresh manure is applied, the seeds run a chance of having to wait for their food: and, moreover, it is a generally acknowledged fact, with reference to all chemical changes which masses of matter undergo, that these changes proceed much more rapidly after they are once fairly commenced, than in the first instance. Again fermenmentation softens and breaks down long straws, &c. which would otherwise make the husbandry extremely foul. This objection, in fact, presented itself to Sir Humphrey Davy, and to obviate it, he proposes the straw to be chopped before it is spread. The proper question for discussion, therefore, is not merely, as we have seen, whether fermentation is accompanied with loss; but whether the extra advantages attending the use of previously fermented dung will compensate for the loss sustained during its preparation. All practical farmers will doubtless answer in the affirmative; but even here we must be cautious how we generalize the principle. Practical men are at all times too fond of making general rules; for example, in the case before us, most farmers ferment their dung to a certain extent, *often much too far*, and then apply it to all purposes indiscriminately, whereas it is clear that the necessity of fermentation holds good only in those cases where an immediate supply of nutriment is required; and consequently, when a fallow is manured, or when the manure is ploughed in with the stubble in autumn, in preparation for the next year's green crop, the manure may be used in a much fresher state, especially on strong soils. This fact has been well illustrated in a paper, on "A new method of applying manure," by Mr. Baker of Nassau Cottage, near Leeds, which appeared in the 6th volume of this journal in 1836-7. The same plan is likewise mentioned in British Husbandry, in the Library of Useful Knowledge, under the article manure, where it recommends the fresh manure to be laid on the stubble during winter, and the long-straws raked off before the spring ploughing. It has been remarked, however, that the practice of ploughing-in raw manure in autumn, as preparative for the next year's crop, will not answer on light soils, as in this case a large quantity of the manure is lost; in fact I have been informed by an excellent authority upon such subjects, that nearly double the quantity in such soil, is required to produce the same effect when applied in this way, as when fermented above ground, and ploughed-in immediately before the spring sowing. This I presume must depend upon the open texture of such soil, by permitting rapid fermentation and allowing the gaseous parts to escape, and likewise the soluble matters to be washed deep into the soil as soon as they are produced. Thus we at once see how to compromise the question, and we consequently leave it in the following position, namely, that undoubtedly loss of manure is sustained by allowing fermentation to take place before it is applied to the land; but that this loss is more than compensated for, by the peculiar advantages of fermented dung in all cases where an immediate supply of nourishment is required. But on the other hand, that in those cases where the manure is to remain some months in the soil before the seed is sown, it should unquestionably be applied in a much fresher state, although even in this instance incipient fermentation may be useful, by rendering it capable of being kept up with greater facility, under the disadvantageous circumstances in which the manure is placed, when mixed with soil. I do not, however, by any means wish it to be supposed, that I consider the question as settled; far from it; the above statement is merely a representation of the case as it at present stands; but obviously a great deal has yet to be learned, more especially with regard to the *science* of the subject. We must return, however, to the consideration of the individual manures.

---

* And yet there are thousands of American farmers who are continually pursuing this *sinful* practice.—*Cond.*

Mere Woody Fibre.—At first sight one would be inclined to ask, when is mere woody fibre ever employed as a manure? But if we consider a little, we shall find two substances at least, which have been proposed as manures, to consist chiefly if not solely of this chemical compound—I refer to the refuse of the *tan-pit*, and *peat*. Both of these contain little or no substance besides mere woody fibre; for example, the operations of the tanner have removed all the soluble matter from the bark which he employs in his manufacture; and the long continued action of water has had the same effect upon peat. When we remember that the prime object of manuring, is to supply the plant with organic matter in such a state as to be capable of being dissolved in water, we must at once perceive that, theoretically, this manure is one of the worst possible kinds, if used in an unaltered condition, and practice has long ago proved the same fact; for Mr. Arthur Young, in his valuable "*Essay on Manure*," states, that "spent bark seems rather to injure than assist vegetation;" and it is well known that no plant can grow in soil where there is an accumulation of peaty matter. Mr. Young supposed that the injurious nature of tanners' spent bark depended upon the astringent matter that it contained; but Sir Humphrey Davy has shewn, that the processes to which the bark is subjected, free it entirely from soluble matter, and that the injurious action most probably depends upon the bark having a great attraction for fluids, and at the same time being impervious to the roots of vegetables. On this account, therefore, the bark would absorb the soluble parts of the manure, and thus deprive the plants of their food as soon as it was prepared for them. Even Sir Humphrey Davy, therefore, allows that *mere woody fibre* requires to be fermented before being used as manure; since, from the absence of all mucilaginous, saccharine, and other soluble matters, there is little or no tendency to decomposition, and consequently this must be brought about artificially; the best mode of doing which, is either to mix it with a quantity of hot lime, or to follow the plan proposed by Lord Meadowbank, of mixing it with farm-yard manure. The success of this latter method being dependent upon the fact, that if putrefaction commences at one point of a heap of organic matter, it will undoubtedly spread through the whole mass. In reference to the action of lime upon peat, &c. we shall say nothing at present, as this will be fully treated of when we consider the mixed manures.

(2.) *Animal manures.*—It is generally allowed that these require far less preparation, than those derived from the vegetable kingdom, since they have a much greater tendency to putrify, and hence of course do not require to be heaped together in order to produce this effect; besides their mechanical form is seldom such as to interfere materially with the various operations of tillage. They are comparatively seldom used alone, but nevertheless require consideration here, in order that the subsequent remarks upon the *vegeto-animal* composts may be more fully understood. The chief of them are—the various kinds of excrement, urine, hair, woollen rags, feathers, dead animals, fish, blubber and horn.*

Of the various kinds of *excrement*, *night-soil* is by far the most valuable. This substance has been long used by the Chinese, who mix it with one-third of its weight of marl, and dry it in cakes by exposure to the sun. These cakes are said to be void of all disagreeable smell. It is likewise prepared with quick-lime in France, and sold in the form of a dry powder, under the name of "*poudrette*," in which state it is sown with the seed in the same manner as rape-cake; the admixture of lime is merely to prevent the disagreeable odour which this substance otherwise possesses. There exists many prejudices against the use of this truly valuable manure, but it is needless to say that these are entirely without foundation.† The other species of excrement which have been used as manure, are those produced by the various birds and animals which are kept in a domesticated state. These have been found to be of very different degrees of power; the most valuable is supposed to be that of the *pigeon:* this, however, can only be used where great numbers of these birds are kept. It is stated to contain 23 per cent of soluble matter when recent, and hence will require no preparation before it is used. The next in order is the cleaning of *poultry-houses;* this is very similar to the last, and of course is produced in much greater quantity. A good method of using these manures, would probably be, to form them into compost with earth, dry leaves, &c. thus imitating the process which goes on in woods frequented by the wild pigeon, where the soil is found to be peculiarly rich and valuable. Of the excrementitious matters produced by the various domesticated animals, that of the *rabbit* is stated to be the most valuable; but of course it is liable to the same objections as those above mentioned, namely, the small quantity in which it is generally procured. Some farmers, however, have gone so far as to say, that is is profitable to keep rabbits for the sake of their manure; this, however, must be under very peculiar circumstances. Of the remaining manures of this order, that of the *sheep*, *horse*, and *swine*, are generally considered more powerful than that produced by *cows*. It is needless, however, to enter fully into the consideration of all these, as the whole of them act in pretty nearly the same manner, only with slight differences in their power. The composition of all this class of substances is the debris of the food taken by the animals, mixed up with bile and various other matters.

Urines.—These are all very powerful manures, but it is curious enough that, with one exception, they are all improved by putrefaction. The best way of using them undoubtedly is, to have the stables, &c. so constructed that all the fluid parts are carried into underground tanks, where they accumulate, and can either be raised by a pump and applied in the liquid form, or, which is probably the better plan when circumstances will permit of it, the tanks may be filled with porous earth, and the whole will then form an exceedingly rich compost: probably peat might be advantageously used for this purpose. In whatever way, however, this manure is applied, it is at all times most valuable. It abounds in *ammoniacal salts,* which have been supposed to be the cause of their injurious action when fresh, as it has been proved that solutions of these salts, unless extremely dilute, act injuriously upon plants; this, however, can hardly be the cause, as putrefaction increases instead of diminishes the quantity of ammonia. The one exception which I mentioned is the urine of the *sheep,* which is stated by all practical farmers to act as manure as soon as it is formed. Now, it is not easy to understand how this should differ from all other kinds of urine; but with the testimony of all farmers in its favor, it would certainly be worth while to have the point carefully examined into, before we endeavor to explain it.

Hair, Woollen Rags Feathers, &c. are all valuable manures, when they can be procured in sufficient quantity. All woollen rags are carefully collected by the inhabitants of the South of France, for the purpose of burying them at the foot of their olive-trees. Their composition appears to be chiefly gelatine and albumen. They decompose much more slowly than the generality of animal manures, and consequently, will probably be found particularly useful in those cases where a supply of *nitrogen* is required during the latter part of the growth of a crop, as for example in wheat. This subject I shall revert to when speaking of the application of manure to various crops. In the manufacturing districts the refuse of the different woollen factories will be extremely useful in this respect.

Dead Animals and Fish.—The former of these are very seldom used by the farmer, although it is evident that they would be extremely useful. Sir Humphrey Davy very properly proposes, that animals which die from disease or accident should (after having the skin removed) be covered with five or six times their bulk of soil mixed with lime, and allowed to decompose for some months, when the whole will be found to constitute a rich compost; the disagreeble smell of which may be prevented, by mixing lime with it when about to be turned. The refuse of slaughter-houses might be advantageously employed in this manner. Dead fish have been long known as a very powerful manure; they of course, however, are liable to the objection already stated, namely, the difficulty with which they are procured, except in certain situations. When employed, they must be mixed with soil and applied fresh, care being taken not to use too great a quantity, as they are very liable to produce rankness in the crop; their effects are felt for many years. The refuse of the fishmarkets, and that of fishing-villages, ought on this account to be carefully collected, and made into compost. *Guano*, a most valuable manure, which occurs in the South Sea Islands, in beds of from fifty to sixty feet thick, has been analyzed by Fourcroy and Vauquelin, and found to have a composition similar to the dung of sea-birds. This will account for its value, as in that case it will consist chiefly of the debris of fishes, mixed up with the ordinary constituents of the dung of birds.

Blubber and Horn are both very useful manures, when they can be procured; they both are composed almost entirely of animal substances, capable of being rendered soluble in water during putrefaction, and are at the same time in such a state that decomposition goes on slowly. We now come to the consideration of by far the most important of all species of manure, namely,

(3.) The *Vegeto-Animal* manures, or those which contain a mixture of animal and vegetable substances. These are chiefly the different varieties of stable-manure, &c. which are known under the name of "*farm-yard dung.*" This, from its abundant production, and many other causes, is beyond doubt by far the most valuable manure at present known. For example, it is valuable in a scientific point of view, because, being a mixture of animal and vegetable matter, it ferments easily, supplies a large quantity of soluble matter, and from its nature is capable of yielding nourishment to *all* kinds of vegetables. And practically, this manure recommends itself to the farmer,—1, Because it is necessarily produced in considerable quantities upon all farms where stock is kept; 2, Because, from this circumstance, it is evident that none of the crops consumed on the farm can be considered as lost; and 3, Because experience has long ago shewn that no manure is so generally useful.

It is needless to attempt to state the composition of a substance which must be of necessity so various; a few practical remarks will be, therefore, all that I shall introduce here. In the first place, it will be evident to all that the value of this manure will differ greatly according to the relative importance of its different ingredients; as, of course, since animal matters produce the greatest quantity of soluble nourishment, the greater the proportion of this class of substances the more useful will the compound prove. Again, it has been shewn that the period at which it is applied influences greatly its beneficial effects; for if allowed to rot away until it is reduced to the state of *soft, dark, unctuous mass,* not retaining any remains of vegetable structure, it can be easily shewn that more than one-half of its most valuable constituents have been lost. The remarks, however, which we have already made upon this subject of fermentation will, of course, apply here. It is stated in the Library of Useful Knowledge, in the article on British Husbandry, that the manure of fat beasts is much more valuable than that of lean cattle: this will very probably be the case, and, of course, depends upon the food with which the animals have been supplied. Thus, ten carts of dung from animals fed with oil-cake, were found equal to sixteen from those fed upon turnips. From this fact, therefore, it would appear necessary, that, in experimenting with this manure, we should pay attention to the food with which the animals have been supplied during its production. Much more might be said regarding the formation and management of dung-heaps; but this would involve us too much in pure practical farming.

Twelfth Annual Fair of the American Institute.

This anniversary celebration of industry and the arts will open to visiters at Niblo's Garden, in the city of New-York, the 7th of October next, at 10 o'clock, A. M. All articles brought to the garden are required to be entered by the clerk of the fair in a book. Those intended for competition for premium must be delivered either on Thursday, Friday, or Saturday, October the 3d, 4th and 5th, and reported to the clerk as for competition. If they are delivered at an early hour, and places assigned in the beginning of the fair, their location will not be changed, unless the general arrangements of the exhibition, in the opinion of the managers, render it desirable. They should be accompanied with a written description, as an effort will be made to publish a catalogue the first week of the fair. The accommodations of the garden have been greatly extended and improved since the last year. Two rooms, each 110 by 25 feet, have been added, adjoining and communicating with the great saloon, directly north.—All the departments of industry and of the arts, in the various sections of our country, are invited to make contributions of their choice specimens.

---

* *Bones* are often enumerated among animal manures, and their origin would certainly justify such an arrangement, but from the large proportion of earthy and saline matter they contain, they will be more conveniently treated of under the head of mixed manures.

† Animalized carbon appears to owe its fertilizing powers to this substance.

The deep interest taken at the last fair in the exhibition of cattle and farming stocks, and their importance to agriculture, the promotion of which is enjoined foremost in our charter, and the consideration that agriculture lies at the foundation of all production, has induced the Institute to resolve on another cattle exhibition and sale. Accommodations will be provided for pure blood cattle, horses, and extraordinary breeds of sheep, swine, &c. contiguous to the garden. Certificates of pedigree should be provided.

Much the greatest proportion of manual labor employed in production, is applied to agriculture. Here, then, is presented the widest field for the introduction of labor-saving machines. The farmer is much more secluded from the knowledge of these improvements than the manufacturer. The latter, availing himself of his advantageous situation, has, by the employment of machinery, dispensed with the greatest part of the most irksome toil and drudgery formerly required in his occupation.

The coming fair will present to the farmer the best opportunity of which he can possibly avail himself, for learning the properties of the newly invented, and the most valuable agricultural implements and machines, as they will be brought together for his examination. Those we intend particularly to benefit should not fail to be present.

We hope to see all the varieties and improvements of the plough. The Institute, by turning their attention to this indispensable instrument of husbandry, begin already to witness the benefits. One of its members has been induced to attempt the construction of a sub-plough, which promises great utility. Another has produced a steam plough, which has gone to the western prairies. It is ascertained that many of the ploughs in ordinary use require from 25 to 33 per cent more power to operate them, than those of the best improved construction. Even in Great Britain, with all their boasted culture, it is estimated that more than 1,000,000 of horses are employed in husbandry, and to a great extent the ploughs in use require 33 per cent more team than those of the best formation. The annual cost, only, at $25 each, amounts to $25,000,000. It will be evident, therefore, that in so great an agricultural country as ours, in many parts of which very defective ploughs are in use, the substitution of the most perfect construction, universally, would save millions in horses every year, and essentially contribute to our agricultural resources and national independence.

Inventors, manufacturers and owners of machinery are informed, that the Institute, to prevent disappointments, have purchased and located on the premises a steam boiler, of sufficient capacity to operate machines of the most massive construction.

Arrangements are making for a full display of American silk in all forms, from the cocoon to the finished fabric. Much good, we think, will result to the country from the preparations for the raising of silk. Our climate is peculiarly congenial to the insect that produces. The women, children and infirm persons scattered among our population, from whose labors little or nothing is realized, are competent to supply twenty millions of dollars value in silk per annum, instead of which we have imported in a single year more than that amount.—a sum double the value of the whole exported products of the United States, for the same period, from all our boasted fisheries, with all the exports from our forests, of skins and furs, lumber, masts, and all our manufactures of wood; our naval stores, tar, pitch, turpentine, pot and pearl ashes, &c. and also from our almost innumerable farms; all our exported beef, tallow, hides and cattle, butter, cheese, pork, bacon, horses, mules, sheep, &c. with our entire exports of wheat, corn, and flour, superadded. The whole catalogue of this formidable portion of a nation's hard earnings for foreign exportation, did not in 1836 equal twelve millions of dollars, while the imports of silks the same year, exceeded twenty millions of dollars; and by including silk and worsted goods, of which silk constituted an important part, they amounted to over twenty-three millions five hundred thousand dollars. This alarming statement, the report from the treasury department will fully verify. Is it not high time that silk should command our attention? The mulberry is essential to the worm that produces it. All its varieties should be collected at this fair, with detailed facts, showing their adaptation to soil and climate, and the quantity of sustenance they afford.

The general effect of the silk excitement, we think, cannot but be beneficial, as it will fill our country with mulberries, and every where afford food for silkworms; but it is vastly important in the commencement, that the kind best suited to our soil and our climate, and most bountiful in their healthy foliage, should be selected.

The early success of the silk culture will depend much on the perfection of machinery. The reel ought first to engage our attention. For ordinary household use, it should be cheap and simple in its construction, and its merits should be made public. For this purpose a gold medal will be awarded at the coming fair, for the reel which shall best answer the above description.

The public are looking with great interest to the investigations and experiments for deriving sugar from the beet.—We anticipate important improvements from the ingenuity and perseverance of a member of this institute, whose indefatigable exertions have been for several years applied in accomplishing a speedy and economical process for its extraction. Those who have witnessed some of the experiments have become convinced, that the sugar beet will, ere long, successfully compete with the sugar cane.

The manufacturers of cottons and woollens have at out latter fairs, come forward with renewed spirit. It is hoped that it will not only continue, but increase. The additional room which the new buildings afford, will enable the managers most advantageously to accommodate the exhibitors of cloths.

New machinery for the spinning of flax has been constructed. Specimens of the yarn should be forwarded, detailing the preparations necessary, the construction and operations of the machinery, together with their cost. Flax formerly ranked among our principal staples. For the last fifty years its culture has been on the decline. A perfect flax spinning machine would create a demand for flax, and soon cause it to be extensively cultivated.

Manufactures from various metals have, within a few years, increased and improved with great rapidity. Twenty-five years ago, domestic hardware was scarcely known in the New-York market. In 1836, it was ascertained that there had been actually sold within the city, in one year, more than seven millions of dollars value.

The specimens of iron castings brought to the last fair, conferred on the manufacturers the highest credit. The varied and perfect fabrics from malleable iron, (unknown until recently among us,) in an economical point of view, afford great promise.

In the manufactures of wood, particularly household furniture, useful and ornamental, we need not fear a comparison with the workmanship of any country. A few years since, most of our fashionable furniture was imported; our ingenious and skilful mechanics now successfully compete in foreign markets.

We now supply a great proportion of the glass which we consume, and have made profitable shipments abroad. The skill we possess has all been acquired within a few years.—The acquisition of the same skill in other countries, has required centuries.

Our hats and leather are not only sufficient for the home demand, with the exception of small quantities of the latter article for particular uses, but a large amount is also realized from their exportation. There are thousands of other articles worthy of particular notice, and many, perhaps more worthy than some we have named. To show the magnitude of our manufactures, we feel warranted in stating in general terms, that the exports to the south and to foreign countries of all the varieties of our manufactures, (produced in the northern and middle states,) though yet in their infancy, far exceed all our exports of agriculture from the same sections, and constitute our main reliance for meeting the demands continually accruing from abroad. Every thing in the past, promises well to our country for the future. We have only to rely on our own energies and resources.

An annual display, in this great emporium, of our best specimens, is signally calculated to awaken the genius of invention. Accordingly, every exhibition has brought forth some new improvement, till then not known. The multitude of competitors, the vast assemblage of inquisitive and scrutinizing visitors, whose attendance is anticipated by the exhibitors even before they commence making their specimens, the desire and the hope of winning the prizes, create an intensity of emulation among the competitors, that brings into action all their energies, and draws forth all their resources.

There were, at the least, 150,000 visiters entered the garden at the last fair, and about 1800 exhibitors presented themselves. Contributions were received from about 1500; they being all that were deemed worthy of exhibition. Among them were many entirely new; and others, not new, greatly improved. It will be readily seen, when each contributor brought on an average ten to fifteen articles, that even the names would occupy more than the space devoted to an ordinary circular.

The excitement created does not terminate with the fair. A determined purpose, an abiding resolution is made, to persevere, so that the close of one fair is only the signal of preparation for another. It is not within the scope of human invention to devise a plan, for carrying out the noble work of national industry and improvement, more general, pervading, and effectual. The belief that our country required a national institute for the general promotion of industry and the arts, induced tho proposition for a charter, and the city of New-York was selected as the appropriate location. The provisions of the charter were accordingly made to embrace the whole Union. Contributors and visitors, of all occupations and of every state, are therefore invited to join in the celebration.

A formal *resolution* of a large meeting, consisting of most of the distinguished members of the legislature, and others, held at the Capitol in Albany, was unanimously adopted, requesting 'the American Institute to call a convention of silk culturists, and those friendly to their interests during the ensuing fair. We, in conformity to that resolution and in behalf of the institute, hereby give notice that a suitable room will be provided for that purpose, on the evening next succeeding the evening on which the anniversary address is delivered. All who feel an interest in this subject are invited from this and other states. Silk culturists and silk manufacturers are particularly requested to bring forward all their best specimens, and to prepare themselves to give such useful information and explanations as will best promote this new branch of domestic industry. An examination of the best specimens that can be produced, and the interchange of ideas among experienced silk culturists, cannot fail to elicit important information, which, through the convention, may be spread before the public.

The essential prerequisite for the production of silk is already accomplished. Numerical calculation can scarcely keep pace with the multiplication of the mulberry. Should the enthusiasm for its propagation continue, America will soon afford more sustenance for the silkworm than the whole globe beside.

The encouragement given by the presence of such of our fellow-citizens as have been distinguished by high official stations, or for their wisdom or their learning, is most propitious to emulation and improvement. While they confer dignity on the anniversary, they operate as a powerful stimulus to greater and nobler efforts. Much profound reflection will be afforded them by this compressed view of a nation's unparalleled progress in the arts. The effect of minds and hands operating under the genial influences of constitutional liberty, will be impressively illustrated, imparting life and energy and confidence to industry, and awakening and quickening the latent powers of invention and genius.

At each of the eleven preceding fairs, the exhibition rooms have uniformly, at an early hour, been adorned with the delicate and tasteful productions of female ingenuity and skill, and the gaiety, fashion and beauty displayed through the day and evening by the fair visitors, have always been among the strongest attractions of the celebrations. They have shown that our Institute is their favorite institution. It has not been the gay tinsel and the glare of unsubstantial show, or unmeaning curiosity, that have moved them. It is a portion of that diffusive patriotism and pride of country which they have imbibed, and which every real American experiences, from the proud reflection that the triumphant displays are the exclusive products of their own native America.—They are respectfully solicited to honor the Twelfth Annual Fair by a continuance of their exhibitions, and with their accustomed cheering presence and approbation.

At the four last fairs, there were awarded as premiums, one hundred and twenty gold medals; six hundred silver medals; and about fifteen hundred diplomas—solely at the expense of the Institute. The managers do not intend to diminish the appropriations for rewarding merit, whilst the liberality of the public confers the power to bestow them. The determination of the merits of the respective articles entered for competition, will be submitted to competent and disinterested judges. If within the short space allowed for receiving, entering, arranging, and delivering articles, amidst the throngs of exhibitors and visitors, some errors should occur, or some omissions happen, which provoke the vociferations of disappointed expectation and passion, or which inconsiderate wantonness may distort and magnify—still, we trust, a considerate and liberal public will not expect the managers to be diverted from their arduous, engrossing and important duties, to indite contradictions and replies. Twelve years of faithful disinterested devotion to a cause which lies near the heart of every genuine American, have placed the American Institute in a position from which it cannot be expected to descend to repel attacks which have always proved harmless in effect, whatever may have been their design.

Agricultural Geology.

[*From Prof. Jackson's Third Geological Report.*]

Of all the arts, I know of none more likely to be improved by geological examinations, than that of Agriculture; since the composition of soils indicates their fertility, or capabilities of improvement, and the causes of barrenness. The science of geology demonstrates the origin, and distribution of the mineral matters, constituting the basis of all soils, to which they chiefly owe their peculiarities. I know that it is a favorite opinion with many agriculturists, that the mineral constituents of a soil have but little, if any influence on their fertility; and that they suppose the whole secret resides in the presence of certain vegetable or animal matters; but such a theory is at once exploded by an attentive examination of the natural soils, with their peculiar vegetation; for it will be seen that there are regular zones of vegetation, peculiar to each geological district, in which the same vegetable or animal matters are present, but which differ essentially in their mineral constitution. Thus how different is the soil derived from granitic rocks, from that which is formed by the disintegration and decomposition of limestones and slates. How peculiar is the vegetation which follows the great bands of trap rocks, and how remarkable is the growth on the ancient clay loams, of tertiary deposition. Whoever considers the attempts made to raise wheat upon soil totally destitute of lime, will at once appreciate the value of that mineral substance, and its importance in the production of grain. An imperfect or blighted product is sure to follow the planting of this grain upon soils destitute of lime, while it is well known that certain districts, where the soil contains this mineral, are always favored with luxuriant and heavy crops. This is one of the settled points in agriculture, and one which every farmer should duly appreciate, if he wishes to prosper in his art. Indian corn requires but little, if any lime, and hence we see excellent crops of that grain raised upon sandy plains, unsuited to wheat. Rye, likewise, will do pretty well without it, but it is always more full and heavy where it exists in the soil; and by attending to this circumstance, the value of the crop may be greatly improved.

The overlapping of soils, from diluvial causes, is also a point greatly illuminated by a knowledge of geology; and we are able, by means of a good geological map, to predict the nature of a soil in a given district, with as much certainty as we refer back certain rounded and transported stones to their native beds. It is also easy by the geological and topographical features of a country, to predict the nature of the alluvial or intervale soils, which have been washed down from the hills and mountains by brooks, rivers and rain; and such knowledge not only helps us to account for the phenomena in question, but also in the selection of suitable grounds for our various crops.

The situations in which are found substances capable of being used for the amelioration of soils, is also pointed out in a geological survey; and a scientific farmer soon learns to avail himself of the natural resources of the country. We also are able to indicate by the natural growth, the nature of the soil, and to point out to the farmer tracts of country which will form the best settling lands; and by the application of the science of chemistry, we indicate to him the peculiarities of the different kinds of soils, and the modes of renovating those which are deemed to be exhausted.

There are certain tracts, upon which gypsum acts favorably, while on others it does no good; and there are those where liming is required, and others where it is not. Some soils require the introduction of a quantity of vegetable matter, and we show the farmer the cheapest mode of introducing it; others are wanting in certain saline matters, required for peculiar vegetation, and the nature and quantity of such matter required, is indicated by a chemical analysis of the soil. Enormous quantities of valuable materials in manures, are lost by a want of chemical art in preserving them, and still more is wasted by improper application. The causes which effect these results, are well known to chemists and geologists, and by special examinations, the knowledge is applied to particular cases with skill, and with certainty in the result; whereas vast amounts of both time and money are lavished in idle experiments, by those who are unacquainted with the laws of nature.

It is to correct these errors in agriculture, that science, "the handmaid of the arts," comes to our aid, and by learning and following her laws, we soon come to a more perfect knowledge of the subject, and with the lever which she puts in our hands, overthrow all obstacles. Why is it that the noble art of agriculture, holds so low a rank in the opinion of men, if it be not that reason has left the field, and given place to empyricism? If it is ever to be restored to its pristine rank, and a new Eden is to bloom, with its fruitful fields, it must be by bringing the GOD-LIKE attribute of man to the task of renovation. I have always been startled with the gratuitous assumption, that knowledge and reason were not to be the rules of agricultural labor. That any one knows enough to be a farmer, and that the *concentrated experience of the world was not to be put in competition with the narrow circle of individual experience!* Is it indeed so with any other science or art? Or should we not conceive it to be arrant folly for any one to pretend to learn any other business, without availing himself of the knowledge of others? I know that intelligent men make no such gratuitous assumptions; but still there may be many, who are not aware of the application of certain sciences which I mention, to the improvement of this most important of arts, or they may have but a partial glimpse into the arcana of science. Others may have formed an opinion, that since science is confessedly imperfect, that it cannot meet the exigencies of the case, but that innovations upon ancient customs are fraught with danger. To such we may reply, that enough is already known to render the art great service, and that knowledge is marching on with such rapid strides, that we should hasten in our movements, lest all hope of overtaking her should be lost.

I knew a gentleman once, who stated that he was waiting for the science of chemistry to come to a stop, before he engaged in the study. It was then comparatively easy to acquire the mass of information requisite for the comprehension of that science. But now look back to the accumulated knowledge on this subject, which has loaded our shelves with ponderous volumes. Is there now any better opportunity of overcoming the difficulty? So it will shortly be with scientific agriculture. But comparatively few are the records now—but with the new impulse it has received, in a few years it will cause "meek-eyed patience to fold her arms in despair," when contemplating the mass of materials that will be collected for our instruction. "Little by little the bird makes its nest;" and so must we gradually collect the materials of knowledge. Let the young farmer, therefore, be on the alert, and not let the rest of the world get the start of him in his art. Agricultural colleges are required throughout our country, and the time is not far distant when we shall see them in full operation. Analytical chemistry and geology will be among the essential principles of a farmer's education. Botanical knowledge will teach the peculiarities of plants, and their adaptation to peculiar soils; and chemistry will teach us so to modify our soils as to produce such results as are required. In the mean time, a few professional men must take the burthen upon their shoulders, and aid the farmer in his first steps in science. Mutual aid and good fellowship, will make the burthen light, and both parties will profit by their association. The farmer, attached to one spot, has great advantages in obtaining facts, which more fully illustrate the knowledge of that particular district. The facts so obtained, are to be collated and duly explained, so as to become capable of forming general rules or principles, for the guidance of others. Soils remarkable for peculiar vegetation, luxuriant or barren, form subjects of particular interest, capable of explanation by chemical analysis.—The present state and future condition of a soil, can in a certain degree be ascertained by a knowledge of their geological origin, and the nature of the chemical reactions which will take place in it. Advantage may sometimes be taken of defects in soils, to render them the most powerfully beneficial. Thus, in the town of Saco, there is an intervale plain, belonging to Mr. I. Jordan, having several remarkable substances in it, which nothing but a knowledge of geology and chemistry could explain or improve. There is a kind of clay marl, filled with minute and almost invisible particles of pyrites or bi-sulphuret of iron, composed of 54 parts sulphur and 46 of iron. The marl also contains three per cent of carbonate of lime, and the remainder is clay.—When this substance is first dug up, it is without any saline taste, and nearly inert; but upon exposure to the air, it crumbles, and after a while, becomes charged with copperas or sulphate of iron, which is formed by the oxidation of the sulphur and the iron, by atmospheric action. While in its first stages, it acts as a powerful fertilizer, for the sulphuric acid is taken from the iron and combines with the lime, forming gypsum or sulphate of lime, while the oxide of iron is deposited. After a while, the copperas or sulphate of iron, constantly forming, gains the ascendency, and then has powerful corrosive properties, nine or ten per cent of sulphuric acid being produced; and having no lime with which to combine, it attacks the roots of the plants and kills them. (See chemical analysis of this copperas marl.) Thus, as Mr. Jordan happily expressed himself, "it first makes the corn grow, and then eats off its roots and kills it." Certain other plants of the *gramineæ*, are capable of withstanding this substance, if not in great excess; and hence herd's grass, rye and wheat, are not so likely to be destroyed by it, since they are armed with a coat of mail composed of silex, which envelops their whole surface; but all herbaceous or tender plants are cut off by it.

Here, then, we have a defect to remedy, and to turn to our account, and it is an extremely simple case, for we have only to add a sufficiency of lime to the copperas marl to render it one of the most valuable and powerful fertilizers. Thus a compost heap affords us an accessible remedy, and the enemy is soon tamed and made subservient to our will. The origin of this pyritiferous clay is at once explained by geology, which teaches us that it is composed of the fine particles of pyritiferous slate rocks, that have been deposited by water. So also the occurrence of nodules of shot and nut iron ore in it, and the mineral waters which flow from the meadows charged with sulphate of lime, explain themselves by the reaction of carbonate of lime upon sulphate of iron, an exchange of elements taking place in accordance with the well known laws of chemical affinity.

Peat also occurs abundantly in the same meadow, and by a little chemical skill may be converted into an excellent manure, by means of a mixture of lime and a little barn-yard manure or any animal matter. Thus three or four cords of the peat mixed with one cord of animal manure, and treated with a cask or two of slaked lime, will make a compost superior in value to five cords of the best stable manure alone. They ought to be placed in alternating layers, thus:

PEAT,
LIME,
ANIMAL MANURE,
PEAT,
&c.

The whole forming a regular compost heap. The chemical reactions which follow are chiefly thus:—

The lime extricates a large quantity of gaseous ammonia from the animal matter, which is absorbed by and enters into combination with the peat, and is thus retained ready for use in the state of ulmate or geate of ammonia—(a most powerful manure)—and the lime becomes completely carbonated or air slaked by the carbonic acid given out during fermentation, and in this state is a proper and permanent ameliorator of the soil. The peat is converted into a powder and soluble pulp, and becomes more suitable for the nutriment of plants. While if lime and animal matter was used in excess we shall have also a considerable quantity of carbonate of ammonia, in the peat, a well known and powerful saline manure.

In case the soil is sandy, the clay marl, neutralized with lime, is the most proper amendment for it, and such is generally the condition of the fields in Saco, so that by a proper use of this marl, the happiest effects may be realized by the farmers in that town.

I could quote other instances of the kind, but the above fully illustrates my meaning, and will show how favorable an influence scientific knowledge would exert in agriculture, were it more generally appreciated.

The principles which I have laid down, have been adopted by several distinguished farmers of Massachusetts, and their experience most fully corroborates the truth of the theory inculcated.

I need but appeal to the experience of one of our most intelligent farmers in Massachusetts, Elias Phinney, Esq. of Lexington, to demonstrate the correctness of the rules we have laid down, with regard to the use of peat for compost manure, or to the beautiful farm of Benjamin Bussey, Esq. of Jamaica Plain, Roxbury, where similar results have been obtained.

"*Lexington, January* 30, 1839.

"DR. CHARLES T. JACKSON—Dear Sir—I herewith send you a sample of my peat. I am very desirous of availing myself of the benefit to be derived from a chemical analysis of the same, which you kindly offered to make. A more intimate knowledge of the nature and properties of peat, which can be obtained only by a scientific examination of its constituent parts, would enable farmers more justly to appreciate this valuable species of land. It is from a want of this knowledge, that our extensive tracts of low meadow and swamp lands have hitherto been esteemed of little or no value.—Allow me to say, sir, that I know of no way, in which you could render a more essential service to the public, more especially to farmers, than by enabling them to convert their unproductive and unsightly bogs and morasses into luxuriant fields and sources of wealth. I consider my peat grounds by far the most valuable part of my farm; more valuable than my wood lots for fuel, and more than double the value of an equal number of acres of my uplands, for the purpose cultivation.

"In addition to these, they furnish an inexhaustible supply of the most essential ingredient for the manure heap. A statement of the uses, to which I have appropriated peat lands, and my management of them, though very imperfect, may serve to give you a partial conception of their value and uses, and at the same time enable you to see how important it is that the farming community should have more information on this subject.

"In the first place they are valuable for fuel. I have for twenty years past resorted to my peat meadows for fuel.—These, with the prunings of my fruit trees, and the brush from my uncleared lands, have given me my whole supply. The prunings and brush are bound in bundles, and housed, and with the help of a small bundle of these faggots and peat, a quick and durable fire is made. It gives a summer-like atmosphere, and lights a room better than a wood fire. The smoke from peat has no irritating effect upon the eyes, and does not in the slightest degree obstruct respiration, like the smoke of wood; and it has none of that drying, unpleasant effect of a coal fire. The ashes of peat are, to be sure, more abundant, but not more troublesome, and are less injurious to the furniture of a room, than the ashes of coal.

"The best peat is found in meadows, which have for many years been destitute of trees and brush, and well drained, and where the surface has become so dry, and the accumulation of decayed vegetable matter so great, that but little grass or herbage of any description is seen upon the surface. If the meadows are suffered to remain in a wet and miry condition, the wild grasses and coarse herbage will continue to grow, and the peat be of a light and chaffy texture, fixed with undecayed fibrous roots. By draining they become hard, and the peat becomes compact and solid, and the cutting out and carrying off greatly facilitated. A rod square, cut two spittings deep, each spitting of the length of eighteen inches, will give three cords when dried. It may be cut from May to September. If the weather in autumn be very dry, the best time for cutting will be from the middle of August to the middle of September. If cut the latter part of summer, or early in autumn, it dries more gradually, and is not so liable to crack and crumble, as when cut early in summer. The pieces are taken out with an instrument made for the purpose, from two to three inches square; and if of good quality, will shrink about one-half in drying. It is considered a day's work for a man, a boy and a horse, to cut out and spread a rod square. The man cuts it out and lays it upon a light kind of drag, made for the purpose, and it is drawn off by the horse, and spread by the boy as thick as the pieces can lay singly. After becoming dry enough to handle without breaking, it is made into piles, cob-house fashion, of from twelve to twenty pieces in a pile. It will then require about four weeks of dry weather to render it fit to be housed for use. The top, or turf, is thrown back into the pits, from which the peat is taken; and if well levelled, and the ground drained, it will, after the first year, give a large crop of foul meadow, or other lowland grass. Peat, taken from land which has been many years drained, when dried, is nearly as heavy as oak wood, and bears about the same price in the market.

"The value of peat and swamp lands for tillage, is now pretty well known, and acknowledged. Some years since, I occasionally sold to my neighbors a few rods of my peat land, yearly, to be cut out for fuel, at three dollars per rod, being at the rate of four hundred and eighty dollars per acre; but finding this sum to be less than its value for cultivation, especially when laid to grass, I have declined making further sales at that price. I have raised upon my reclaimed meadows, seventy-five bushels of corn, five hundred bushels of potatoes, or from four to five tons of the best hay, at a first and second cutting, to the acre, at a less expense of labor and manure, than would be required to produce half this crop upon uplands. To render these lands productive, they should be thoroughly drained, by digging a ditch around the margin of the meadow, so as to cut off the springs, and receive the water, that is continually flowing in from the surrounding uplands. If the meadow be wide, a ditch through the centre may be necessary, but this will be of no use, without the border ditches. This being thoroughly done, and the surplus water all drawn off, the next step is to exterminate the wild grasses, and herbage of every kind, that grow upon the surface. To effect this, the method heretofore generally, and now by some pursued, is to cover with gravel or sand, top dress with manure, sow the grass seed, and then rake or bush it over. This, for the first year or two, will give a good crop of hay; but after this, I have invariably found that the more coarse and hardy kinds of wild grass would work their way through the sand or gravel, and entirely supplant the cultivated grasses—when the whole must have another covering, or be abandoned as worthless. If to be planted with corn, or any of the root crops, my course has been to turn over the turf or sward with a plough having a wrought iron share or coulter, ground to a sharp edge, in the driest season, say in the month of September, roll down as hard as possible, carry on in the winter a sufficient top dressing of compost, twenty cart loads to the acre, and in the spring plant with corn, or roots, without disturbing the sod. When the corn or roots are taken off, the surface is made smooth with the cultivator, or hoe and harrow, and late in November, or just before the heavy frosts set in, sow with herd's grass and red top seed, half a bushel of the former and one bushel of the latter to the acre. The field is then rolled, which completes the process. If the plough does not turn the sods smooth, it will be necessary to follow it with a bog hoe, to level the uneven places. By keeping the sod undisturbed in the cultivation, a more firm and compact surface is formed, upon which oxen or horses may work generally, without danger of miring. If the land is intended for grass, without the intervention of a hoed crop, the turf is turned over with the plough, as before stated, in August or September, or as early as the surface becomes dry enough to admit the oxen or horses upon it; then follow with the bog-hoe and turn over such parts as the plough has left unturned, make the whole smooth with the hoe, and late in November, spread on a top dressing of compost, not less than twenty cart loads, made half of loam, and half of stable manure, to the acre; then sow the grass seed, and bush, and roll down. If the ground be miry, so as to render the use of the plough impracticable, the bog hoe must be resorted to, and the whole turned over by hand, and top dressed, and seeded to grass, as above stated. The cost of turning over with the hoe, will be twenty dollars per acre, at the usual price of labor. This mode of culture completely subdues the natural wild grasses, and gives a compact and rich surface of vegetable mould, which will give an abundant crop of the best English hay for four or five years, without the aid of more manure. If the sod is disturbed and attempted to be pulverized in the course of the cultivation, the surface, when laid to grass, will be loose and spongy—an extra top dressing of loam and manure will be required, and after all, the surface will not become so compact, nor the produce by any means so great. Should meadows be found too soft and miry to admit of their being ploughed in the summer, or autumn, and the expense of turning with the hoe should be thought to be too great, I would advise ploughing in the spring, when the frost is out to the depth of three or four inches, carting on the manure, and then sowing or planting at a convenient and proper season. The art of reclaiming these low meadows, consists in taking off all the surplus water by judicious draining, and in thoroughly exterminating the natural herbage and grasses. This being effected, we have our rich bottoms, equally as productive as the deep alluvials of the west, and obtained at a cost and sacrifice infinitely less.

"The third particular in which peat lands may be considered valuable to the farmer, consists in furnishing him with a very important ingredient for his compost. Peat is made up principally of decomposed vegetable substances, with a portion of the lighter particles of vegetable mould, washed in from the surrounding highlands. But when taken fresh from the pit, it contains certain antisceptic properties, injurious to vegetation, which must be absorbed, or neutralized, by a combination with other substances, in order to render it food for plants. This may in some measure be effected by exposure to the action of the air and frost. Where the surrounding uplands are composed of gravel or sand, the peat or swamp mud may be called silicious, and is less valuable for manure, especially if the adjacent uplands rise abruptly—when composed principally of clay, the peat is aluminous—this is frequently found resting on beds of marl, and is considered much richer, and more valuable for the compost heap.

"I have annually, for some years past, used on my farm some hundreds of loads of peat mud, which is either thrown into my hog-stye, or mixed with fresh stable dung, or with lime. When mixed with green stable manure, the proportions are two parts of peat mud to one of dung; and I am confident, from repeated experiments, that a load of this compost, well mixed and fermented, will give as great a produce, and a more permanent improvement to the soil, than the same quantity of stable manure. In this opinion, I am not alone. Other accurate and intelligent cultivators, have made similar experiments with similar results.

"The vegetable substances of which peat is composed, having been decomposed in stagnant waters, they have not passed through a putrefactive fermentation, and are therefore supposed to contain much of their natural oils, gums and acids. Peats, in this region, are also supposed to contain portions of sulphate of iron, or copperas, oxide of iron, &c. This opinion is formed from noticing the difference between the effect produced by using the peat mud on grounds, when first taken out of the meadow, and that which is produced after fermentation, with stable manure, or by mixing it with lime. The ashes of peat have little or no perceptible effects, when used alone, but by mixing them with lime, they become a valuable manure.

"That our peat may possess other and different properties, which are in a greater or less degree injurious to plants, is highly probable. These can be detected and remedied only by the aid of science. It is to the agricultural chemist, that the practical farmer must look for a development of his resources, to remove the obstacles which impede his progress, and to impart that information which will give confidence to action, and a successful issue to labor.

"With an earnest desire that you may persevere in your useful labors, I am, dear sir, with the highest respect, your obedient servant, E. PHINNEY."

(To be continued.)

Annual Address.

Before the Kentucky State Agricultural Society—delivered at the Capitol in Frankfort, January 14, 1839, *on the dignity of the profession of agriculture, and the propriety of legislation for its improvement.*

BY COL. C. S. TODD, OF SHELBY.

Gentlemen of the State Agricultural Society—In compliance with the invitation of our worthy President, I appear before you this evening, in behalf of the great interest which sustains every other interest in the community; and relying upon your indulgent feelings towards a cultivator of the soil, entreat you to forget, in the magnitude of the subject, any deficiencies of the advocate.

In entering upon the duty assigned to me, I feel a consciousness of the difficulties which beset my path, arising as well from my own inadequacy to the task, as from the nature of the subject, which is generally considered not to be susceptible of those illustrations and attractions, rendered so interesting in this age of improvement, by the exertions of cultivated intellect applied to the departments of law, physic, moral and political economy. All that I can hope then to effect, will be to lead abler minds to reap laurels in a field in which, as a pioneer, I shall be content if the public mind be directed to the subject.

As the advancement of the cause of agriculture is the exclusive object contemplated in the formation of this society and of the annual meeting on this day, I propose upon this occasion, to examine this subject in two of its most interesting aspects—first, to present to my brother farmers some of the considerations which should lead them to form and act upon a more exalted estimate of the dignity of their profession; and then, to offer some suggestions, which, it is hoped, may have a tendency to stimulate the legislative councils to that encouragement of the cultivation of the soil, which an enlightened forecast deems to be so intimately connected with the public welfare.

In the first place, as to the dignity which belongs to the pursuits of agriculture. The illustrious Franklin, whose eulogy was conveyed in such felicitous language by the eloquent Mirabeau—"*Eripuit cœlo fulmen sceptrumque tyrannis;*" the sage, whose fame shed lustre on the age in which he lived, and who sustained towards his country the envied attitude of mechanic, patriot, stateman and philosopher, has pronounced "agriculture to be the most honorable of all employments, being the most independent. The farmer," says he, "has no need of popular favor, nor of the favor of the great; the success of his crops depending only on the blessing of God upon his honest industry." The occupation of the farmer is not only honorable, as being the first pursuit of man, and as having engaged the attention of the most virtuous and illustrious men in every age, but it is the most honorable for the precise reason stated by Franklin—it is the most independent. The other pursuits of men, in all their diversified forms, depend in a greater or less degree upon the success of those who exert their energies in other avocations—the merchant depends upon the farmer and manufacturer—the mechanic upon the farmer and merchant, and the professional man upon all of them; but Franklin, as well as the experience of ages proclaims, that the farmer is independent of all save "the blessings of God upon his honest industry."

Washington, the father of his country, has declared that "he knew of no pursuit in which more real and important services can be rendered to any country than by improving its agriculture." Socrates, one of the most eminent of the ancient philosophers, says, "agriculture seems to possess an incontestible right to the title of parent and nurse of all other professions;" and the celebrated Vattel, of modern times, whose treatise on the Law of Nations is regarded as the standard of international duty amongst the most enlightened states of the present day, says, "of all the arts, tillage or agriculture is doubtless the most useful and necessary; it is the nursing father of a state; the cultivation of the earth causes it to produce an infinite increase; it forms the surest resource and the most solid fund of rich commerce for the people who enjoy a happy climate."

Agriculture was the first avocation of man, Adam being directed to "dress and keep" the garden of Eden. This was his duty in the days of primeval innocence; and after the fall, he was required to earn his bread by the "sweat of his brow." The first valuable improvements in husbandry were made by Noah, who, though a preacher of righteousness, was called a man of the ground, because of his advancement in agriculture and his invention for subduing and fertilizing the soil. The divine command to the Jews, "break up your fallow ground and sow not among thorns," is applicable to all the nations who live by the cultivation of the soil; and I indulge the hope that there is not a christian farmer in our land, who, while he recognizes the spiritual beauty of the passage which has immediate reference to the cultivation of the heart, does not feel its literal force in calling upon him to adopt all practicable means of improving the soil committed to his care. And here it may not be impertinent to remark, that if the mass of my brother farmers would "indeed break up their fallow ground and sow not among thorns," as well in relation to their husbandry as to the cultivation of their minds, we should not be placed, as a profession, in the rear of other less worthy pursuits.

The descendants of Abraham in Palestine, the Chaldeans, the Egyptians, the ancient Persians, the Phœnicians, the Athenians, and the Romans, including those in the highest offices in each of those nations, manifested the highest regard to the pursuits of agriculture. Hesiod and Xenophon of the Greeks, and Cato, Varro, Virgil, Pliny and Columella, of the Romans, published treatises on the subject—and the greatest improvement was made in agriculture during those periods of the ancient nations, when their institutions approached more nearly to the republican character. Xenophon, one of their historians, remarked that "agriculture is the nursing mother of the arts, for, where it succeeds prosperously, there the arts thrive; but where the earth necessarily lies uncultivated, there the arts are extinct." In the best days of the Roman republic, he was entitled to the highest praise who "best cultivated his spot of ground," and such should be now the tone of public sentiment. Montesquieu has observed that "countries are not cultivated in proportion to their fertility, but to their liberty;" and the conductor of the New-York "Cultivator," who unites in himself, more eminently than any other citizen of the republic, the rare qualities of scientific knowledge and practical experience with a polished pen, lays it down as almost a maxim, that "the mental and moral condition of an agricultural district is in the ratio of its improvement in husbandry."

There is a moral beauty in the sentiment of Franklin, which maintains that the farmer is independent of all, save "the blessing of God upon his honest industry." Those who plough the land, as well as those who plough the sea, are under peculiar obligations to recognize a special and superintending Providence. The farmer has the promise of seed time and harvest; the seasons, the rain, the warmth of the sun, the growth of the soil, and all the operations of nature, admonish him, of the exertions of an Omnipotent energy. In the country he seems to stand in the midst of the grand theatre of God's power, and seeing that the succession of heat and moisture constitutes the sources of production, he is led to feel in the action of the sun and the descent of dew and rain, his obligations to reverence that unsearchable sovereign without whose permission not a "sparrow falls to the ground," nor a blade of grass springs up. The sailor, too, looks through the elements to the great first cause, and the man at sea must be insensible to all the high and holy motives of gratitude, who does not feel his own impotency, not less than a reverential awe of that Supreme Power whom the winds and waves obey.

Ancient and modern poets have dignified the cultivation of the soil by the majesty and melody of their immortal songs. Virgil, the great Roman, has left an imperishable monument of his devotion to the cause of agriculture; and strange as it may seem to some of our modern farmers, some of whom affect not to need any instruction in the science upon whose successful application they depend for support, Virgil gives in his Georgics much of what constitutes the present mode of ameliorating the soil. An interesting extract which may be found in book I, line 79-80, speaks of the Roman practice of saturating the parched soil with rich animal manure, of scattering sordid ashes upon the exhausted lands, and of giving rest to their fields by a rotation of crops; to which if we add the later process of renovating through the introduction of the grasses and the application of marl, we shall have the present improved mode of farming as practised in our own country. Milton, the Homer of modern times, (both of them blind to natural, though touchingly alive to moral beauty) occupied his master mind in delineating the paradise which Adam was directed to "dress and keep;" and Thompson has presented aftertimes with a surpassingly beautiful scene in his autumn, where he introduces among the gleaners of the harvest,

> "The lovely young Lavinia, who once had friends,
> And fortune smiled deceitful on her birth."

A sentiment as descriptive of the benevolence which belonged to the period of harvest as it is illustrative of the career of thousands upon whom the sunshine of prosperity in early life has only dawned to render the gloom of adversity more conspicuous in their declining days.

Ancient and modern patriots have been devoted to the cultivation of the soil. Cincinnatus, Dentatus, and Regulus, La Fayette, Washington, and our own Shelby, are illustrious examples of this interesting fact. They repaired from the plough to the defence of their country, and from the defence of their country returned to the plough; and although they were renowned warriors, we must suppose there was a redeeming spirit in the nature of their avocations as cultivators of the soil, which caused their love of country to be superior to all selfish considerations. Considered in this aspect, their fame will live undimmed in the records of time, whilst the memory of the Cæsars and Alexanders, the Bonapartes and Iturbides will rot, like the "memory of the wicked." Of Cæsar, nothing is left but his accomplished commentaries and his unhallowed ambition. Of Alexander, who shed tears because he had no more worlds to conquer, no monument remains but the city of Alexandria in Egypt, once the pride of the world in its unrivalled library, and when it commanded the commerce of the Mediterranean sea and the Arabian gulf, but now only a scene of magnificent ruin, since the discovery in the 13th century, of a new route to the East Indies by the Cape of Good Hope. In a few years posterity will only speak with approbation of Bonaparte as having left a valuable code of laws for France, and as having established agricultural societies and professorships, and the National garden; whilst the frequent and inexplicable revolutions in former Spanish America will only serve to proclaim the succession of military tyrants, countenanced alone in countries where the system of religion prescribes the rights of conscience as well as the lights of knowledge.

The most distinguished individuals in our country, including nearly all of our Presidents, have delighted in the pursuits of agriculture. Washington, whose career presents the brightest example of true glory recorded in ancient or modern history, was impatient to retreat from the toils of war and the cares of state, to betake himself to the pure and unalloyed joys of rural life. Jefferson, whose fame is identified with the independence of his country, rejoiced in the opportunity of mingling the avocations of the farm with the sweets of polite literature. Madison, whose monument is found in the matchless constitution he contributed to form and which he administered in peace and in war, was always anxious to retire to the mellow pursuits of agriculture, as the most congenial in their influence upon the profound and classic efforts of his unrivalled pen. Monroe, who fought in both wars for the maintenance of his country's independence, and whose career is signalized by association with the purchase of Louisiana and Florida; the heroic Jackson, whose fame will live as long as the waters of the father of rivers roll on to the ocean; our own eloquent Clay, the great unsurpassed of modern statesmen, and our own veteran Harrison, whose patriotic policy founded and whose skilful valor defended the vast North-West—these all have manifested a deep solicitude for the interest of the great cause which we have this day convened to promote.

To descend to our own history as the first republic in the wilderness of the great west, we have many noble examples of our most distinguished citizens devoting themselves to the pursuits of agriculture. At an early period, Shelby, Nicholas and Breckenridge were conspicuous in their efforts to advance this great object. The first, renowned in the war of the revolution, and in the early as well as the after history of the state; the two latter, his equals in vigorous intellect and patriotic devotion, whilst they were scarcely excelled in the whole Union in their enlightened advocacy of the principles of constitutional law. In our own day we find the whole community in its civil, political and religious character, coming up to mingle its tears with ours over the graves of the lamented Garrard and Green, who, after signalizing their valor in the North-West, considered it their proudest claim to distinction in devoting their strong minds and patriotic hearts to the great cause of agriculture. And passing from our own country and our own age, we may refer to the fact which is exhibited in bold relief in the history of every nation claiming to be civilized, that men of every profession, in all ages, have contemplated at some period of their career, to retire to the repose to be found only in the pleasures of rural life. The statesman, the civilian, the philosopher, the physician, the merchant, the handicraft tradesman, the county court pettifogger, the village constable and the heartless usurer, all fix in their minds some future day in which they hope to realize what their imaginations have depicted of the joys of retirement in the country.

As a further illustration of the value which highly gifted men have attached to the pursuits of agriculture, I venture to introduce an extract from the essays of Dr. Johnson, who stands at the head of British literature. It is allowed that "vocations and employments of vast dignity are of the most apparent use; that the meanest artisan or manufacturer contributes more to the accommodation of life, than the profound scholar and argumentative theorist; and that the public would suffer less present inconvenience from the banishment of philosophers than from the extinction of any common trade."

"Some have been so forcibly struck with this observation that they have, in the first warmth of their discovery, thought it reasonable to alter the common distribution of dignity, and venture to condemn mankind of universal ingratitude; and what labor can be more useful than that which procures to families and communities those necessaries which supply the wants of nature, or those conveniences by which ease, security and elegance are conferred."

"This is one of the innumerable theories which the first attempt to reduce them into practice certainly destroys. If we estimate dignity by immediate usefulness, agriculture is undoubtedly the first and noblest science; yet we see the plough driven, the clod broken, the manure spread, the seeds scattered and the harvest reaped, by men, whom those that feed upon their industry, will never be persuaded to admit into the same rank with heroes or sages; and who, after all their confessions which truth may extort in favor of their occupation, must be content to fill up the lowest class in the commonwealth, to form the base of the pyramid of subordination and lie buried in obscurity themselves, while they support all that is splendid, conspicuous or exalted."

Peerless woman, in all her high and holy influences, has contributed to give dignity to the pursuits of agriculture.—Throughout the succession of time in all civilized nations, she has been man's solace in every condition of life, and to no class of men more eminently than to the cultivators of the soil. It is in the domestic circle of the farmer, that woman shines in all her glory, guiding the distaff, or leading lisping infancy in prayer. But it is not to the farmer alone, that she is the richest of all temporal blessings—her hand is ever open as day to melting charity—her approbation gives rapture to the statesman and the philosopher—her love animates the warrior on the field of battle—her heart is often an altar dedicated to the service of the living God, and her bosom is as the balm of Gilead to the wounded spirit in the hour of trouble.

But if the testimony of men of science and of patriots in all ages fails to recommends the pursuits of agriculture to our favorable consideration, there is intrinsic merit in the profession itself to command our unqualified regard. It is the nursery of patriotism, of wealth and of strength to the state. All writers on political economy speak of the farmer as the "productive class," and all others as the "unproductive classes," and whilst he is creating materials, nearly all other occupations are employed on pre-existing materials. If these views of the general value of the agricultural interest be acknowledged, how much more impressive will they be regarded in reference to our own state, where the products of the soil enter so pre-eminently into the sources of her prosperity. We are in a latitude so peculiarly blessed as to unite the growths which belong to a northern and a southern climate. The tobacco of the south is found by the side of the hemp of the north, and the grass of the north grows luxuriantly by the side of the corn which flourished best in the south. This happy concurrence of climate meets upon a soil of unparalleled fertility and of irrepressible energy; presenting just the undulations in surface which protects it alike from baking or of washing in the cultivation. The corn and grass of this rich region contribute, in the character of provisions and live stock, mainly to the supply of the cotton planter of the south, who, in his turn, supplies the raw material to the manufacturer of the north, who, in his turn, with the merchant and the seaman taking it to market, is fed chiefly by the products of our soil; so that in the circuitous operations of labor and of commerce, Kentucky with the other states of the west, feeds all the operatives of the north and of the south. How dignified, then, should be the pursuit, and how controlling the interest which effects these high objects. But with a soil and climate so inviting, we do not realize from our lands half the product which is found in the northern states, where the cold soil and rock surface is made to yield to the influence of scientific labor; and without a prospect of improvement in the character of our husbandry, we are in danger of being exposed to the remarks of Solomon, in regard to the slovenly farmer. "I went by the field of the slothful, and lo it was all grown over with thorns, and nettles covered the face thereof, and the stone wall was broken down." May we not, however, hope that a better day is dawning upon us in all that relates to the means by which the physical as well as intellectual resources of our country may be developed, and that in view of all the considerations which have been addressed to the pride of the farmer, he may be led to aim at a standard better calculated to elevate him in public regard?

In contemplating the causes which in our own country have led to the low estimate heretofore placed upon the pursuits of agriculture, we cannot fail to ascribe the principal agency to the disrepute in which manual labor is held by those who have been educated for the so called learned professions. Even the merchant considers himself as occupying a higher grade in society, although he is but the *teamster* who is employed in transporting and exchanging the surplus products of the farmer, who creates the raw material, and in bartering the articles of the mechanic and manufacturer who exerts his labor in preparing the raw material for the market. The standard of the farming character suffers injury from the common opinion which attaches to his profession, the want of any intellectual culture or any refinement in manners; and although we may deplore and condemn this unworthy prejudice towards the employment which is intrinsically the most respectable, we have reason to confess that too large a portion of those engaged in the cultivation of the soil seem by their conduct to attach little importance to these requisites of character. If as a profession we do not occupy in the community, the attitude of intelligent farmers and accomplished citizens, we have to ascribe the result, in a great degree, to our neglect of the means which would elevate us in society. We have, heretofore, discarded all connexion between science and art as applied to agriculture, and by the neglect of general education, have allowed other professions to assume and to occupy the position to which we are entitled. We have disregarded even the proper measures for training our sons to the exercise of their most exalted privileges as citizens; and to the apathy and ignorance of farmers, in reference to the fundamental principles of public policy, we may trace most of the political disorders in the state. It is often said when a young man is supposed to be too dull for what are called the learned professions, that he is *then fit for the plough*. Be it our high aim to establish the converse of this proposition; and were the standard of intelligence among farmers as elevated as their employment is honorable, the day may not be distant when the youth who should be found to want the intelligence and energy necessary to make him a successful farmer, will then be pronounced fit only for seeking his fortunes in some one of the "unproductive"—less dignified—learned professions. With this high object constantly in view, and by the adoption of the means which will be adverted to in the further discussion of the subject, the cultivator of the soil may hope to resume the proud attitude which the nature of his profession as well as the approbation of ages has assigned to him.

In attempting to examine the subject with a view to legislative encouragement, I find myself surrounded by a multitude of imposing facts in our own history and in that of other nations in relation to this great interest, all calculated to deepen conviction as to the necessity of arousing the apathy of farmers, of vindicating the dignity of their profession, and of guiding public sentiment to an appreciation of the fundamental cause of national prosperity.—*(To be continued.)*

Circular on Common School Education.

To his Excellency the Governor of   and the members of the Legislature of that State.

Fellow Citizens—"At the ninth annual meeting of the American Lyceum, held in the city of New-York, on the 3d, 4th and 6th of May 1839, the following resolutions, proposed by Professor Brooks of Massachusetts, were maturely considered and unanimously adopted: viz.

"*Resolved*, That it is expedient to hold a National Convention for one week in the "Hall of Independence" at Philadelphia, beginning on the 22d of November next at 10 o'clock A. M. for the purpose of discussing the various topics connected with elementary education in the United States.

"*Resolved*, That a committee of five be appointed to request the Governor (and, if in session, the Legislature) of each state in the Union to invite the friends of education in their state to attend the convention." (*Copy of records.*

The undersigned, having been appointed to form the committee, do now in obedience to their instructions respectfully address you on this paramount subject.

The American Lyceum, in taking measures to carry into effect the above resolutions, expresses its deep anxiety for the proper physical, intellectual and moral culture of every child in the United States. It is ascertained that as many as nineteen out of twenty children, who receive instruction, receive it in the common schools. These schools therefore must be with us the hope of civilization, liberty and virtue. To elevate them so as to meet the wants of our republic is the high and single aim of the convention. Parties in politics and sects in religion will not for a moment be recognized in any form. No power will be vested in the Assembly. It will be, we trust, a company of philanthropists, patriots and christians, coming together in the spirit of an expansive benevolence, to consult for the highest good of the rising generation; and whose deliberations and results, when published to the country, will bring the great cause of education simultaneously before the several states in a form for enlightened, definite and successful action. As subservient to this humane and patriotic object, we would suggest a few among the many topics which will demand the consideration of the meeting: viz:

How many children are there in each state, who, according to the laws of that state, should be under instruction?—How many of this number are found in the schools? What is the condition of the common schools in each state? What is the organization of the school system? What branches of knowledge should be taught in our common schools? What should be the character of our common school books? How may school apparatus and school libraries be made most useful? In what branches should instruction be given orally, and in what degree? What should be the qualifications of teachers? Are normal schools (or seminaries for the preparation of teachers) desirable? On what plan should they be established? Is a central normal school for the Union desirable? Should it be under the direction of Congress or a society of citizens? What connection should the common schools have with academies, colleges and universities? What models for school-houses are best? Will a "Board of Education," established by each state, afford the best supervision and secure the highest improvement of the schools? How can itinerant teachers and lecturers best supply destitute places? Is a national system of instruction desirable? How should a school-fund be applied? In what part of each state has the greatest progress been made in elementary education? How may school statistics, which must be the basis of legislation, be most easily collected? What features of the systems now in operation in Holland, Germany, Prussia, France and Great Britain, may be most usefully adopted in this country?

Fellow Citizens—The discussion of these and kindred topics will probably elicit a mass of information the importance of which cannot be easily overstated. We would therefore urge those, who shall attend the convention, to come prepared for making known the valuable facts they can gather.—Believing that all the talent of a country should be so tempted forth, by judicious culture, as to bring it into profitable and harmonious action; that it is important to the public good as well as to private happiness that we should receive the requisite supply of useful information; and that each faculty which the Creator has implanted in childhood should be developed in its natural order, proper time and due proportion, we invite you to secure the attendance of delegates from your state prepared to promote this first duty of our republic—*the education of our youth*. Believing that our country must look to intelligence as its defence, and to virtue as its life-blood; and that the plan now proposed, originating in the most enlightened views of freedom and humanity, will be the first in a series of means for securing the greatest good to future generations, not only among us, but to our sister republics, the Lyceum desires to bring into a focus all the light which can be collected in our land. Some of the most distinguished gentlemen in several states have promised to be present; and we would suggest the expediency of inviting the members of Congress (who will be on their way to Washington about the time of the meeting) to join the convention.

With the most heartfelt good wishes for the success of every effort for the benefit of the young, both in your state and throughout the Union, we are your friends and fellow citizens,

THEODORE FRELINGHUYSEN, of New-Jersey.
CHARLES BROOKS, of Massachusetts.
JOHN GRISCOM, of Pennsylvania.
HENRY R. SCHOOLCRAFT, of Michigan.
THEODORE DWIGHT JUN. of New-York.

New-York, June 1839.

P. S. We respectfully invite each editor of a newspaper in the United States to give his patrons the opportunity of reading the above circular; and to add this postcript as recording our sincerest thanks for his friendly co-operation.

On the use of Lime.

Bloomsbury Plains, Somerset Co. July 16th, 1839.

Dear Sir—According to your request I will give you my experience on the use of lime. I will first describe the soil of my farm, which is a mixture of clay and a fine calcareous looking sand, with a yellow clay bottom. In 1837 I purchased 200 bushels of slaked stone lime, at 12 cts. per bushel; as it was the first I ever used I was determined to give it a fair trial, and to ascertain its true value. I walked out to my field and laid off one acre of poor worn out land, which did not produce more than 1½ barrels[*] of corn to the acre, and a large part of that hardly saleable. In October I put on 50 bushels of stone lime to the acre, with a tolerable covering of coarse grass, and ploughed it under and let it lie until the next April; then cross-ploughed and planted it in corn: the ground appeared very mellow, and I could see a considerable difference in the color. At the period of harvesting my corn I was anxious to know the result—I gathered the corn and measured it up; the result was 4 barrels of corn to the acre, or 20 bushels of sound corn, weighing 59½ pounds per bushel. I then set down to make a calculation to see what profit I derived from my lime. It is as follows:

20 bushels corn at 75 cts....................		$15 00
Fodder worth..........		3 00
		$18 00
Cost of 50 bushels lime, at 12 cts......	$6 00	
Hauling...............................	1 00	
		7 00
		$11 00
What it produced before liming:—7½ bushels corn at 75 cts.—fodder $1.50, ...		7 12½
Clear profit,...........		$3 87½

And *leaving my land worth three times as much as it was before the application of lime*. Well, I had 150 bushels left—I put it into a compost with barn-yard manure, such as pine tops and straw litter from cattle—In the spring manured with my compost in the hill, which acted admirably, equal to stable manure. I have tried the lime on almost a bald surface, and I could perceive scarcely any benefit. I think it will not act well without some vegetable matter. My opinion is, that it acts as a stimulus, and rectifies the unproductive properties of the soil. I tried oyster shell lime—I took a piece of ground I thought would produce about 2½ barrels, and applied 100 bushels oyster shell lime with some coarse manure. I did not measure the corn, as I was hurried, but thought it would gather 70 bushels per acre. I will leave you to describe the present crop, as you were an eye-witness to it. Yours respectfully, MATTHIAS B. TOADVINE.

Facts for Farmers.

[*From the Boston Cultivator.*]

It is a fact that some cows will make three times as much butter as others of the same size and with the same keeping. It is a fact that some breeds of swine will make a ton of pork out of half the keeping which is required for other breeds.

It is a fact that some ploughs require twice as much team as others and yet do not perform the work so well. It is a fact that some farms of fifty acres produce more than some other farms of one hundred acres.

Is it not worth our while to make inquiry into the causes of these differences and to devise a mode of equalization; And first, as to our breeds of cattle. We will make no over statements. We know there is abundance of testimony that we have native cows which will make more than fourteen pounds of butter per week each, and we all know we have a great number of cows that will not make five pounds each. With these facts staring us in the face shall we not cast out those that will not pay the expense of keeping and introduce better breeds?

We would not be understood as making comparison with any foreign breeds of cattle. Those who prefer them may make the trial, and may improve by crossings; but we would improve our native breeds and select the very best. There can be no doubt of the practicability of producing a herd from our native stock that shall in a very few generations be sure to prove of the true blood of the ancestors. We have yet made no trial in this country, but knowing what has been done elsewhere, we can now proceed with confidence, having our path lighted by lamps that have gone before.

The course of commerce between Massachusetts and the interior has for many years been unfavorable to the improvement of our neat stock and of our swine. In the vicinity of our cities we have found it more profitable to slay all and eat all our young neats, at an early age, than to rear them; while in the interior, where keeping was cheap and there was no market for veal, the whole progeny of the neat cattle has been reared without the least regard to symmetry of form or promise of excllence. All must perceive that by proceeding in this manner we can make no improvement in our stock.

But a better era begins to dawn upon us; for since it is found that the most excellent of our own cows will command a price bearing some proportion to the good qualities of the animal, the best will be snatched from the butcher and reared; and inferior animals from the interior will bring only such prices as may justify their purchase for beef. The whole tendency of the operation will be in favor of selections, both here and in the interior, of the best animals for rearing.

But we hope and trust we shall not be content with this slow mode of approximating to a perfect breed of neat stock. Since farmers are becoming convinced of the superiority of the best of our native stock over the poorest, they will lend their aid to those who shall begin in earnest to rear only from the best animals.

We are fully satisfied that no branch of farming could be pursued to greater profit, even within a few miles of Boston, than that of rearing the best of neat stock that can be selected from our native breeds, and we are pleased that one gentleman at least in the neighborhood of Boston is determined to prove what may be done by crosses of our very best native cows with an English bull of the Ayreshire breed which is of fine form and was not selected for his great size but for his good qualities.

We sincerely hope others will be induced to imitate his example, so far at least as a selection of our best native stock is concerned—and that not only the females but the best males will be selected and kept from other herds until we can be supplied with an improved breed that shall rival the best that has ever been reared.

By breeding from the very best males and females only, we may be quite certain in a short time to raise up a perfect stock. We well know "a good cow may have a bad calf," but ten good cows with a male of the right breed will have eight or nine good calves, and the descendents of these will be more likely to be of the true breed, and so on; the farther we progress the more sure we may be of a correct result.

And what an acquisition to the farmer and to the community to possess herds that will give us thrice the milk which our present stock supplies.

The average expense of keeping a cow on hay and grass in the vicinity of Boston for a number of years past may be stated at not less than thirty dollars each. The average value of her milk made into butter may be 140 weight, or seven pounds per week for twenty weeks,—or at nine quarts per day, 9 times 140 equals 1260 quarts, and this at four cents per quart equals $50.40. Thus the butter to equal the milk should bring thirty-six cents per pound.

We have yet counted but twenty weeks milking, but with good keeping cows should be milked not less than forty weeks, and if turnips and grain are fed out the last twenty weeks will give half as much as the first twenty. The produce in milk might then be worth $75.00—in butter, at the common market price, it would be one third-less, though the nicest premium butter has often brought more than this milk would amount to.

We think it quite feasible to rear cows that will give double this quantity of milk or butter, and how valuable must be such stock?

Beet Sugar.

[*From the New-England Farmer.*]

We perceive by a recent number, that our neighbor the publisher of the Yankee Farmer, proposes forming an association for the purpose of ascertaining the practicability and advantages, if any, of the manufacture of sugar from beets in this country, by the latest and most improved methods.—Especially, he is desirous of determining whether it can be so managed, as has been represented, that every farmer's family in the country may by a simple household practice, supply their own wants. We most heartily wish him all possible success. How far the calculations which he has given to the public in relation to this matter, are to be relied on, we are not able to say. But the funds asked for are a small affair compared with the importance of the object in view; and, divided as they will be, cannot fall heavily, even if the project should fail. But success is highly probable.

The sugar beet is beginning to be much cultivated in various parts of the state. We have seen considerable fields of it in many places: and trials of it as feed for cattle and swine have served to bring it into favor. A company is prosecuting the cultivation of it, as we have been informed, to a large extent in Michigan, with a view to the manufacture of sugar.

---

[*] Seven and a half bushels.

One spirited individual has informed us that he has one hundred acres in that state devoted to sugar beet. The present year, therefore, will probably decide what can be done.

There are facts in regard to it, now existing in France, which we find it difficult to reconcile to statements which are constantly made in respect to the manufacture in that country. The first is, why if the cultivation and manufacture are as profitable in that country as is represented, they require so heavy a duty upon colonial sugar in order to protect the manufacture of beet sugar. The second is, why if the new methods recently discovered are successful, and by them the sugar can be produced at a low rate, they are not at once adopted, and the government protection rendered unnecessary. An intelligent gentleman, sent out by the Northampton Beet Sugar Company, for the express purpose of obtaining all necessary information in relation to the matter, informed us that Shutzenbach's method upon trial in France was not approved. Fleischman in his interesting report to Congress on this subject, states the discovery of a method of extracting the sugar from the beet, by which a considerably larger amount of sugar was obtained than by Shutzenbach's method, at a less expense, and in a way which would place the manufacture within the reach of every farmer's family in the country. It is now full time that we should have received the results of experiments made by this method. Probably they have been made and others are in possession of the results. We have not been so fortunate. Shutzenbach's method, as we have been informed by persons who were not proprietors in the concern, has been tried at Northampton with success. We have seen a sample of the sugar made there, which promises well; but can give no particulars.—More than a year since, we mentioned the discovery of a method of extracting and manufacturing the sugar, by a gentleman at Stoneham, in the vicinity of Boston, which promised the advantages of general practicableness, small expense and a large per centage of sugar from the amount of product. We saw the sliced and dried beets; the mode of obtaining the syrup; the chrystallization of the syrup, and the sugar perfected, but not refined—certainly a beautiful article. For the amount which could be obtained from the beet by this process, and which was represented to be from eight to ten per cent, and for the expense required in the extraction and manufacture, we relied upon the testimony of the operator, whose integrity is beyond a question. We deemed it a most important discovery, and after a patent for the manufacture had been obtained, we had great pleasure in announcing it. We thought the vessel had not only entered the harbor but actually reached the wharf; and were quite disposed to throw up our hat with the farmers and give three cheers. But it seems to have been a phantom ship or a sort of "flying Dutchman," for we have not been able to obtain a word further on the subject.

The matter deserves all the attention which any among us seem disposed to give to it; and we wish our neighbor all the beet sugar he can need in his tea and coffee the rest of his life, sweet creature as he must become, if his useful project should prove successful. H. C.

Red Giant Goliah Rhubarb.*

In the market gardens around London, a large species of rhubarb is extensively cultivated, with which the various excellent markets of the metropolis are well supplied; but beyond the range of a few miles, the particular kind to which we would direct the attention of our farming friends, is comparatively little known—the generality of country gardens being disgraced with a root or two of dock-like plants, with stalks no thicker than a finger, fibres like a whip-cord, and a flavor!—Uh! No wonder so few persons, *thus possessed*, should like rhubarb tarts! No wonder they disguise the taste with shrivelled apples just going out of season, or gooseberries just coming in! The noble plant which we would recommend to every living being who owns a patch of garden ground, is as superior to the old fashioned nauseous plant just mentioned, as our cultivated celery is superior to the rank wild weed of the same name growing by muddy ditches. One would be led to suppose, that, from the rarity of the giant rhubarb, it was difficult of cultivation, tender and troublesome to manage; whereas it is as easily propagated as any other perennial vegetable; is so hardy that no degree of frost which we have ever experienced, will injure it; and of all esculents for pies and puddings, it is the most readily prepared. It is so prolific that half a dozen roots would keep a small family constantly supplied, during four months of the year; that is, from the beginning or middle of April, (according to the forwardness or backwardness of the season,) until the beginning or middle of August. We have known instances of this, *fruit* must we style it? being preferred to all others for the purpose of pastry, throughout the summer, even where fruits of every kind abound. We have known stalks of the Red Goliah Rhubarb to measure six inches in circumference and nearly two feet in length, so that only one of them has been required for a pudding: so delicate and soft, too, is its texture, that as soon as it arrives at the boiling point, it becomes a fine pulp, and is already sufficiently cooked. As a garden production for culinary purposes, it is certainly invaluable—being in perfection precisely at that season when apples become tough and scarce, and before gooseberries have made their appearance. Its flavor is so delicate, that it ought not to be mixed with any other ingredient than sugar; and on no account should it ever be peeled.

The Red Goliah Rhubarb may be propagated either by sowing the seeds or purchasing young roots of one year's growth, and planting them during the spring months in a good rich soil. In the former case, that is, if the seeds be sown, they are to be transplanted in a few weeks, and in the following year their stalks will be large enough to pull. If roots be obtained and planted in March, the plot will be available in a month or six weeks. No further care is requisite than to manure the bed in the autumn after the leaves have decayed. To those who are unaccustomed to the plant which is the subject of our eulogium, it may be as well to mention, that the stalks should never be cut from the bed, but wrenched sideways with a sudden twist, when the whole stalk comes away at its junction with the root—round, flat, clear, and white as milk.

As soon as the growth becomes vigorous, each root sends up a flower stalk, which will readily be distinguished from the leaf stalks; these must be pulled away, and only one left (if it be intended to procure seed,) and this plant should be less used than the others, if at all, during the season. The leaves are enormous; we have measured many that have been four feet long and three and a half wide. The roots, too, are gigantic—so large that, in the course of three or four years, a single root, when digged up, would fill a wheelbarrow: hence the plants require a wide space—say five feet apart every way.—*Edinburgh Quarterly Journal of Agriculture.*

London Lactaries.

To those unacquainted with this vast metropolis, and the almost incalculable amount of supplies the number of its inhabitants must necessarily require, the article of milk must appear not the least striking.

The writer of this little notice—an invalid, spending an interval in the vicinity—is enabled to give the following description of Laycock's Dairy at Islington.

The lactary covers a space of sixteen acres, including the layers, grain-pits, rick-yards, &c. &c. It contains nine cow-houses, each about one hundred and forty feet in length, by twenty-four feet broad, either of these contains sixty-four cows, thirty two on a side. There are also fatting-pens, and an infirmary for such of them as may happen to require temporary separation; these instances, however, considering the great number kept, and the artificial mode of treatment, are but rare, the writer being assured by the resident veterinary surgeon, Mr. Stavley, to whose politeness the former is indebted for his information, that nearly the *only* inconvenience felt is, that arising from lameness. The animals, all of the finest description, are constantly kept in their houses both day and night, in the summer season only being turned out for a few hours daily into the layers. Cows are rarely kept here longer than twelve months, during which period they are regularly milked, and what may appear extraordinary to those ignorant of the management, the process of fatting goes on with the milking; so that by the time they become what is termed "dry," most of them are fit for Smithfield, and but few of the number (six hundred constantly kept) require "stalling" after the period of milking is at an end.

The writer has viewed several in an extraordinarily high state of condition, (almost fit for a Christmas show) at the time the Cambrian and Hibernian women were sitting upon their stools, each exercising with inconceivable volubility her vernacular tongue, and "filling her milking pail."

This number affords twelve hundred gallons of milk per diem, upon the average; it is taken away at an early hour of the morning and afternoon by the venders, who purchase here to retail in the metropolis.

The average worth of each cow is about 18*l.* which, assuming the number kept always to average six hundred (the minimum rather than otherwise) gives a capital of 10,900*l.* always afloat to stock this stupendous dairy with cows only.

Their feed consists of grains, mangold wurzel, the Swedish turnip (the latter for fatting), and hay; at the rate of

1 bushel of grains,
56 lbs. of mangold wurzel, or turnip,
12 lbs. of hay,

to each; or

600 bushels of grains,
15 tons of wurzel and turnip,
3 6-28 tons of hay,

per day, to the total number.

The quantity of butter made here is, for an obvious reason small; and rarely exceeds 100 lbs. per week.

The number of pigs kept here is about 400; some bred, others bought in, but all fatted here.

Forty horses are always required, and constantly employed upon the dairy.

The layers are capable of receiving 1,600 head of fat cattle, exclusive of sheep; and the average number for Smithfield market, resting here weekly, is 800; the charge of layerage being 3d. per head, and fodder at the rate of 3s. per 56 lbs. or truss.

Such is *one* of the London Lactaries—there are many of them, some of larger, several of equal, and a few of inferior extent.

From this brief description of one, however, some idea may be formed of the consumption of this nutritious article of our food, but which, nevertheless, forms so inconsiderable a portion of it, called milk. J. R.

The Danger of Fashion.

I think that a slight examination will convince any one that the present fashions and modes of dress are far more injurious to health than any other cause whatever. The human system, when fully developed, and healthy in all its parts, is a highly complicated and most beautiful fabric; composed of a number of distinct organs, each acting in the most perfect harmony with every other; and each performing its own separate and independent function with a nicety and precision which no art can imitate. The lungs, for instance, are formed by nature with a capacity just sufficient to admit the requisite quantity of air for purifying the blood and no more. Hence, if the chest is contracted, and the lungs in any degree compressed, the blood is not sufficiently purified, and unless the compression is speedily removed, ill health, nervousness, &c. is invariably the necessary consequence. And the same may be said of every other important organ. How, then, can a mother expect her daughter to grow up in health and vigor, when before she has passed the tender age of seven, she is *corsetted* and placed in a snug dress for the avowed purpose of making her "grow trim and of a beautiful form." Is it not apparent to every observer that by these means the chest is trammelled in all its movements—the lungs thereby prevented from their natural degree of expansion, and consequently the blood is imperfectly purified; the heart, too, is unduly compressed, the stomach crowded downward, and the muscles of the chest and back prevented from becoming fully developed? Now the consequence of all this is, that in a few years the skin becomes sallow; the heart palpitates, there are frequent congestions of the lungs; dizziness, and perhaps pain in the head; frequent pains in the back and side; general debility and nervousness; and perhaps more or less distortion of the spine, the very thing above all others which the kind mother wishes to avoid. But the mandates of fashion are irrevocable, and consequently the same mode of dress is persisted in. Now the doctor is called, and a course of medicine endured; then a few weeks or months at Saratoga, or peradventure a trip to the south. She returns perhaps partially restored; marries, lingers a few years as a mother, and then sinks into an early grave—leaving a few feeble and delicate children to the cold charities of the world. Dear reader, have you never beheld a case of this kind? Alas, it is but the brief history of too many. Indeed, how can a young lady expect to receive any benefit from exercise while her arms are bound down, and her waist contracted by means of corsets, belts, &c. in such a manner as totally to prevent all natural action of the muscles of the chest and back? She may indeed walk, but it will only serve to throw the blood with more force into the already compressed and engorged lungs, and thus increase the nervousness, palpitations, exhaustions, &c. Let me not, however, be understood as undervaluing proper exercise, for I am only endeavoring to show that attempts at exercise, while the body is restrained in all natural movements is a mockery, and worse than useless. Neither would I confine my remarks to the females alone; for I have found that many young gentlemen, especially in our cities and villages, make their vests, &c. answer precisely the same purpose as the ladies' corsets and belts.—*Christian Advocate.*

Beet Sugar.

The editor of the Yankee Farmer is drawing the attention of the public to the importance of introducing into this country the manufacture of sugar from the beet, and contemplates visiting France, if he receives sufficient aid from those who feel an interest in the matter (of which, from a recent statement, there seems to be a probability will be accorded him,) in order that he may more fully be enabled to make an experiment that will demonstrate its practicability, by the introduction of a new process recently adopted in France, by which 180 lbs. of white refined sugar is obtained from a ton of beets—2000 bushels is 60 tons, and the product of 60 tons will be 10,000 lbs. of sugar. The editor makes the following calculations as to the expected result of the experiment on the data here given.

10,000 lbs. white sugar worth at least 12 cts.	$1,200
6 tons pomace, ...	30
Machinery and fixtures, ...	300
Premium from Massachusetts State Agricultural and other societies, ...	200
Massachusetts state bounty, ...	300
	$2,030

The editor has no doubt of the entire success of the experiment, and gives a statement from the report of the "*Societie d' Encouragement,*" from which it appears that farmers in France make sugar for 4 cents per lb. and that two young men, who invested 500 francs in the business, manufactured 100 lbs. white refined sugar daily, worth in that market 16 cts. a pound, and estimate the cost of their sugar to them as follows:

One ton of beets, ...	$3 20
Cost of cutting, drying, and extracting the sugar, ..	4 00
Total cost for 180 lbs. of sugar, ...	$7 20

—*American Farmer.*

Hoeing Corn late will frequently protect it from frost.

Mr. Editor—If an individual has, by a simple experiment, or long experience, discovered any thing of practical utility, calculated to benefit his fellow men, and the community, I hold that it is his bounden duty, as well as his privilege to communicate such facts, that others may participate with him in the blessing; and more especially when such knowledge can be imparted and not operate in the least prejudicial to himself.

I have been a cultivator of the soil from my youth, and for thirty years never failed in a crop of ripe corn.

My method has been, when, in the fall there are indications of frost and my corn in danger of not being ripe, I muster my hands and commence stirring the earth about one inch deep, with our hoes, having learned that stirring the ground, and loosening its surface, would more readily cause it to absorb the rays of the sun, and produce more heat than it would if it had not been disturbed.

I once had a piece of corn, about three acres nearly surrounded with woods, and much exposed to the frost. Before it was ripe there was every appearance of frost, and I commenced hoeing it. The sun shone clearly upon that and the following day, and the night succeeding there was a very severe frost. Early the next morning, I started out to examine its effects upon my corn, the fields and fences were white, and as I went through my neighbor's corn I found it stiff and consequently dead. I entered my field and although frost carried every thing immediately around it, my corn was not in the least injured, but was covered with a heavy dew. I obtained a good crop, while my neighbor's was entirely cut off.

If you consider the above worth a place in your paper you may publish it. I. L.

West Hallowell, June 24, 1839—*Maine Cul.*

This *is* "worth a place," and there is practical philosophy for the reason of it. Stirring the earth opens the pores; the consequence is, a greater collection of moisture upon the plants, which withstands frost.—*Ed. Cul.*

Infant Schools of Agriculture and Horticulture in France.

An establishment has lately been formed in the department of Gard, for giving practical lessons in horticulture and agriculture to children. Full success has attended the attempt, and the example is about to be followed in other quarters.—Two acres of empty land were divided into nursery, corn land, flower gardens and kitchen gardens. All the inhabitants of the neighborhood assist in conveying instruction to the children, or in smoothing their progress. A regular instructor is appointed, who gives lessons on gardening, in which he is aided by the cultivators who live near. The

---

* This valuable plant was introduced into the Albany Nursery four years ago. Twelve stalks, shown at the late Horticultural Exhibition, weighed 12¼ lbs. It *is* the best fruit for pies. It is perennial, hardy, and, on rich ground, is as certain a crop as horse radish.—*Cond.*

Mayor and the Curé employ their influence in putting aside such obstacles as prejudice or long established custom might throw in their way. The forest ranger is useful in pointing out the exact state of the laws respecting trees, and the proprietors of land supply seed, corn and flowers. Half of the produce is given up to the instructor, a portion of the other half is distributed as a recompense amongst the pupils, and the remainder is sold to the inhabitants of the village. After some time a considerable sum is raised from these sales, the money is laid out in defraying the general expenses, in purchasing tools, in providing seed without being indebted for it to the kindness of the proprietors, and in increasing the emoluments of the instructor. The little farm is thus found to advance rapidly to perfection, and in a short time is the most productive spot of ground in the country; of course it is understood that all the work is done by the pupils; were it otherwise, the object of the institution would be entirely lost, as practical instruction would no longer be given. These infant schools for horticulture and agriculture are on the increase in France.—*Laborer's Friends' Magazine for April*, 1839.

On the Cultivation of Roots, &c.

[*From the Essex Agricultural Society's Transactions.*]

Methuen, February 16, 1839.

Dear Sir—Taking a deep interest as I do in agricultural pursuits; and believing that by interchange of views, and making public our experiments, the agricultural interest may be promoted; I have concluded to comply with your request, and state my success the past season in the cultivation of roots. The land which was last year planted with potatoes, was ploughed and dressed with six cords of green manure to the acre. On the 14th of June, I planted three-fourths of a pound of ruta baga seed mixed with one bushel of plaster of paris, on three-fourths of an acre of land—planted in drills two and a half feet apart. After they came up, I applied six bushels of wood ashes; thinned them out when they were of suitable size for transplanting; hoed them three times; gathered them the first of November, and estimated them at 700 bushels on the piece. I planted half an acre in another piece, on light pasture land, which was last year sowed with oats without manure; it was manured and managed the same as the other piece, excepting the manure was of different kinds. In consequence, as I supposed, of being planted too deep, they came up thinly, and the weather being extremely dry, it prevented my transplanting them. I gathered 250 bushels on the piece; I think that had they come up well, they would have yielded from 700 to 800 bushels to the acre. I think there was one-half difference in the size of the turnips on different parts of the piece, owing to different kinds of manure, but I could not recollect what kind of manure was applied where the turnips were the largest. It would be well to try the experiment, to ascertain what kind of manure is most suitable for them. I commenced plucking the under leaves from the turnips on the first mentioned piece, about the first of September, for my cows, but thinking it might injure the roots, I discontinued about the 15th. When I gathered them I could perceive no difference where the under leaves were plucked off, and where they were not. I think the leaves on that piece, as there was a luxuriant growth, would have kept my eight cows, in addition to running in the pasture, until the last of October. I think the leaves of considerable value, as we have them at that season of the year when stock requires extra feed.

I also raised about 50 bushels of mangel wurzel; had they been planted thick enough, I think their yield would have been nearly the same as the ruta baga; I think they should be planted thicker than ruta bagas, as their tops are not so large; as to their comparative value, perhaps I am not a suitable judge; as I have had but little experience, but I am certain of this, that the hogs like mangel wurzel much better than turnips. I am of the opinion, however, that both kinds are much more profitable to raise for stock feeding than potatoes.

I will also state one or two experiments in regard to apples. I have for the last four years fattened a beef for my own use each year, mostly on apples. The first of October. 1836, I dried a cow which was in ordinary flesh, and commenced feeding her with apples the first of November. I killed her about the middle of January, 1837; the beef was fat and of a good quality; she was fattened exclusively on apples.—The first of November, 1838, I commenced feeding a cow with apples; I think she ate about three and a half pecks per day; about the 25th of December, she refused eating apples, in consequence of their being some rotten. I fed her with ruta bagas until the 9th of January, when I butchered her. The beef was fat, and of good quality, (what I mean by being of good quality, aside from being fat, is, it cooked well, and did not taste like apples, nor turnips, as some suppose,) but tasted like beef. The cow had a calf in the spring, gave a good mess of milk during the season, and I dried her about the 25th of November.

For the last three years, I have kept my hogs mostly on apples during autumn and first of winter, and they have thriven well, but as I gave them some other food, I can make no definite statement. Experiments have been tried by other individuals in my neighborhood with nearly the same success.

I am aware that some of my brother farmers may doubt my statement in regard to the value of apples, (especially those who are fond of cider.) But I would ask them to try the experiment.

You are at liberty make such use of the above statement as you may think proper. Respectfully yours,

JOSEPH HOW.

To J. W. Proctor, Esq. *Sec'y of the Essex Ag. Soc.*

The Farrier.

[*From the Maine Farmer.*]

Try before you buy.—If you meet with a horse you like, and are desirous of buying him, do not fall in love with him before you ride him, for though he may be handsome, he may start or stumble.

To discover a stumbler.—If you go to buy of one that knows you, it is not unreasonable to desire to ride him for an hour. If refused, you may suspect he has some faults; if not, mount him at the door of the stable where he stands; let him neither feel your spurs, nor see your whip; mount him easily, and when seated, go gently off with a loose rein, which will make him careless; and if he is a stumbler, he will discover himself presently, especially if the road in which you ride him be any thing rough.

The best horse indeed may stumble (a young one of spirit, if not properly broken in, will frequently; and yet if he moves nimbly upon the bit, dividing his legs true, he may become a very good saddle-horse,) I say, may stumble; but if he springs out, when he stumbles, as if he feared your whip or spur, depend upon it he is an old offender. A horse should never be struck for stumbling, or starting: the provocation, I confess, is great, but the fear of correction makes him worse.

In the purchase of a horse, examine four things—his teeth, his eyes, his legs, and his wind.

To know his age.—Every treatise on farriery has instructed us to know a horse's age by the mark in his mouth; but not one in five hundred (a dealer excepted) can retain it in his mind. I have endeavored, therefore, to represent it by a plate.

Every horse has six teeth before in each jaw; till he is two years and a half old, they are all smooth and uniform in their upper surfaces.

At two years and a half old he sheds the two middle teeth, (by the young teeth's rising and forcing the old ones out,) which at three years old are replaced by two hollow ones.

When he is about three years and a half old, he sheds two others, one on each side the two middle ones, which at four years old are replaced by two others, which are also hollow.

The sharp, single teeth in horses, begin to appear in the lower jaw when the horse is about three and a half, or four years old. When he is nearly six years old, they are full grown, pointed, and concave in the inside.

When he is four years and a half old, he sheds the two corner teeth, which at five are replaced also with two hollow ones, grooved on the inside, which groove marks the age precisely.

At six years of age this groove begins to fill up, and disappear; so do the hollows of the rest of the teeth, which continue till near seven and a half, or eight years old, when all the teeth become uniformly full and smooth.

Crafty jockies will sometimes burn holes in the teeth, to make them appear young, which they call bishoping; but a discerning eye will soon discover the cheat.

Eyes.—If a horse's eyes are lively and clear, and you can see to the bottom, and the image of your face be reflected from thence, and not from the surface of the eye, they are good; but if muddy, cloudy, or coal-black, they are bad.

Legs.—If his knees are not broken, nor stand bending and trembling forward (which is called knuckling,) his legs may be good; but if he steps short, and digs his toes in the ground, it is a sign he will knuckle. In short, if the hoof be pretty flat and not curled, you need not fear a founder.

Wind.—If his flanks beat even and slow, his wind may be good, but if they heave double and irregular, or if (while he stands in the stable) he blows at the nostrils, as if he had just been galloping, they are signs of a broken wind. Deceitful dealers have a draught which they sometimes give, to make a horse breathe regularly in the stable, the surest way therefore to judge of his wind, is to give him a good brushing gallop, and it is ten to one, if his wind be broken, or even touched, that he will cough and wheeze very much, and no medicine can prevent him doing so.

Cure for a broken wind.—A broken wind may be cured, if the following be applied on the discovery of it:—A quarter of a pound of common tar, and the like quantity of honey; beat them well together, then dissolve them in a quart of new milk; let the horse fast two hours before you give the drench: walk him an hour after, and let him fast two hours; give this drench every second day with warm meat and drink.

A draught-horse.—A horse with thick shoulders and a broad chest laden with flesh, hanging too forward and heavily projecting over his knees and feet, is fitter for a collar than a saddle.

A saddle-horse.—A horse with thin shoulders, and a flat chest, whose fore feet stand boldly forward and even, his neck rising semicircularly from the points of those thin shoulders to his head, may justly be said to have a light forehand, and be fitter for a saddle than a collar. As most horses in the hands of farmers are drawn while they are young, which notwithstanding their make, occasions them to move heavily: if you desire a nimble-footed horse, choose one that has never been drawn.

In buying a horse, inquire into four other things, viz: biting, kicking, stopping and starting.

A horse may be sound, though guilty of all four, which a man can hardly discover by barely looking on him; so I refer you to his keeper.

When you are buying, it is common for the owner to say in praise of his horse, that he has neither splint, spavin, nor windgall.

The Splint.—The splint is a fixed callous excrescence or hard knob, growing upon the flat of the in or out side (and sometimes both) of the shank-bone; a little under, and not far from the knee, and may be seen and felt.

To take it off, shave the part, and beat it with a stick, prick it with a nail in a flat stick, clap on a blistering plaster as strong as you can make it; let it lie on three days; then take it off, and rub the place with half a drachm of the oil of origanum, and as much oil of vitriol, mixed; if the first does not do, rub it a second time with the oils; if you find any remains of the splint, apply a second blistering plaster for twenty-four hours, walk him moderately to prevent any swelling or excrescence from settling.

Most young horses have splints, more or less, and they will occasion lameness while they are coming upon the bone; but after they are grown to the firmness of bones, they do not lame a horse, nor is such a horse worse for use, though he may not look so well to the eye.

The Spavin.—The spavin is of the same nature, and appears, in like manner, on the instep bone behind, not far below the hough. To take it off, beat the bone with a bleeding stick, and rub it; then anoint it with the oil of origanum, tie a wet cloth about it, and with a hot brick applied to it, soak in the oil, till it be dry.

Windgall.—Windgalls are several little swellings just above the fet-lock joints of all the four legs; they seem when felt, to be full of wind or jelly, but they never lame a horse; the splint and spavin always do. They all three proceed from one and the same cause, which is hard riding, travelling too far in one day, or carrying too great a weight when young.

Setting out on a journey.—Whenever you intend to travel, hunt, or only ride out for the air, let your horse's feet be examined sometime before, to see that his shoes are all fast and sit easy on his feet, for on that depends the pleasure and safety of your journey.

Directions for mounting.—Before you mount, look round your horse, to see if his bridle, curb, saddle, and girths, are all fitted in their proper places. Always accustom your horse to stand firm and without a motion, till you are fixed in your seat, and your clothes be adjusted.

Directions for going.—When you would have him go, teach him to move by pressing close your knees, or speaking to him, without using whip or spur; for a horse will learn any thing; and a good quality may as easily be taught him as a bad one.

Corrections ill-timed. Corrections well-timed. An easy rein.—Most men whip and spur a horse, to make him go faster, before they bid him; but it is cruel treatment to beat a generous creature before you have signified your mind to him (by some token which he may be taught to understand,) who would obey you if he knew your pleasure; it is time enough to correct him when he refuses, or resists you. Do not haul his head about with too tight a rein, it deadens his mouth; besides, he will carry you safer, and take better care of his steps with an easy hand, than a heavy one: much depends on the quietness of the bridle hand. Keep your elbows steady, and you cannot hurt his mouth. Again, nothing discovers a bad horseman (even at a distance) so much as throwing his arms and legs about; for it is easiest to the horse and rider, and he can carry you farther by ten miles a day when you sit as steady upon him as if you were a part of himself.

Employment of Mineral Tar or Pyroligneous Liquor, for the protection of Walls of Masonry or of Mud.

When the walls are thoroughly dry, towards the end of summer (having previously been either newly built or put into a state of thorough repair), they are to be coated over, once, twice, or thrice, with the tar. The last coat, immediately when put on, may be powdered with sand; and this, when solidified, may be whitewashed. In France, earthern walls, and the walls of court yards and terraces, are treated in this manner, and so rendered of great durability.—(*Annales des Ponts et Chaussees,* as quoted in the *Frank. Jour.* vol. xxii. p. 284.)

To prevent Horses being teased by Flies.

Take two or three small handfuls of walnut leaves, upon which pour two or three quarts of cold water: let it infuse one night, and pour the whole next morning into a kettle, and let it boil for a quarter of an hour;—when cold it will be fit for use. No more is required than to moisten a sponge, and before the horse goes out of the stable, let those parts which are most irritable be smeared over with the liquor, viz. between and upon the ears, the neck, the flank, &c. Not only the lady or gentleman who rides out for pleasure, will derive benefit from the walnut leaves thus prepared, but the coachman, the wagoner, and all others who use horses during the hot months.—*Farmers' Receipt Book.*

Efficacy of Stinkweed.

[*From the American Farmer.*]

Sir—A lady has caused to be published in the Chronicle, that hogs-lard rubbed on a bedstead with a piece of woollen cloth, will prevent the bed-bug from infesting the bedstead.

An extract obtained by stewing Gympson or Jamestown weed,* in fish oil, and rubbed on bedsteads and posts, and the wash-boards in a lodging room, is found from practice, to destroy bed-bugs and other insects that infest a room during the warm summer months. During the excessive heat and drought of last summer, a lodging room in the third story of an old inhabited brick house on St. Paul's street, was infested with bed-bugs. The extract of Jamestown weed stewed in common fish oil was applied; it destroyed the bugs, and no musquitoes annoyed the person who slept in it. The moth fly and common flies did not appear in the room. Spermaceti whale oil had better be made use of instead of the common fish oil. The South Sea Islanders anoint their bodies with fish oil in order to protect them from the annoyance of insects.

An extract of Gympson or Jamestown weed, made by stewing the leaves and tender stalks in common fish oil, might be applied to seed wheat and corn, with a brush, stirring the heaps, to be kept in a close room ten or fifteen days before sowing or planting. It would be offensive to birds and insects—The germ of the Hessian fly and other insects might be destroyed by it. The quantity of oil required would be inconsiderable; it now sells at 46 cents per gallon.

The extract might be applied to advantage on the roots of peach trees when replanted, and an application of it might be applied to seeds generally.

The extract destroys lice and other insects on animals.—A little rubbed on the head and back of sheep when sheared, would prove advantageous.

Metallic and vegetable poisons are much used in spirits, which are greatly objectionable, on account of the danger of keeping the solution in families. Any poison in fish oil would not be dangerous.

Gympson leaves and tender stalks, stewed in any oil or grease of any kind, until the leaves and stalks become soft, then strained and squeezed through coarse linen fabrics, gives an extract which will keep good for use a number of years. A.

[The above is from a highly respectable source, and should any of our readers make any experiments on the hints given therein, they might render a service to the public by making known the results.]

Preserving Wood by Lime Water.

We find the following article in (English) Mechanics' Magazine.

"Sir—I some years ago called the attention of the readers of your instructive periodical, to Sir Charles Steward Menteith's (of Closeburn, Dumfrieshire,) simple *unpatented* method of preserving timber; I think it so valuable a process that it cannot be too often published. It is as follows:—After cutting the timber to the size it will be wanted, it is steeped in a pond of lime and water for a fortnight, or more or less time, according to the size of the wood. Sir Charles has now some farm-buildings on his estate, the timber of the roofs of which is the common young Scotch fir, but having undergone the *lime water* process, it is as sound, after a lapse of forty years, as the day it was put up: the same timber, under ordinary circumstances, and in similar situations, would rot in from three to seven years. The carpenters find, in working the wood thus treated, that the edges of their plane-irons soon become dull; on examination, it is found that the acid contained in the wood is chrystallized by combining with the alkali of the lime. Yours faithfully,

"ARTHUR TREVELYAN.

"*Wallington, Newcastle, Tyne, 7th May*, 1839."

Use of Lime.

Lockhart, in his Life of Sir Walter Scott, relates the following anecdote:

"There see," he continued, "that farm there at the foot of the hill, is occupied by a respectable enough tenant of mine; I told him I had a great desire for him to try the effect of lime on his land. He said he doubted its success, and could not venture to risque so much money as it would cost. Well, said I, fair enough; but as I wish to have the experiment tried, you shall have the lime for the mere carting; you may send to the place where it is to be bought, and at the term day you shall strike off the whole value of the lime from the rent due to me. When the pay day came, my friend the farmer came with his whole rent, which he laid down on the table before me, without deduction. "How's this my man; you are to deduct for the lime, you know." "Why, Sir Walter," he replied, "my conscience will not let me impose upon you so far—the lime you recommended me to try, and which but for your suggestion I would never have tried, has produced more than would have purchased the lime half a dozen times over, and I cannot think of making a deduction."

Young Men's Department.

Chemical Catechism—Chapter VIII.

[*From Parkes' Chemical Catechism.*]

OF SALTS.—[CONTINUED.]

What is meant by the DELIQUESCENCE *of a salt?*

Some salts have so great an affinity for water, that they absorb it with avidity from the atmosphere. Such salts thereby become moist or liquid, and are said to deliquesce, by exposure to atmospheric air.[*]

What is meant by the EFFLORESCENCE *of a salt?*

Some salts, having less affinity for water than atmospheric air has, lose their water of crystallization by exposure, and readily fall into powder: such salts are said to effloresce. The crystals of sub-carbonate of soda and of sulphate of soda are good examples of this property.

Are salts capable of any other changes besides efflorescence and deliquescence?

Yes: salts have the properties of solubility[†] and fusibility.

What is meant by the SOLUBILITY *of a salt?*

It is its capacity to unite with and remain dissolved in water; but the different salts possess different degress of solubility,[*] requiring more or less of this fluid for their solution.

What is meant by the FUSIBILITY *of a salt?*

Salts have not only the property of dissolving in water, but will melt by exposure to great heat. The different salts require different degrees of heat to put them in a state of fusion.

Have the different salts any action upon each other?

Yes: we have many instances of salts mutually decomposing each other.

What takes place in these decompositions?

When such salts are mixed in solution, the acid of the *first* and the base of the *second* having more affinity for each other than for the base and acid with which they are respectively combined, double decomposition, as it is termed, ensues. The acid of the first unites with the base of the second, and consequently the base of the first combines with the acid of the second; so that two new salts are produced, differing in appearance, and possessing properties different from those of the original salts.

What is the cause of this effect?

It is occasioned by mutual chemical attraction, and the operation itself is called double decomposition, or the effect of compound affinities.

Can you give an example of this double decomposition?

Yes: If you add a transparent solution of sulphate of soda, or Glauber's salt, to one of muriate of lime, the solution is immediately rendered turbid, and two new salts are formed. The sulphuric acid of the sulphate of soda combines with the lime of the muriate of lime and forms sulphate of lime or gypsum, and the soda which was combined with the sulphuric acid seizes the muriatic acid previously united to the lime and forms muriate of soda, or common salt, which continues in the solution, but may be obtained in a dry form by evaporation and crystallization. The white powder which precipitates, is the newly formed sulphate of lime.

What other use is made of these decompositions?

By these means many valuable salts are procured for the use of the chemist and the manufacturer, which can be formed in no other way.

What knowledge have we attained respecting the native *salts?*

Many of the salts are found native; and since the science of mineralogy has been so much cultivated, great attention has been paid to these natural productions.

What salts are furnished by nature in the greatest abundance?

The carbonates, the sulphates, and the muriates are most abundant; but some of the nitrates, borates, &c. are also found native.

Which of the carbonates have been found native?

Of carbonate of lime[†] there are immense mountains in most parts of the world: carbonate of barytes has been found in Lancashire and elsewhere; carbonate of strontites, at Strontian in Scotland; carbonate of soda in the natron beds of Egypt, in the East Indies; and carbonate of potash, as well as the carbonate of soda, has been discovered in some spring waters.

What sulphuric salts are found native?

Sulphate of soda is found in some salt springs; sulphate of magnesia, in spring water;[‡] the sulphate of alumina is abundant at Whitby and Glasgow; sulphate of barytes, in Derbyshire and other parts of the world; the sulphate of strontites abounds in some parts of Gloucestershire; and few salts are more copiously disseminated than the sulphate of lime, particularly in the vicinity of Paris, and hence its name *Plaster of Paris*.

What native muriatic salts are there?

Muriate of lime occurs with rock-salt, and muriate of magnesia is found in abundance in sea-water; muriate of ammonia appears in the neighborhood of volcanos; and muriate of soda not only exists in immense quantities in the ocean, but vast mountains in different parts of the world are entirely formed of this salt.[§]

Which of the NITRIC *salts are found native?*

Nitrate of potash is collected in various parts of the globe; nitrate of magnesia sometimes occurs in combination with that salt; and nitrate of lime is found also in the same combination, and likewise in mineral springs: these are the only nitric salts that have been seen native in any large quantities.

Are any other of the salts found native?

Yes: vast rocks in Derbyshire and elsewhere are formed of fluate of lime; borate of soda is found in a crystallized state in the kingdom of Thibet; borate of magnesia at Luneburg in the kingdom of Hanover; and phosphate of lime, which is the basis of all animal bones, exist native in Hungary, and composes several entire mountains in Spain.

How do you imagine that these immense masses of salts have been formed by nature?

The huge mountains of salts we have been speaking of, and which occur in various parts of the earth, were probably formed in very remote ages, and by processes of which we can form no idea. It may indeed be supposed that these changes have been slow and gradual, for several of the native salts exhibit marks of regularity and beauty in their crystallization, which cannot be imitated by art.[*]

Have geologists attempted to account for the production of the immense quantities and varieties of salts found in different states in various parts of the earth?

The cause of this order of things can only be referred to the will of the Creator,[†] who has seen fit, in the composition of many of the mountainous parts of the globe, to prefer these compound substances to the more simple and inert earths.

[*] We generally denominate all salts as insoluble, which require for solution more than 1000 times their weight of water. An opinion may in some measure be formed of the *solubility* of a salt by its force. Those salts which have the most taste are generally the most soluble in water. Thus Epsom salt dissolves in its own weight of water at the common temperature of the atmosphere, and the solution continues perfectly fluid and transparent; while sulphate of lime requires 500 times its own weight of water to hold it in solution.

[†] Chalk, limestone, and marble, are all included in the term, carbonate of lime. The late experiments of Sir James Hall have thrown great light on the formation of these natural productions. See *Edinburgh Philosophical Transactions*, vol. iv.

Carbonate of lime is found also in a crystallized state, in a mineral called *calcareous spar*. It has never yet been crystallized by art. This process of Nature may require many ages to effect, for aught we know.

[‡] Sulphate of magnesia and sulphate of lime are both very common in our spring waters; the last salt and supercarbonate of lime are the chief causes of what we call *hard* waters, which are very unwholsome, and unfit for washing. When soap is used with these waters a double decomposition takes place; the sulphuric acid of the selenite unites with the alkali of the soap and forms sulphate of potash or sulphate of soda, which remains in solution; while the magnesia or lime unites with the tallow, and forms an insoluble compound which swims upon the surface of the water like curds. In this way hard waters require much more soap for any given purpose than rain water, or waters which do not contain these earthy salts. Such waters are also unfit for boiling any esculent vegetable; but they may be rendered soft by adding to them a very little carbonate of soda, or carbonate of potash, 24 hours previous to their use. By this addition a decomposition will be effected, and the carbonate of lime, a very insoluble salt, precipitated.

[§] The salt mines near Cracow in Poland, which have been worked ever since the middle of the thirteenth century, contain an immense store of muriate of soda. The excavations have been made with so much regularity and beauty, that these mines are visited by travellers as one of the greatest curiosities in the world. Eight hundred workmen are employed in them, who raise 168,000 quintals of salt annually. Through the enormous mass of salt, which presents to the eye no interruption in its saline texture, and at the depth of 450 feet, flows a stream of pure, fresh and transparent water, which is received in large wooden vessels, where the workmen and horses of these subterranean regions quench their thirst. As it was impossible that this spring could filter through the salt, Nature, who buries her master-pieces in the bowels of the deepest mountains, has placed in this monstrous mass a stratum of clay sufficiently thick to allow the stream of water, destined to refresh the workmen, to pass through it in such a manner as to be protected from the action of the salt, of which a very small quantity would injure its salubrity.

[*] In order to account for these productions of Nature, various *theories* of the world have been formed by philosophers in different periods. Some of these have had many supporters. Thus we have had the theories of Burnet, Woodward, Whiston, Buffon, Whitehurst, Laplace, and other noted geologist who have written on the subject since their time.

The theories which divide the opinions of the philosophers of the present day, are those of Hutton and Werner. The former supposes the agency of heat, and is called the Plutonian system; the latter, which attributes all the present appearances of the globe to the effect of water, is called the Nepturian system.

[†] We have abundant reason to believe that nothing is fortuitous, but that every thing upon this fair world of ours is the effect of design; for every thing around us bears evident marks of the skill and beneficence of its Omnipotent Author. Is it not then reasonable to infer, that the formation of the whole of the globe entered into the divine plan; and that the constitution of the interior of its mountains resulted from the determination of infinite wisdom, and must have important uses in some future period of the world?—

> "For, lives the man whose universal eye
> Hath swept at once the unbounded scheme of things;
> Mark'd their dependence so; and firm accord,
> As with unfaltering accent to conclude
> That this availeth naught?"

It is probable indeed, that the profusion of earthy and alkaline salts which occur in the more elevated parts of the earth may, among other purposes, have been intended as magazines for the future renovation of the soils in their vicinities. They are in general of a nature to be washed down by the rains; and, by means of rivers, &c. are sometimes transported to considerable distances from their native beds. It is remarkable that these salts are generally found only in the *secondary* mountains, the materials of the *primitive* rocks being entirely different. These latter contain no remains of organic bodies whatever, and are composed, for the most part, only of five ingredients, viz: silica, alumina, lime, magnesia, and iron; of which *silica* is by far the most abundant, and universal. Though a comparative softness has been given to the secondary mountains, which thus appear to have been designed for the successive production of alluvial depositions, for the renovation of soils, &c.—the rocks of granite, the foundations of the globe, are so extremely hard, that it is imagined they would resist the constant wash of the ocean for ages without any apparent diminution. Where they were originally fixed by the hand of Nature—

> "They still remain,
> Amid the flux of many thousand years,
> That oft has swept the toiling race of men
> And all their labor'd monuments away." THOMSON.

In this arrangement we perceive nothing like a fortuitous concourse of atoms, but, on the contrary, the same satisfactory marks of contrivance, which force themselves upon our notice whenever we contemplate the various phænomena of the world, or study any of the great operations of nature.

Wealth.—Wealth in this country may be traced back to industry and frugality: the paths which lead to it are open to all; and such is the joint operation of the law and the customs of society, that the wheel of fortune is in constant revolution, and the poor of one generation furnishes the rich of the next.

In business, the keeping close to the matter procureth dispatch; and true dispatch is a rich thing.

Without frugality, none can be rich—and with it few would be poor.

Daily value of Sunshine.—The editor of the Genesee Farmer rates the agricultural products of the United States at *five hundred millions of dollars annually*, the perfection of which depends on the weather of four months, June, July, August and September. Without *sunshine* the crops would be a failure, either totally or partially, and hence we may estimate its average value at *four millions of dollars daily*.

ALBANY NURSERY.—This establishment now offers perhaps the best collection of Pears now in the country; [sec the June number of the Cultivator.] Also, Apples, Peaches, Plums, Ornamental Trees, Green-House Plants, &c. &c. A catalogue will soon be printed, and forwarded to order. Address J. BUEL & Co. post-paid. tf

FOR SALE—The subscriber wishing to close up his business, offers for sale the valuable Iron and Lumber Establishment, formerly owned and occupied by Penfield & Taft, situated on Putts creek, six miles from Lake Champlain, in Crown Point, Essex co. N. Y. The premises in question consist of a valuable water power, with a fall of more than 100 feet within sixty rods; on which there is now in operation a Grist-Mill with three run of stones, propelled by an overshot wheel; two Saw-Mills, one with overshot wheel and double gear, all nearly new and in good order; a Forge with two fires; and a machine shop for pounding and separating ore. The water for propelling these works is held in reserve by four ponds or reservoirs on the premises; the upper one being about 2½ miles in length, forming an ample reservoir for the whole works below, and affording sufficient water in itself for driving a forge with four fires and a rolling mill.

Adjoining the works are **600** acres of land, one-fourth of which is under good cultivation; on which are five dwelling-houses, convenient barns and out-houses, a store, blacksmith shop, and buildings convenient for other purposes.

There is also **1,000** acres of fine timbered land lying two or three miles from the above described works. Also, about five miles distant are **800** acres fine timbered land, on which are two Saw-Mills, and one of the richest, most extensive and valuable beds of iron ore yet found in the U. States.

Also, **1,900** acres of land in the towns of Schroon and West Moriah, Essex co. the greater part of which is covered with pine timber; 100 acres of which is under good culture, and on which is a good saw-mill, blacksmith shop, several dwelling-houses, barns and out-houses.

Also, one-half of a farm of 130 acres, situate on Lake Champlain, near the mouth of Putts creek, 2-3ds of it under good improvement; on which there is a large and convenient wharf.

On examining the above described premises, they will be found to combine unparalleled advantages for prosecuting an extensive business in the manufacture of lumber and iron, and for the sale of ore.

Such parts or parcels of the premises as are necessary for prosecuting the manufacture of iron and the sale of ore, will be disposed of separately from, or in connexion with, the lumbering establishment, as may suit the purchaser.

For the terms of sale, and all further particulars, inquire of the subscriber on the premises. ALLEN PENFIELD.

FOR SALE—A Splendid Country Seat in the Highlands, on the Hudson River. That beautiful country residence, known by the name of the BEVERLY ESTATE, containing four hundred acres of land, about two hundred of which are fine level arable soil, of an excellent quality, in a good state of cultivation, and not surpassed by any on the river for fertility; the remainder is fine and thrifty timber land. The situation is the most eligible on the Hudson, extending one mile and a half on the river, with a bold shore and convenient dock, nearly opposite West-Point, and within fifty miles of New-York. The prospect is extensive and diversified, reaching from St. Anthony's Peak on the south, to the bay and city of Newburgh on the north. This estate can conveniently be divided into three farms, giving an equal proportion of front on the river, and of arable and timber land to each. Almost every enclosure is supplied with living springs of the purest water. There is on said estate a plain house, (formerly the head-quarters of Gen. Arnold;) also out-houses necessary to carry on the business of the farm. The single fact that during the whole time the cholera raged throughout the state, not one case occurred within ten miles of this place, is sufficient to prove the unrivalled salubrity of the situation. The facilities of intercourse with the city, that can be reached in four hours, by means of numerous steam-boats, are great, and daily increasing, both as regards pleasure, and the convenience of a near market for produce of every description.

For conditions of sale, apply to STEPHEN A. HALSEY, 189 Water-street, New-York, or RICHARD D. ARDEN, on the adjoining farm. Ardenia, 23d April, 1839. j6t

MULBERRY TREES.—A few thousand Mulberry Trees are for sale at the Albany Nursery. They consist of the Multicaulis, Brussa, Chinese, that is, the product of Chinese seed, and the common white. The prices will depend upon size and quality. The Brussa is more hardy than the common, and the Chinese about as hardy; and the three kinds are believed to be equal, if not superior, to the Multicaulis, for silk; though it is proper to add, none of the mulberries that we have tried are propagated with so much facility, from buds and cuttings, as the multicaulis. The prices will be conformed to the average market price. tf

NOTICE.—The second Fair of the Onondaga and Cortland Association, will be held at Tully, on the first Wednesday of October next, for the exhibition of all kinds of Stock and Mechanics' products. All who feel interested are invited to attend. Tully, August 15, 1839.

Sept–1t. H. A. CHASE, *Sec'y.*

SOUTH-DOWN SHEEP.—The subscriber will sell the following Sheep, delivered at Albany, if applied for soon, viz:

					Price
1	full bred South-Down Buck,	(imported,)		3 years old,	$80
1	do	do	do	1 year old,	40
6	do	do	do	Lambs,	30

10 do South and Hampshire Down Ewes, (some of which were imported by Mr. Hawes, in 1833,) very old, price from $20 to $25. Eight Ewes from 1 to 2 years old, half South Down and half Bakewell, price $10.

All letters, postage paid, will be punctually attended to.
CALEB N. BEMENT, Three Hills Farm, Albany.

TO THE SILK GROWERS OF THE UNITED STATES.—In consequence of the difficulty of purchasing cocoons in the present state of the silk culture in this country, (competent agents for the purchase, at a distance, are not at present to be had,) and as the reeling of the cocoons is the foundation of the whole business in a national point of view, the subscriber is induced to receive cocoons from all parts of the country, to be reeled on shares, in the Italian style, for exportation; the silk to be returned to the owner, or the market price in cash, as may be desired. Persons sending cocoons for reeling, will please name for what purpose it is intended, whether for *Sewing Silk*, which requires 20 to 25 cocoons (or fibres to the thread,) or the finer qualities for weaving, say from 6 to 10, inclusive, and the product will necessarily vary with the *quality* of the cocoons. Worms poorly fed will produce light thin cocoons, and many of them so light that they will fill with water and sink, and consequently be lost. Cultivators will therefore see the importance of producing good cocoons—the largest are not always the best. The cocoons should be firm and hard to the touch. A large spongy cocoon will not yield much silk.

The terms for reeling for the present season, will be 20 per cent of the silk produced from each parcel of cocoons, which as they will be necessarily received in small parcels, will be attended with more trouble and expense than in after years, when the feeding of silk worms will be as extensively followed as is now the growing of cotton.

SAMUEL WHITMARSH.

Northampton, Mass. July 8, 1839.

N. B. The cocoons should be thoroughly *seasoned* before packing; they should not be *damp*, as they will *heat* in transportation. All bad cocoons in which the worms have died, should be rejected. They may be packed in flour barrels or boxes, with *holes* bored in the top and bottom, to give air, or in bags within crates, or in any way to prevent crushing them. They should not be crowded, but shaken into the barrels with the floss on. They may be shipped from any part of the U. States, direct to Hartford or New-Haven, Conn. whence they will be received by the canal or river boats, directed to "*Samuel Whitmarsh*, Northampton, Mass." sept–2t.

IMPORTED CATTLE—BERKSHIRE PIGS.—The subscriber intending to return to England, offers for sale his stock of Imported Durham Short Horned Cattle and Berkshire Pigs, at his residence, English neighborhood, Bergen county New-Jersey, five miles from New-York. The stock consists of 15 head of milking cows, 1 two-year old heifer, 4 one-year old heifers, and from 8 to 10 spring calves. Four of the above cows are imported, and the remainder are got by the imported Herd-Book Bulls Dishley, Durham, Wye-Comet, Hall's Comet, Memnon, Admiral, Denton, &c.

BERKSHIRE PIGS.—Ten breeding Sows, in pig and with pigs by them at the present time; from 40 to 50 Pigs ready for delivery at any time, at prices from $10 to $20 per pair, delivered in New-York.

The imported Herd-Book bred bull Bloomsbury is with the Cows for the season, and from present appearance will soon all be in calf. The yearlings and spring calves are all by my bull Snow-Ball, late Minevis, by Wye-Comet, dam Nelle, bred by Israel Munson, Esq. of Boston, got by the imported bull Admiral; grand-dam Rosa, bred by Mr. Munson, by the imported bull Denton, owned by Stephen Williams, of Northborough, Mass.: great-grand-dam Tuberose, bred by Mr. Wetherall, and imported by Mr. Munson.

For further particulars, see Herd-Book; Dishley, page 63; Durham, page 567; Wye-Comet, page 200; Admiral, page 2; Denton, page 43; Tuberose, page 524.

BENJAMIN BRENTNALL, English neighborhood,
sept–3t. Bergen co. N. J. 5 miles from N. Y.

BERKSHIRE PIGS.—The subscribers are ready to receive orders for their fall litters of Berkshire Pigs.—Several of their sows will come in from the 25th of August to the 5th of September. Orders for the south can be sent to New-York every day in the week, (Sundays excepted,) and reshipped by a faithful person, without charge, except for freight to, or cartage in, New-York. Orders or letters of inquiry, *post-paid*, will receive immediate attention.

sept–2t. H. & J. CARPENTER, Norwich, Con.

IMPROVED DURHAM SHORT-HORNS.—Mr. WHITAKER'S third sale of high bred improved Short-Horns, by the ship Napier, will be held at Powelton, near Philadelphia, on Friday Sept. 20, 1839, at 10 o'clock A. M.

The subscriber is authorised by Col. Powell to say, that all the best cattle which he has at any time imported, and the improved short-horns which he considered the best in England, were either in Mr. Whitaker's possession, or were derived from his fold. Col. Powell has not the slightest interest in Mr. Whitaker's sales. Philadelphia, July 15, 1839.

ts C. J. WOOLBERT, *Auctioneer.*

ALBANY SEED STORE, GARDEN and AGRICULTURAL SEEDS, IMPLEMENTS, TOOLS, &c. kept constantly for sale at his Seed Store, 317 North Market-street, wholesale and retail, consisting of a large assortment. It is the intention of the proprietor to test all seeds of which there is any doubt respecting their vitality, by sowing a few seeds in a small pot, before offering them for sale. And purchasers can test for themselves, any seeds of which they are distrustful, by sowing a few in a box of fine earth, and placing it in a warm room, exposed to the sun, where, if kept moist, the seed, if good, will vegetate in a reasonable time. In all cases where seeds prove to be bad, they will be replaced by others, or any reasonable satisfaction made. The proprietor has enlarged his establishment and increased his supplies, and with his experience in the business, together with his facilities for obtaining supplies, through Mr. GEORGE C. THORBURN, and his extensive correspondence and facilities for obtaining seeds, he flatters himself he will be able fully to meet the wishes and expectations of the public, and make the *ALBANY SEED STORE and AGRICULTURAL REPOSITORY* worthy of the high character it has already attained.

Persons ordering Seeds and Implements from a distance, with whom I am unacquainted, without remitting payment, are expected to give references in this city or New-York.

Sept–tf WILLIAM THORBURN.

GREAT SALE of IMPROVED SHORT-HORN CATTLE AND BLOOD HORSES.—The subscribers will sell at auction, on *Tuesday the* 10*th day of September next*, at the farm of Samuel Allen, on the Niagara river, two miles below Black-Rock, the entire stock of Imported Short-Horn Cattle, for several years past bred on the farm of L. F. Allen, on Grand-Island.

The herd consists of about thirty, including Cows, Bulls, Heifers and Calves. Several of them have been imported by one of the subscribers, direct from England, and with their produce, are surpassed by few animals in the country. In addition to these, every animal offered is the direct descendant of thorough bred imported stock, and of unquestionable purity of blood.

With the above will be sold twenty select and beautiful animals, consisting of pure Devon; crosses of different degrees between the Devon and Improved Short-Horns; crosses of the Alderney and Ayreshire with the Short-Horns. These are Cows, Heifers and Calves, all superior animals.

ALSO—The superb horse "BELLFOUNDER," got by imported Bellfounder, the best thorough-bred trotting horse ever in America, and out of the imported mare Lady Allport, bred by T. T. Kissam, Esq. of Long-Island. The stock of this horse is unsurpassed in the country for size, speed and action—together with several elegant, thorough-bred breeding mares and fillies, and two or three young horse colts, the produce of the above. These animals are of the highest character as roadsters, and as trotters, no blood in the country has excelled them. They are all from the best stables of Long-Island. Also, a beautiful pair of full-bred matched fillies, five years old. All these horses are blood bay.

This entire stock will be sold without reserve, to the highest bidder, commencing at 10 o'clock A. M. They can be shipped within an hour from the farm, on board the steamboats to go up the Lakes, or on board canal boats at the farm.

Catalogues of the animals, with descriptions and pedigrees, will be prepared, and the stock may be viewed at the farm previous to the sale. A credit of sixty days will be given on approved notes or acceptances, payable at a bank either in Buffalo, Albany, or New-York, for all sums over $300.

SAMUEL ALLEN. LEWIS F. ALLEN.
Black-Rock, N. Y. June 25, 1839.

FOR SALE—TWO SOUTH-DOWN BUCK LAMBS.—The subscriber imported, in the fall of 1837, two ewes and a buck, selected from the Earl of Leicesters flock, (Holkham,) of which the above is the progeny. Near Dobb's Ferry, Pa. July 28, 1839.

Sept–tf JAMES A. HAMILTON.

NEW-YORK URATE AND POUDRETTE COMPANY, not incorporated, but carried on by individual enterprise. The manures are not divided among the stockholders, as are those belonging to another establishment, but sold to applicants for cash on delivery. Orders are supplied in the order of time in which they are received. Urate 50 cents and Poudrette 40 cents per bushel, with contingent charges for bags or barrels, &c.

The company are daily preparing for use, during the warm dry weather, the materials collected during the past winter, and will have several thousand bushels ready before the first of October next. The material is disinfected and rendered free from offensive smell by a compound, every part of which is in itself a good manure. The experience of the past and present year, 1838 and 1839, on Long Island, has satisfied many of the farmers that these manures have the quickest operation upon vegetable matter, producing greater abundance, and the cheapest of any manure they have ever tried.

Amended instructions for their use, the result of practical experience, will be furnished on application. The effect of Poudrette upon grape vines and morus multicaulis is beyond all comparison. This company are erecting large and extensive works in the vicinity of the city of New-York to prepare the manures; and farmers and gardeners may confidently rely on a supply. Orders, post paid, directed to "The New-York Urate and Poudrette Company," box number 1,211, post-office, New-York, or sent to the store of STILLWELL & DEY, number 365, Fulton-street, Brooklyn, will be attended to. *New-York, July* 17, 1839.

The company will be very much obliged to gentlemen who have used the manures, to give them a statement in writing what has been the result of their use and experiments in relation to them. aug–4t.

FROM THE STEAM PRESS OF
PACKARD, VAN BENTHUYSEN & Co.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. OCTOBER 1839. No. 9.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—Lewis Hill & Co. Richmond, Va.; Bell & Entwistle, Alexandria, D. C.; Gideon B. Smith, Baltimore, Md.; Judah Dobson, bookseller, D. Landreith, and M. S. Powell, seedsmen, Philadelphia; Israel Post, bookseller, 88 Bowery, Alex. Smith, seedsman, P. Wakeman, office of the American Institute, Broadway, New-York; Hovey & Co. Merchants' Row, Boston; Alex. Walsh, Lansingburgh, and Wm. Thorburn, Albany, gratuitous agents; John Thorburn, seedsman and general agent, St. Louis, Mo. E. Valentine, Johnson's Springs, Va. See No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

☞ The engagements of the Conductor rendering it necessary that he should be absent during the first part of October, the next number of the Cultivator will be published on the first of November, and not on the 15th October, as heretofore proposed.

The Crops

Are represented to be unusually abundant throughout our whole land, with some partial exceptions; and the probability is, that we shall have a large surplus of all the productions of agriculture. Prices will therefore ultimately depend upon the extent of a foreign demand. Wheat is already selling in the western states at 62½ to 75 cents per bushel, and the expectation is entertained that prices will fall. This, as we have remarked, will depend on the foreign demand. While, therefore, we would recommend to the farmer, to sell at a fair remunerating price, we would not advise him to be frightened into a low price, by the representations of interested speculators. And as it requires more fortitude, or philosophy, to combat prosperity, than it does adversity, we advise the farmer to remember the fable of the milk-maid, who counted her chickens before they were hatched—not to run in debt on the strength of his abundant crops, till he realizes the amount of his actual sales.

There are, as we have observed, some drawbacks. Wheat has been seriously injured by rust, in many districts, particularly late sown spring wheat, many fields have not paid for harvesting, and other fields have not been harvested. We sowed some handsome varieties of foreign seed wheat, about the 15th May, and sowed our Italian at the same time, and in the same field.—The latter was somewhat injured by rust, while the new foreign varieties were virtually destroyed by it.

Indian corn, in some places, suffered by frost in August, and in many other places, and more severely, by the frosts of the middle of September. As the season has been much later than usual, it is feared this crop will prove very deficient, and defective in quality.

Hints for the Season.

"Like produces like," is an accredited maxim among farmers. Hence he who wishes to rear fine animals, should take care to secure good breeders, and he that would raise fine grain and roots, should take care to save, or procure, good seed, in time. This is the season to attend to these matters, particularly in regard to seed corn. If it has not already been done, no time should be lost in selecting the earliest and finest ears of corn, twin ears if you please, of stripping off most of the husks, of braiding, or wristing them, and hanging them in an airy loft to dry. Seed corn should never be suffered to go into a pile with the main crop, as it may heat, or mould, and lose its germinating principle. If the corn has been cut up and stooked, the early ripened ears may be readily distinguished, when the crop is gathered, by the colour of the husks and brightness of the grain.

The admonition which we give extends alike to other farm, and to garden seeds; and in regard to the latter, it may be remarked, that they keep better in their capsules, or seed vessels, than otherwise, provided they are kept dry.

Steeping seed wheat, and other small grains, in pickle, serves two, if not three good purposes. 1. The light and imperfect grains will float, and may be skimmed off. 2. It will prevent the crop being smutty; and 3. It will insure a more prompt and even germination. And if the seed is afterwards limed, before it is sown, as it should be, it will tend to preserve it from the attacks of insects. As a covering of one inch is thought sufficient for seeds that have been acclimated, covering with the harrow is deemed better than covering with the plough. "The wheat produced after the land has been limed, is believed to be thinner skinned, and to yield more good meal, than other wheat, and to make better bread."

To secure the best kinds of seed, of garden products, the most healthy plants must be chosen, and those which are most early in respect to the season; these should be so insulated, as to have no weak plants of the same species, or even genus, in their vicinity, lest the fecundating dust of weaker plants should be blown by the winds upon the stigma of the stronger, and thus produce a less vigorous progeny.

To collect good seeds, consists not in procuring new seeds from distant places, as is generally supposed, but in selecting the best seeds and roots of your own. This rule was practised successfully by the late Joseph Cooper, of N. J. who thus continued to propagate from his own seed for many years, with manifest advantage. We, however, think there are exceptions to the rule, in the potato and other crops where it is difficult, if not impossible, to make the required selection. In saving his radish seed, Mr. Cooper took ten or twelve that he most approved of, and planted them at least one hundred yards from others that blossomed at the same time. In the same manner he treated all his other plants, varying the circumstances according to their nature.

Seeds retain their vegetating principle for a greater or less length of time, according to the manner of their being kept, and according to their structure and properties. Thin seeds, as the carrot, parsnip, lettuce, &c. cannot be depended on after they are a year old. Peas and English beans will germinate well, it is said, at seven years old, while our common garden bean will seldom do well after the first year. Cucumbers, melons, squashes and pumpkins, are said to improve to the fifth, sixth and seventh year—the older the seeds are, the less the plants run to vine, and the more to fruit. Seeds have been made to vegetate and grow which have been one hundred years old, by the use of oxygenated muriatic acid and water.

To preserve seeds they should be kept dry, and kept alike from great heat and great cold. To transport them with safety a great distance, and especially to or from a tropical climate, the practice has been successful of mixing them with brown sugar, or with charcoal dust, or with raisins, in a close vessel.

All seeds should be sown when the soil is just ploughed or dug, as by these operations much atmospheric air is buried, which is essential to the germinating process; and the ground is withal moist, another requisite to quick growth.

The Pageantry of Republics.

To maintain republican principles and a republican government, it is necessary that we preserve republican habits and customs. We affect to hate kings, yet we worship men. We affect to be free, yet we glory in being the slaves of party. We profess toleration, yet we proscribe, as unworthy of public confidence, the brother who dissents from our political creed, or who refuses to support our candidate, be he ever so bad.—We are republicans by profession, but aristocrats or sycophants in practice.

Our news journals, for the last two months, have been filled with accounts of pageant processions, laudatory addresses, and sumptuous entertainments, got up, ostensibly, in honor of distinguished citizens, whose duties or pleasures have induced them to travel abroad. Thousands, many thousands, have been expended, a vast deal of time has been wasted, and some of the more dangerous of the human passions invoked, in getting up these shows,—not so much, we suspect, with the view of doing real honor to the individuals, as of strengthening the interests of party, and subserving the sinister purposes of individuals. As republicans, we ridicule the adulatory homage paid to the crowned heads and privileged classes of Europe, by what we term an ignorant and enslaved population; and yet we outstrip them in indiscriminate and fulsome panegyric, and partizan worship. Our constitution and laws regard public officers as public servants, not elevated for their own, but for the public good; yet, in our practice, we treat them as our masters, and it would be no wonder, such is human propensity to abuse power, if they soon assumed to be such. Rome granted triumphs to her distinguished men; and these distinguished men became her masters. Elections by the legitimate authorities soon ceased to be voluntary; and Cæsars were raised up, by the tumultuous acclamations of the mob, or the army, to curse and enslave the republic.

We would by no means withhold, from public officers, the respect due to their stations, nor from distinguished individuals, the honor due to their merits. We would as cordially tender our hand, and our respects, to merit, as any man, yet we verily think, that this respect and this honor would be more compatible with our republican professions, less derogatory to our dignity as freemen, and equally complimentary to those whom we would honor, if processions, cavalcades and military parade were dispensed with. It is but too apparent, that these pageants are got up for party, and not for public benefit; and that if tolerated, they will increase in frequency and in mischief. It is not the evils that have happened that we so much deprecate, but the evils that are likely to grow out of these anti-republican precedents. It should be a man's virtues, his public services, and his fidelity to our republican institutions, that should recommend him to public confidence and support—and these are likely to be known whenever they are developed—and not the number of partisans which can be drummed up to swell his cavalcade. A good man needs not these extraneous anti-republican contrivances, and a bad man is certainly not entitled to them.

We intend no political or personal allusions in these remarks. We consider the practice a bad one, inconsistent with our republican professions, one that is growing upon us, and one that should be discountenanced by the sober, reflecting part of the community.

Schools of Agriculture.

When we consider that agriculture is the great business of the nation—of mankind;—that its successful prosecution depends upon a knowledge, in the cultivators of the soil, of the principles of natural science—and that *our* agriculture stands in special need of this auxiliary aid—we cannot withhold our surprise and regret, that we have not long since established professional schools, in which our youth, or such of them as are designed to manage this branch of national labor, might be taught, simultaneously, the principles and practice of their future business of life, and on which, more than on any other branch of business, the fortunes of our country, moral, political and national, essentially depend. We require an initiatory study of years, in the principles of law and medicine, before we permit the pupil to practise in these professions. We require a like preliminary study in our military and naval schools, in the science of war and of navigation, ere the student is deemed qualified to command. And yet, in agriculture, by which, by the permission of Providence, we virtually "live, and move, and have our being," and which truly embraces a wider range of useful science, than either law, medicine, war or navigation, we have no schools, we give no instruction, we bestow no governmental patronage. Scientific knowledge is deemed indispensable in many minor employments of life; but in this great business, in which its influence would be most potent and useful, we consider it, judging from our practice, of less consequence than the fictions of the novelist. We regard mind as the efficient power in most other pursuits; while we forget, that in agriculture, it is the Archimedean lever, which, though it does not *move* a world, tends to *fill* one with plenty, with moral health and human happiness. Can it excite surprise, that under these circumstances of gross neglect, agriculture should have become among us, in popular estimation, a clownish and ignoble employment?

In the absence of professional agricultural schools, could we not do much to enlighten and to raise the character of American husbandry, by making its principles a branch of study in our district schools? This knowledge would seldom come amiss, and it would often prove a ready help, under misfortune, to those who should fail in other business. What man is there, who may not expect, at some time of life, to profit directly, by a knowledge of these principles? Who does not hope to become the owner, or cultivator, of a garden or a farm? And what man, enjoying the blessing of health, would be at a loss for the means of an honest livelihood, whose mind had been early imbued with the philosophy of rural culture—and who would rather work than beg.

An early acquaintance with natural science, is calculated to beget a taste for rural life, and rural labors, as sources of pleasure, profit and honor; to stimulate to the improvement of the mind—to elevate and to purify it—to self-respect, to moral deportment. And it will tend to deter from the formation of bad habits, which steal upon the ignorant and the idle unawares, and which consign thousands of promising young men to poverty and disgrace, if not to premature graves. A knowledge of these principles, to a very useful extent, can be acquired with as much facility, in the school or upon the farm, as other branches of learning. Why, then, shall they not be taught? Why shall we withhold from our agricultural population, that knowledge which is so indispensable to their profit, to their independence, and to their correct bearing as freemen?—Why, while we boast of our superior privileges, keep in comparative ignorance of the principles of their business, that class of our citizens who are truly the conservators of our freedom? We know of but one objection—the want of teachers. A few years ago, civil engineers were not to be found among us. The demand for them created a supply. We have demonstrated, that we have the materials for civil engineers, and that we can work them up. We have materials for teachers of agricultural science, which we can also work up. Demand will always insure a supply.

The Conversion of Manure into Crops.

The great business of the farmer, who aims at profit, should be, to convert *useless* into *useful* matter—*dead, putrid* organic matter, into grain, grass and roots—into meat, milk and wool—into farm profits—into the means of wealth and rational happiness. To facilitate this desirable process, we bespeak the careful attention of the reader to the two articles, inserted in this and our last numbers, entitled "Agricultural Chemistry," written by Henry Madden, and copied from the Edinburgh Quarterly Journal of Agriculture. The part published in September, relates to *organic matters*, the true food of plants, and the true sources of agricultural profit and wealth. The part published to-day, relates to the mechanical and chemical improvement of soils, by means of mineral productions, or other than organic matters. Taken together, they form an excellent treatise and guide for the profitable management of the farm. And we beg of the unlearned reader, who may be disposed to throw them aside, unread, on the plea that they smack too much of science, carefully to preserve them, until himself, or his sons, shall wish, as they assuredly will, to consult them. Depend upon it, they contain much of deep interest, to him who would profit by the improvements of the age, as regards the profits and pleasures of agricultural pursuits.

And yet we cannot endorse all of Mr. Madden's principles, without some explanatory remarks. He urges a partial fermentation of vegeto-animal manures, or in other words, of stable and yard dung, before it is buried in the soil, on the ground, that crops stand in immediate need of its fertilizing powers, which can only be developed after fermentation has commenced; and we infer, that his remarks apply to small grain crops.—Scotland, for the benefit of whose husbandry Mr. Madden writes, is in a high latitude, the average heat of summer there being probably from five to ten degrees less than with us, and where the Indian corn crop, one of our great staples, is never attempted to be raised.—The decomposition, or fermentation of manure, is therefore more tardy there, when buried in the soil, than it is with us, and may not, consequently, take place in time to meet the wants of the early sown small grains. But with us the case is different. We have a hotter summer, to bring on earlier and more thorough fermentation in the soil. Besides, our unfermented manure is, or ought to be, principally applied to a crop which Scotland cannot grow—to our Indian corn, which needs its greatest stimulus after the small grain has been harvested. Unfermented manure applied to the corn and potato crops, to which it ought mainly to be applied with us, if spread broadcast and buried superficially in the soil, will decompose in time for the wants of these crops, if the soil is, as it should be, in a healthful condition, and will continue to afford them food, at a time most needed, when they are maturing their grain and their tubers in autumn, better than manure which has previously undergone the process of fermentation. When unfermented manure is deposited in the hill, a practice which we deprecate, these advantages may not result to the corn and potato crops. The manure, from lack of moisture, may not ferment, and of course will remain inert, if it is not prejudicial. We consider the corn and potato crops admirably calculated, in this way, to secure to us all the virtues of manure, without any preliminary process of fermenting it in the yard.

Seedling Plums.

There is no part of the Union, we believe, where so many fine seedling plums have been produced, as in Albany and its neighborhood. Plums have ever been a favorite fruit here, and the climate and soil seem well adapted to bring them to a fine state of perfection, and there has for many years been amateurs who have cultivated the best kinds with care. Where none but good kinds are cultivated, seedlings coming from them can scarcely be otherwise than good, proceeding as they must, from none but good parents. Among those who have thus produced esteemed varieties, to begin with olden time, we may name Mrs. Bleecker, Peter Yates, Chancellor Lansing, Isaac Dennison, Col. Young of Saratoga, Mr. Judson of Rensselaer, and some gentlemen in Schenectady. Many of these fruits bear the names of those who first introduced them into notice. There are probably fifty fine varieties which have been thus originated, superior to many named in the nursery catalogues, many of them remaining without any distinctive name. We tasted of nearly twenty new kinds last year, in Mr. Dennison's garden, all of high flavor; and we have just received a box of samples of seedling fruits from Col. Young, also of superior quality. We have also a seedling in our grounds which we esteem as highly as any we grow. As the season is now too late to do it, we throw out the suggestion, that the growers of new kinds, in this city and neighboring towns, meet together at a suitable time next year, with samples, to give them names, and to decide on their relative merits.

Frost.—In some of the northern districts, a severe frost was experienced early in September. Where corn is yet standing, we advise that it be immediately cut up and put in stook. We *know* this mode of harvesting will save the grain, and increase the fodder.

An Official Opinion.

"A post-master may enclose money in a letter to a publisher of a newspaper, to pay the subscription of a third person, and frank the letter, if written by himself."—AMOS KENDALL.—*American Farmer.*

Many post-masters have been scrupulous of enclosing moneys to printers of newspapers, from third persons, under an honest impression, that they would contravene the spirit of the post-office law. These doubts will now be dissipated by the above decision of the Post-master General.

The legitimate object of the post-office department, is not to accumulate revenue, but to accommodate the public, by as cheap and expeditious transmission of letters, newspapers and pamphlets, as the receipts of the department will allow. The construction here given by the Post-master General, will rather increase than diminish the revenue, because it will multiply the newspapers transmitted by mail. A post-master who desires, or is willing, to promote the diffusion of useful knowledge, may receive from a dozen or more of his agricultural neighbors, their subscription moneys for an agricultural journal, and transmit it free of charge to the publisher. The individuals will be benefitted, and the community will be benefitted, by the spread of useful knowledge, and the post-master will have the satisfaction of reflecting, that he has been instrumental in bringing about this good. Whereas, were each of his neighbors obliged to pay double postage on his letter and enclosure to the printer, often 50 cents, he might be deterred from becoming a subscriber, and himself and the public would lose the benefit of the improvements which the paper might induce.

Agriculture among the Romans.

Agriculture, among the Romans, was the *great* business. The first men studied its principles, directed its operations, and wrote treatises for the instruction of the unlearned. Some of the writings of Cato, Varro, Virgil, Columella, Pliny and Palladius have reached the present age. They show a familiar acquaintance with all the details of farming. The wealthy citizens, who spent their winters in the city, and their summers at their villas in the country, personally superintended every department of their business "Though the operations of agriculture," says the author of ancient husbandry, "were generally performed by servants, yet the great men among the Romans continued to give particular attention to it, studied its improvement, and were very careful and exact, in the management of all their country affairs." "After the landlord," says Cato, "has come to the villa, and performed his devotions, he ought that very day, if possible, to go through his farm; if not that day, at least the next. When he has considered in what manner his fields should be cultivated, what work should be done, and what not; next day he ought to call the bailiff, and inquire what of the work is done, and what remains; whether the laboring is far enough advanced for the season, and whether the things that remain might have been finished, and what is done about the wine, corn and all other things. When he has made himself acquainted with all of these, he ought to take an account of the workmen and working days. On holidays, old ditches may have been scoured, a highway repaired, briers cut, the garden digged, the meadows cleaned from weeds, twigs bound up, thorns pulled, far (bread-corn, maize,) pounded, all things made clean. When he is fully satisfied in all these things, and has given orders for the work that is to be finished, he should inspect the bailiff's accounts; his accounts of money, corn, fodder, wine and oil; what has been sold, what exacted, what remains, what of this has been sold, whether there is good security for what is owing. He should inspect the things that remain, buy what is wanting for the year, and let out what is necessary to be employed in this manner. He should give orders concerning the works he would have executed, and leave his orders in writing. He should inspect his flocks, make a sale, sell the superfluous wine, oil and corn; if they are giving a proper price, sell the old oxen, the refuse of the cattle and sheep, wool, hides, the old carts, old iron tools, &c. Whatever is superfluous he ought to sell. A farmer should be a seller, not a buyer."

And Columella directs the proprietor, on returning to his farm in the spring, "to view his marches, inspect every part of his farm, and observe whether in his absence any part of discipline or watchfulness has been dispensed with; and whether any vine, any tree, or any fruits are missing. Then, likewise, he ought to review the cattle and servants, all the instruments of husbandry and household furniture. If he continues to do all these things for some years, he will find a habit of discipline established when he is old; and at no age will he be so much impaired with years, as to be despised by his servants."

These directions are valuable, even in our day, to landed proprietors, particularly in the south, whose farms or plantations are managed by overseers or agents. There is great truth in the saying of Poor Richard, that a man who would thrive by the plough, must himself either hold or drive.

Northeast Storms.

Franklin, we believe, was the first to notice publicly, that northeast storms began at the southwest. During the last four days of August, the clouds portended rain with us, and the winds and temperature indicated a northeast storm upon the Atlantic coast. Yet we had not a drop of rain, and September brought us a clear sky and milder weather. It appears from the Norfolk papers, that a northeast storm commenced there on Wednesday the 28th, that the gale was severe, and much rain fell; and that the storm continued to rage with much violence during Thursday and Thursday night. On Friday the gale reached Boston. The wind blew with great violence, and the rain fell in great abundance. On Saturday it passed the barrier of the Green Mountains, in the form of a moderate rain, and continued in Dutchess, Orange, &c. from midday to midnight. The storm was probably felt earlier at the southwest, and later at the northeast.

Morus Multicaulis.

To keep our readers advised of the price current of this staple commodity, we state, on newspaper authority, that extensive sales have been made in Virginia, at 1½ and 2 cents the bud; that in the vicinity of Hartford, most of the plants have been bought up at 30 and 35 cents the plant; and that on Long-Island, prices have gone up to fifty cents a tree. A *tree* is supposed to be the growth of a bud planted last spring. Those who have to sell, we advise to take the above prices, if they can find buyers; but those who wish to buy will suffer no loss, we apprehend, in delaying to purchase at the above prices. Ten cents is a profitable return for each bud planted.

Effect of Slaking Lime.

"The *weight* of lime is increased from *thirty* to *fifty per cent* by slaking; and its *bulk* is *tripled* or *quadrupled.*"—*See Prof. Jackson's remarks on limestone.*

These are important facts to the lime burner and lime buyer. To the burner, as it shows that the expense of transporting his lime to market, is a quarter less, in its fresh burnt state, than it is when the lime is slaked.—Nor should it be forgotten, that a ton of fresh burnt lime will acquire in five or six days, by exposure to the atmosphere alone, an additional weight of four or five hundred pounds. To the buyer, these facts teach the importance of buying fresh burnt lime. If he buys by weight, according to the Albany standard, lime long exposed to atmospheric influence, or imperfectly burnt, he pays for a quarter more than he gets. If he buys slaked lime by measure, he gets in the bushel only one-half, or one-third, what the bushel would give him in the fresh burnt-stone.

THE BUDGET.

Locust Hedges.—"I would like to know how honey locust hedges answer, when they become old, or if there is any thing better for hedges?—*Horace Wells.*" We have never seen an *old* honey locust hedge; yet judging from the appearance of our own, eight years old, we should think they will answer well, provided they are properly grown, and are kept properly clipped. Mr. Wells will find our opinion as to the best material for hedges, and of the mode of growing them, at pages 126, 176 and 192, of volume iv. of the Cultivator.

Peat Earth.—C. B. Clark has addressed to us several queries in regard to the value of peat as a manure, which it is wholly out of our power to answer satisfactorily, without knowing the quality of the material, the distance to which it is to be transported, and nature of the soil which it is to benefit. Peat is generally vegetable matter, which, on being brought into a state of decomposition by contact with fermenting materials, affords the proper food for farm crops—enriches lands. It may be worth much to those who have it at hand, and it may not pay expense to those who have to transport it a distance. These are matters of calculation which every farmer must make for himself, and for which no general rules can be prescribed. If we wish to fatten animals for the butcher, it is prudent to know beforehand, what the fattening materials will cost us, and what they will be worth to us—whether we are likely to lose or gain by the process. If there is no prospect of gain, we will sell the lean animal to him who has greater facilities for fattening. As with our animals, so it is with our crops. Manures constitute their food. Like animals, they should have good attendance; and if by an outlay of $5 in manure, we can add $10 to the value of their product, we realize a nett profit of $5. If we can apply this to a farm of 100 acres, it results, that an expenditure of $500 for manure will give a nett profit of $500—a result not at all uncommon, and very often below the actual gain. We can merely say to Mr. Clark, that every animal and vegetable substance is convertible into the food of plants; that it costs no more to cultivate a rich acre, than it does a poor one, and that hence, as a general rule, it is best to be liberal in our expenditures to make our land rich, that they may be productive and profitable.

Hog-Pen.—We have received from Long-Island a diagram of a hog-pen, which we doubt not is useful; but with all ingenuousness we are obliged to acknowledge, that we do not understand it; and believing that our readers will not, we must forego the expense of a cut till it is put into a more intelligible form.

Plans of Houses.—We received from Mr. Jewett and from Mr. Smealle, each two plans of houses. They were all placed in the hands of the gentlemen selected to award the premium. But in arranging them for publication, some mistakes have been made, and we don't know but we have given the diagrams of what each considered the least perfect. But verily we are unable, at present, to put the matter right.

Planting Trees.—"Being about to set out trees for ornament around my dwelling, I would be obliged to you to say, through the Cultivator, whether it will answer, in our region, to set them out in the fall of the year, and at what time in the fall would be best?—*A Franklin County Subscriber.*

Answer.—Deciduous trees, that is, trees which shed their leaves in autumn, may be transplanted with safety, when they are not in a growing state, that is, at any time after the functions of the leaves have been arrested by frost in autumn, and before they come into leaf in the spring. If planted in autumn, in a high northern latitude, it is well to throw around the tree a shovel full of dung, or stable litter, to protect the roots from the cold of winter, and this may be withdrawn in May. *Evergreens* are best transplanted when they are growing, say from the 20th May to the 20th September—and we think the earlier in this time the better. Litter may also be thrown about these with advantage, not as a guard against frost, but to prevent evaporation.

Shovel Plough.—Solomon Rathbun, of Verona, Oneida, asks where he can obtain them, adapted to a two-horse team? As we cannot inform him, will some reader, who has them for sale, answer Mr. R's question, by writing him?

Disease in Calves.—Richard Shaw, of Berlin, Rensselaer, writes us, that his calves, 24 in number, about a fortnight since, were seized with a cough, of which several have died, and the rest, as well as a large stock of cattle, he is apprehensive of losing.

Grape Culture.—A Litchfield subscriber asks sundry questions in regard to the culture of the Isabella grape. He will find most of the information he desires in Mr. Tomlinson's communication in to-day's paper, and in Mr. Spooner's, vol. v. p. 61. The Isabella likes a rich and a moist soil. The cuttings are best made in autumn, and may be kept in the cellar, or buried in the soil.

Tomatoes.—In answer to the same correspondent, who asks how the tomato should be managed, and whether it will bear engrafting on the potato, we state, in the first place, that nothing, not even water or other liquid, is required to *cook* this vegetable. It is merely peeled, whan ripe, of its outer coat, and placed in a sauce pan over the fire, where it will cook. As to *seasoning*, tastes vary. Some put in merely salt, some salt and pepper, some add to these a little raw onion, and this is the way we like them—some add sugar, crum of bread, &c. In the second place, the tomato probably might be grafted on the potato, they belonging to the genus *solanum*. Our correspondent can easily make the experiment; but we confess we do not perceive that any benefit will accrue if he succeeds. We suspect the grafting of annuals will be found rather *curious* than *useful*.

Acknowledgements.

Four baskets superior New-Jersey peaches, from Dr. McChesney and J. Pullen, Hightstown, N. J. and from Robert White, jr. of Shrewsbury. A superior made patent pail, from M. Pond, proprietor of the extensive pail manufactury at Schuylerville.

CORRESPONDENCE.

A National Agricultural Society—A National Agricultural Convention proposed.

ESPECIALLY ADDRESSED TO THE EDITORS OF AGRICULTURAL JOURNALS, AND TO AGRICULTURAL SOCIETIES.

Essex County, Va. August 29, 1839.

DEAR SIR—Only a few days before I received your paper of the 15th of this month, I had read an account, in one of our political journals, of the last meeting of the "English Agricultural Society," at which our distingushed countrymen Mr. Webster gave them a speech. This account elicited in me so ardent a desire for the establishment of a similar society in the United States, that I was on the point of addressing *you*, and through your paper, the editors of all our other agricultural journals, a most earnest request to unite heart and hand in an effort to bring it about. But, to my great gratification, I find, by the last Cultivator, that you have anticipated me, by suggesting the project in your brief remarks upon the meeting of the English society. Do, my good sir, urge it again and again, upon all your subscribers, as well as upon your brother editors. It can hardly be possible, I think, that so agricultural a people as we are, should have so little of the spirit which should actuate us all, as not to be effectually roused into action when properly addressed; and who so fit to apply the necessary stimuli, as the editors of papers devoted to this great national cause?

Can we, the people of the United States, who boast of being more enlightened than any other civilized nation, in regard to all those principles and arts of government which are best calculated to promote and preserve human happiness—can *we* be so immeasurably behind them all, in applying these principles, and cultivating these arts, as not yet to perceive, that legislative aid to agriculture, in a country like ours, is a vital element in our national prosperity? It is, in fact, to the Body Politic, what the heart's blood is to the Body Natural: neither can exist in health and vigor, without its appropriate aliment.

What are the obstacles—the rational objections to aiding this vital art by legislation? Shall we be told by some of our martinet politicians, that our Federal Constitution forbids? Would to heaven they had been as lynx-eyed in guarding it against *other* attempts to infringe it—if indeed, the establishment of a National Society of Agriculture would thus operate! That the nation would have been richer by millions than it now is, could we have had such an institution, can not, I think, be doubted for a moment by any who are at all aware of the vast benefits which have resulted both to England and France, from the encouragement given by each to husbandry in all its branches; and I have yet to learn any good reason why we should not follow their example.

But thanks be to our good constitution, it has a provision in it which is perfectly intelligible, even to the most stupid; and none can dispute about the powers which it confers. I mean that which relates to the mode of choosing our immediate representatives. *This is the king-cure-all* for every political evil, provided it be executed as it *may* and *should be.* For example, let the agricultural districts—of which there is a vast majority in the United States—choose none but honest, intelligent and zealous agricultural men, or staunch friends to the cause, to represent them, and they might rely, with absolute certainty, that this cause would no longer suffer from the want of any aid that could be legitimately bestowed on it. Such members of congress would very soon find out a way to form a National Agricultural Society, that would speedily become one of the most popular associations in our whole country; and would prove in a few, a very few years, the means of extending to the utmost extremities of our Union, such a mass of information in regard to all the various branches of husbandry, as could not fail to render our nation the richest, as it is still, I believe, the happiest on the face of the earth. Our commerce and manufactures, which, next to agriculture, are the great sources of national wealth and power, would soon be abundantly supplied with all the materials essential to their prosperity; and nothing would be wanting to consummate our happiness, but the moral and religious education of our whole people.

Can there possibly be a single individual within the limits of our vast confederacy, who doubts this, even for a moment? *If there is*, I can only pray heartily, that he may speedily see the error of his ways, and most cordially co-operate in the attempt to establish a National Agricultural Society, with all of our fraternity who have full faith in that admirable proverb, (applicable, by the way, to all imaginable associations,) which tells us—"*United we stand—divided we fall.*"

One word more on this subject, and I will rely upon other and abler advocates to support it. Since it has become the fashion of late years to hold conventions for almost every purpose in which many persons are interested, I would respectfully propose, that one be held *in the City of Washington, on the second Monday of December next*, with a view of forming a National Agricultural Society; and that the different societies for the promotion of agriculture, throughout the United States, be invited to send deputies to it. Where no such associations exist, county meetings might be held of the friends of the cause, who might depute one of their own body, or the member of congress from their respective districts, to represent them in the convention. Should you approve this scheme, your paper might commence the invitations, and solicit your brother editors to repeat them. In this way, the proposal would speedily reach every state in the Union, and would first fall into the hands of the best friends to agriculture in each, for *they* alone deserve the title who support our agricultural papers.

Anxiously hoping that you will see this matter in the same light that I do, I remain, dear sir, your friend and constant reader. J. M. G.

Rust on the Potato.

Post-Office, Westmoreland, Oneida co.
N. Y. Sept. 16, 1839.

DEAR SIR—As I am a farmer on a small scale, permit me to inquire of you, if the potato crop is often, or ever, in any section of country, cut short by its being struck with rust in a similar manner and about the same time that wheat is?

I have about two acres, and on digging a part of them, I find it takes thirty hills to get a bushel. This induced me to inquire of larger farmers in this town, the prospect of their potato crop. The universal expression is "very light crop." Among the many I have conversed with, one or two by observation, think it is owing to its being struck with rust; a new idea to me, perhaps it is familiar to you. How is it?

Yours obediently,
ABRAHAM HALLECK.

REMARKS.—We have heard of the *curl* destroying the potato crop, in Great-Britain, but have not before heard of its being injured by rust. The remark has, however, been made to us, that *this* year, the tops die prematurely, from what cause is not stated, and that the crop, where it has been taken up, proves unexpectedly to be a short one.—*Conductor.*

Propagation of the Grape.

Hon. J. BUEL—Dear Sir—I sent you a dissertation on trees, and omitted to say something on grape vines, as I intended.

In transplanting grape vines with roots, I have found it difficult to save them. They have many very fine roots, and if they are not put up in wet moss, or some other wet preservative, they soon perish.

There is no difficulty in raising grape vines from good slips, much less than with roots. Cut the slips in autumn, after the leaves have fallen, and the vine has hibernated for the winter. Choose round and sound wood, well ripened and firm, (no flat wood,) the buds full and plump, the joints short between the buds.—(Suckers from the root of the vine, with long joints, are worthless.) Cut the upper end off within half an inch of the bud—put them in the ground sloping, the lower end deep, to have moisture. The upper bud should be covered half an inch under the ground, to break off the sun, and they are as easy raised as currant slips. I have set many slips with the upper bud above ground, as advised. They grew at first well, but the sun invariably killed them before the fall.

I planted some slips this season, and they have already grown from two to four feet. I have had bunches of grapes the third year on slips thus planted. If they are planted in sunny places, they should be watered the first year. Water is always acceptable to grape vines of any age. If not put out in the autumn, then cover the slips with wet ground or mulch, and set them in the spring. If put up in damp moss, or other matter, to prevent the slips from drying, they may be taken to Europe or elsewhere, till from November to May. Respectfully, D. TOMLINSON.

Remarks on Breeding.

Stockport, 9 mo. 10th, 1839.

ESTEEMED FRIEND, J. BUEL—"Walker on intermarriage," is the title of a work just republished in this country. Its object is to point out the rules to be observed in the selection of wives, with a view to the production of a beautiful, healthy and intellectual offspring. Although the primary object of the author is to ameliorate the form and intellect of the human species, by means of judicious intermarriages, yet he treats largely on the means of improving inferior animals, by means of breeding, and asserts that all his newly discovered laws, relative to the human species, are equally applicable to domestic animals. It is to the views which he takes of this latter subject, that I wish to call the attention of my agricultural brethren. Although I do not think he has *demonstrated* the laws, yet he has certainly brought forward a very respectable body of proof, for their support, sufficient at least to induce those who are interested in obtaining good animals, to give their serious and careful attention to his views.

It is necessary to observe, in order to render the sequel intelligible, that by the "locomotive system," we mean the organs of support, of motion, and of connexion, or bones, ligaments and muscles; and by the "vital system," we mean the organs of absorption, circulation, and secretion. The organs of absorption are sometimes denominated lacteals or lymphatics; their use is to absorb the nutritious portions of the food from the intestines, and to convey it to the heart, where it is mingled with the blood. The organs of circulation are the blood vessels, which circulate the blood from the heart to the extremities, and from the extremities back to the heart. The organs of secretion are the glands, where the various fluids of the body are secreted. The foundation of Walker's system of breeding is, that "like produces like." This has been stated before, but never satisfactorily shown to be the case, or in other words, while other authors have stated this to be the rule, they have at the same time stated such a numerous list of exceptions, that we are left in doubt whether it is any rule after all. These exceptions are shewn by Walker to be only apparent and not real.

The second law is extremely important if true, (and in order to ascertain whether it is so or not, nothing more is necessary than for one farmer in every county in the state, should observe it for two or three years, and send the result to the Cultivator office.) "Organization is propagated by halves," that is, one parent communicates to the offspring the fore part of the head, the long part of the face, the forms of the organs of sense, and the whole of the internal nutritive system. The resemblance to the parent who thus communicates "the vital system," will therefore be found in the forehead and long parts of the face, as the orbits, cheek bones, jaws, chin and teeth, as well as the shape of the organs of sense, and the tone of the voice. The other parent communicates the posterior part of the head, the bones, ligaments and muscles, or the whole of the fleshy parts. The resemblance to the parent who thus communicates the "locomotive system," must be found in the back head, the few more moveable parts of the face, as the external ear, under lip, lower part of the nose, eye-brows, and the external forms of the body, in so far as they depend on the muscles, as well as the form of the limbs, even to the fingers and toes, &c. If this law be correct, viz. that "organization is propagated in halves," or that one parent gives the *whole* of the "vital or nutritive system," and the other the whole of the "locomotive system," it will be perceived that many of our commonly received opinions and practices are erroneous. In crossing, we are commonly directed in the selection of a male to choose one most perfect in the points where the female is most deficient. But from this law, we learn that we shall not in all cases, accomplish our object. If a part of the "vital system" in the female is deficient, and we seek to improve the progeny by crossing with a male, perfect in these particulars, yet defective in some other portion of vital system, we shall fail, because one parent must necessarily communicate the *whole* of the vital system, as the other must necessarily communicate the *whole* locomotive system.

But I shall tresspass too much on the columns of the Cultivator, by tracing out the practical inferences. I shall therefore confine myself to a bare statement of the laws themselves. If we inquire how we are to ascertain in what cases the male will give the locomotive system, and in what cases he will give the vital system, we are told by Walker, that where both parents are of the *same variety*, it is impossible to predict which series of organs will be communicated by the male, as between a bull and cow, both of the Short-Horns, or both of the Herefords. But in cases where the parents are of different breeds, as a Berkshire sow and China boar, both parents being of equal age and vigor, the male gives the back head with the locomotive organs, and the female the face and nutritive or vital organs. In individuals of the same *family*, that is, in breeding in and in, as between mother and son, or brother and sister, precisely the reverse takes place, the male then gives the face and vital organs, and the female the back head with the locomotive organs.

I have thus briefly stated some of the more important laws of breeding, discovered by Walker. Of course, in the narrow limits of a communication, it is impossible either to give the facts from which the laws were deduced, or the important practical consequences resulting from them. These latter, however, will readily suggest themselves to intelligent breeders. What I have written is offered with a view to guide them in observing the laws of procreation and, in the hope that if these laws are found to correspond with their experience, they may be induced to communicate their observations for the columns of the Cultivator.

N. N. D.

5,512 Product from one Seed.

Wheatland, Aug. 29, 1839.

Mr. J. Buel—Sir—I wish to inform you and the public, through your paper, the Cultivator, the great amount of wheat grown from one kernel of the common bearded wheat, grown in this town, which is 106 stalks, averaging 52 kernels to a stalk, amounting to 5,512 kernels.—

ALLEN SAGE.

Plans of Farm Buildings.

Jesse Buel—Respected Friend—On looking over the Cultivator of August 15th, I saw a number of well arranged and convenient plans of Dwelling Houses, which reminded me of one I drew and had published in the Farmer and Gardener, in the year 1835, accompanied by a plan of a barn also; I herewith send the wood cuts of both: if found worthy of a place in thy paper, thee may publish them. Having lately built nearly such a dwelling on my nursery farm, except one wing, which is omitted for the present, which on a year's trial, I find to make a very comfortable summer and winter house, by opening or shutting the folding doors between the two parlors. My spring being near the east end of the wing, and the ground falling in that direction, admitted of a wash-house under the kitchen, with its out door on a level with the ground. In this I have a large bake oven and boiler. This house is built in a neat, permanent manner, of stone, hewed granite to the water table in front and imitation granite above, with granite sills and portico floor, marble chimney pieces, pilaster casings, 8-4 doors and slate roof; cost here, where most stone are high, $4,101, exclusive of gates, gravel walks and ornamental planting, &c. I also built a barn some years ago, on this plan, except corn cribs, which were omitted, of stone. Cost $1,200, exclusive of gathering stone on the farm and hauling them, sand and lumber, with the farm hands. Respectfully,

ROBERT SINCLAIR, Sen.
Clairmont Nursery, near Baltimore, Md.

To the Patrons of the Cultivator.

Having in early life learned drawing and architecture, and being for several years engaged in the construction of buildings, I have derived great advantages, subsequently, from the information thus acquired, in the erection of even the roughest building on my farm, enabling me as it did in its plan and arrangement, to consult economy and convenience, and to adapt it to the peculiar purposes for which it was required, with the least possible expense, matters which, with a judicious agriculturist, should never be lost sight of. Indeed, according to my views, these are the chief objects to be consulted in the whole internal economy and management of a landed estate, whether regard be had to its cultivation, or to the improvements thereon. In saying this in favor of what may be considered the *useful*, I wish it not to be thought that I would reject, or that I am not a lover of, appropriate architectural decorations and ornaments; for of these I am a warm and decided admirer, and especially so where the means are ample, and can be spared from such things as are essential to comfort.

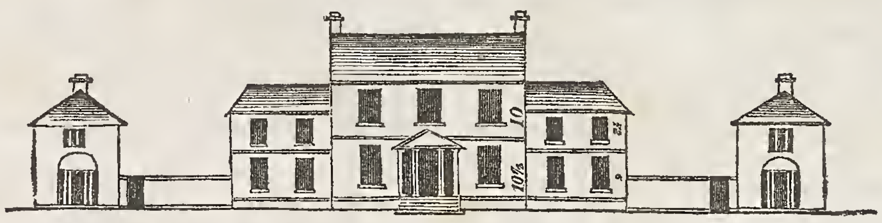
The approach to this building is intended to be either from the east, west, or north, and to terminate at the north door; to be protected from the northern blast by tall oak, hickory, or such other trees as may be native there, thinly scattered over the ground, which may be set in grass; and these to be interspersed with groups of *balsam fir*, or other evergreens, tastefully arranged for effect. Should such protection not be practicable, a well cultivated orchard of fruit trees will answer in their stead; but the latter, as well as a good vegetable garden, would, probably, except in the case described, answer best, if placed eastwardly of the mansion, and the farm buildings, such as barn, stabling, &c. to the westward, or reversed as might be required by the site, leaving the south front an *open lawn*, unincumbered with trees, except here and there, at a distance, single ornamental trees, with a few clumps of evergreens, and on the right and left small groves of ornamental trees and shrubs, so arranged as to make the lawn in front widen as these groves extend from the mansion.

Explanations of the Drawings.—*Of the Mansion.*

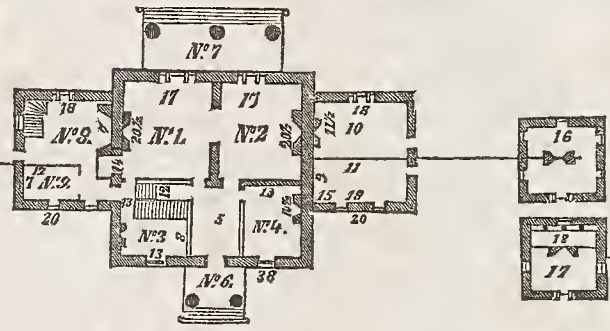
A. Plan of the first story.

B. Elevation of the north front, with study and manager's house to the right and left.

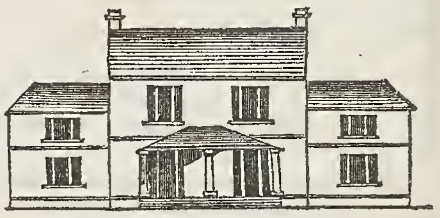
[Fig. No. 37.]—Plan B.



[Fig. No. 36.]—Plan A.



[Nig. No. 38.]—Plan C.



C. The south front.

No. 1, common parlor: No. 2, drawing room: No. 3, housekeeper's or dressing room: No. 4, breakfast room: No. 5, entrance hall: No. 6, north portico: No. 7, south portico: No. 8, kitchen: No. 9, pantry: No. 10 & 11, office and store room or working shop, &c.: No. 12, passage from hall to kitchen, under the upper flight of stair steps, (this might if necessary be converted into a pantry or closet for china:) No. 13, passage from common parlor to dressing room.

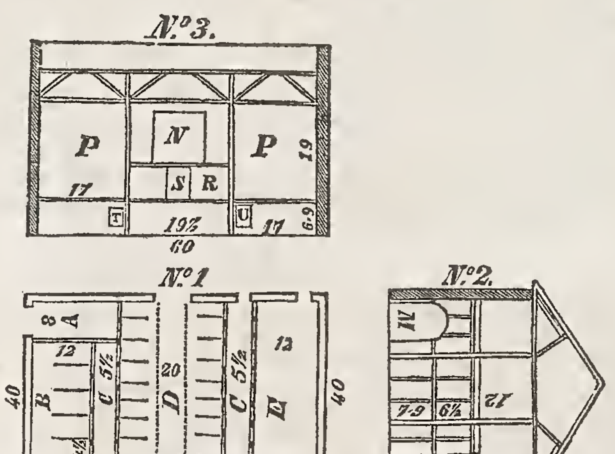
The second story to be divided as below with the addition of one room over the hall. The *garret* will make four good rooms, by having two windows in each gable end, and two dormant windows on each front.

By the arrangement of the rooms on the first floor it will be perceived, that, from the common parlor, with three steps the mistress of the family can be at the cellar door, which is situated under the first flight of stairs, or at the dressing room door, as occasion may require, and that with five steps she can reach the kitchen fire, a most important place, by the bye, for her to keep a vigilant eye over, if she be desirous of having her culinary affairs judiciously managed or her cooking well and economically done.

It will be observed that the kitchen fire place is in the rear of, and immediately adjoining, the back of the common parlor fire place. With some, this location of the kitchen fire place may be viewed as an objection, and as rendering the appearance of the building not as attractive as it would be if the chimney were at the extreme outer end of the kitchen, and with such I am ready to join in opinion. But if they only desire to relieve the general aspect of the building from what might be viewed in the light of an architectural deformity, their object can be attained by a very simple process, and one too, of but inconsiderable expense—by merely carrying up chimneys from the study and servant's rooms. Should this latter suggestion not be adopted, it will readily be conceded that the apparent defect in the beauty of the house is more than balanced by the superior utility, and increased comfort arising from the location of the kitchen fire place, as before premised. If the flue or funnel of the kitchen fire place be carried up in the same stack of chimneys, as those of the mansion house, being of the same height, it will be less liable to smoke than if under the influence of the eddy which would be formed were it carried up independently of, and of less elevation than, those of the main building, as they necessarily must be, if projected from the outer end of the kitchen. There are two other advantages to be gained by building the fire place adjoining the parlor: first, it will contribute largely towards warming it, and secondly, it will be more convenient for the superintendence of the mistress of the family, and yet the sitting parlor may be rendered entirely private, when necessary, by closing the door.

Having thus explained the drawings of the mansion house and its appendages, I shall now proceed to describe the *necessary* farm buildings for such an estate, and particularly if a large quantity of hay be raised and much stock be kept.

[Fig. No. 39.]



No. 1. Ground plan.
A. Carriage house.
B. Family horse stable.
C.C.C. Feeding passages.

D. Cow stables with door to back the cart in for the purpose of hauling out manure.

E. Stable for work horses.

F.F. Two lathed corn cribs.

G. A vacant space under the bridge leading into the barn, and between the barn and bridge abutment, which admits of a door into the granary between the stables and barn floor.

H. A walled embankment or bridge-way into the barn.

F.F. A covered enclosed way into the barn under which are two corn cribs, between which the cart passes into the barn.

M. A carriage-house door.

N. Barn door.

P.P. Hay mows.

R. A granary story divided into garners.

S. A door leading into the granary story.

T. A door to the feed passages.

U. A window with wide moveable slats to shut out cold, or let in air—several of these are necessary in the different stables.

V. Step ladder.

No. 1. A ground plan of a barn sixty feet by forty, showing the stalls and seats of the upright posts dividing and supporting the barn.

No. 2. A section of the gable end of the barn, showing all the timbers and scantling.

No. 3. The north section of the barn shewing the timbers and doors.

Inasmuch as the stone abutment of the bridgeway into the barn has to be built eight or nine feet from the back of the barn, to give entrance and air to the granary story, that part of the bridge has to be made of wood; hence the necessity of projecting the eve of the roof of the barn so as to protect the wood work from wet and consequent decay; and by boarding the outside and inside with a light frame of oaken lathe, one by three inches. two commodious corn cribs five by eleven or twelve feet will be formed, to throw corn into, in wet weather, as it may be husked in the barn. Under this bridgeway and these corn-cribs, there will be a convenient cart-shed, provided the barn be not built on too much of a declivity. From three to five feet is sufficient fall from the north end of the bridge-way to the south front of the barn, as the stabling is far more healthy when not much under ground. The earth may be removed from the foundation to the outer part of the bridge-way, so that the cost of it will be trifling, except for the wall around it to keep up the earth. By means of this bridge and covered-way, we not only gain a cart shod and two corn-cribs, but are enabled by it to get the carts, when loaded with either grain or hay, up into the barn floor, sixteen feet above the floor above the stables, thus affording the facility of conveying the hay and straw, by means of a funnel, to be prepared for the purpose, into the feed passages and granary below. The hay mows being seventeen by thirty-seven feet, and nineteen feet high, will hold a very large quantity, and besides a great deal may be stowed away above the square in the roof, there being no collar beams to take up the room. About one-half of these immense stowing rooms being below the caving rail, which is three and a half feet above the barn floor, the hay may be rolled off the cart into the mows, thus saving all the trouble and labor of pitching it up into the loft, as is the case in such stables and barns as have their floors on a level with the ground.

On the south front a cow-yard ought to be enclosed about one hundred and ten feet long, and from sixty to one hundred feet wide, according to the number of young cattle to be wintered in it. The milch and working cattle being fed in the stalls renders it unnecessary for it to be large. In this yard there ought to be either a fountain or pump to supply the stock with water. And it will be necessary for the horses to have a separate trough and apartment in the yard, and there should also be a shed along the east end for the cattle to go under in stormy weather.

It will be seen, that in this barn, all the provender necessary for the winter's supply, whether of hay, straw, or grain, can be stowed away; and that, from its great conveniences, all the stock may be fed during that period of the year, without those having charge of them being necessitated to go out of doors; and should the precaution be observed, of hanging up the gears of each horse, on hooks to be provided for that purpose, behind them, which should never be omitted; such as may be wanted may be harnessed without a moments's delay.

An implement-shed should, in addition to the buildings I have described, be erected near the stable, which beside its real utility in the preservation of tools and implements, always reflects credit upon the proprietor of an estate.

I think it will strike the intelligent farmer and planter, that by thus concentrating the out-buildings on an extensive plantation, convenience, economy and comfort, to man and beast, are all eminently consulted, and that in point of beauty in appearance, it very far surpasses the old *plan* if it may be so termed, of having a barn here, a stable there, corn-house in one place, and a cow-house in another—this latter arrangement always had in my view a most unslightly and un-system-like aspect.

If a thrashing machine should be intended to be used in the getting out of the grain, preparation for the horse-path may be made under barn floor, in the cow stables, or in a part of one of the passages, from which a strap may pass upwards to a wheel on the machine.

ROBERT SINCLAIR.

Importance of selecting Seed.

Liberty, Bedford Co. Va. August 22, 1839.

To Judge Buel, Editor of "The Cultivator."

Sir—It has been said that he who enables us to rear two blades of grass where formerly we raised but one, is a benefactor to mankind. He then who teaches his fellow men to rear two ears of corn where formerly they raised but one, is no less a benefactor of his species. Several gentlemen in our country apparently claim paternity of the idea of selecting seed corn from the most prolific stalks. And many purchase at high prices small parcels of seed corn thus selected, called after a Mr. Baden, whose name it has assumed from his distributing it, and from its singular yield, &c. It matters not to the cultivator who rears it, what name it bears, or who first conceived the idea, so he is benefited by it. Nor should its true parent care, so he can enjoy the high gratification of having promoted the interest of his fellow men. The idea was first suggested to me in the year of 1800, when a small boy, occasionally attending to my father's stock of animals, from the peculiar fruitfulness of a single one of them and all her progeny of both sexes, which I particularly noticed for several years; and in 1815, when I became a cultivator of the soil, my first object was good seed of every crop I wished to raise. And recollecting the success of my experiments in raising stock from the offspring of the above animal, I commenced the experiment on the vegetable creation, by selecting my seed corn (the most important crop in our country,) in the fall of 1815, exclusively from stalks having two good ears on them, cutting the stalks off at the ground, and hanging them in a high dry place secure from rats, &c. until planting season; then shelling off a little from the small end of each ear and planting the balance of the ear; and being fully satisfied of the increased product, disclosed it to my neighbors, all of whom, who saw my corn in the field, or who tried my seed with their own, were fully convinced of its beneficial results, and by degrees it has spread over the country generally. In the fall of 1821, as a means of diffusing the information as above acquired as extensively as I could, I wrote to Mr. Skinner, editor of that most invaluable periodical, "The American Farmer," of Baltimore, (and which paper I am pleased to hear Mr. Skinner has recommenced publishing in that city. Those having that paper of above date can refer to my letter.) Soon after which, I sent to several gentlemen, at their request, supplies of seed corn near Baltimore, Richmond, Charleston, &c. all of whom were fully satisfied on the first trial of its peculiar and uncommon product. Some years afterwards it was said by some that the crops from the seed collected as above was later, and of course more subject to injury from early frosts, &c. To obviate which, I selected my seed from the double, treble and quadruple ears that were most forward, and soonest matured and ripe. This was done without any sort of trouble, as follows: When my hands were cutting the tops off the corn in September, for winter forage. &c. I directed the tops to be left of those stalks *only* which had the most forward and fine of the double, treble and quaddruple ears, which was perceptible to every eye by the dead silks, or by the shuck whitening and drying first, &c. By this mode at gathering time one may know at a distance all the selected seed corn; and by this process, in a few years, my corn was decidedly earlier and more forward than any of the same kind, the seed of which had not been selected from the most forward, as was acknowledged by all who planted of my seed thus selected. I would, therefore, respectfully suggest, through the medium of your very valuable and widely circulating paper, "The Cultivator," to all corn planters (as well as of vegetables generally) of any kind of corn they choose to cultivate, not to reject the idea because their ancestors have not pursued it from time immemorial; and after a few years' trial of it, (which can give them very little trouble) if they should find no benefit from it, to drop it. I have not for many years, owing to professional duties, increased afflictions, and other causes, attended to this subject as much as its importance deserved, although it has not been wholly neglected; and I can now show in my fields of Indian corn, of the same identical kind I commenced with in 1815, many stalks having three, four and five ears each; and some (including short corn) six, seven and eight ears each. A brother chip of mine, in an adjoining county, some years ago, purchased a small tract of land and planted my seed corn on it the first year, and assured me the following fall, that the astonishing product from that seed had enabled him the same summer to sell the land at an advance of over one hundred per cent profit. I might relate many other facts of some interest on this subject, but my purpose will be fully answered, if from what I have said, I may induce those who cultivate the soil to try this experiment themselves, as well with other vegetables as with Indian corn; for I doubt not a fair experiment would prove equally propitious and satisfactory with many of the vegetable creation if fully and fairly tried. Indeed, the selection of good *ripe*, well chosen seed of any and every kind, is well worthy the attention of every cultivator of the soil. I may, Mr. Editor, towards planting season, give you some account of my experience as to the manner of preparing seed corn when planting, &c. and its results, (as this letter is already long enough,) and I hope editors of agricultural papers and newspapers will give the above suggestions an insertion for the benefit of their patrons, &c. Your subscriber, and ob't serv't,

WM. COOK.

To prevent the Murrain in Cattle.

East Raisinville, Monroe Co. Mich. July 26, 1839.

J. Buel, Esq.—Dear Sir—In the July number of the Cultivator for this year, which came to hand two or three days since, I have read the communication from Mr. Payn of Black Locust Grove. I have never read any thing which more fully accorded to my views and experience on the subject of murrain in cattle. For the last thirty years I have resided in the north part of the state of Ohio and in the east of Michigan. I have suffered severely in the loss of stock by this grievous plague, until about eight years since, losing every year more or less, from one to sixteen head in a season. As for a specific cure, I do not believe there is any; but I will give you the result of my experience as to a preventive. If you think best to give it to the public through the columns of the Cultivator, you are at liberty to do so. About eight years since I had lost two fine oxen, and was then doctoring the third, which was in the last stage of the disease. An elderly gentleman was passing, and rendered me some assistance. He told me that there was no use in doctoring; the better way was to prevent. He gave me the following as a preventive, and added that it was so simple he doubted much whether I would follow it. He said, fix you a trough in the yard where your cattle could go to it every day, and mix equal portions of slaked lime and salt, and keep it always there. "And," he added, "if after three months, you lose a creature, draw an order on me and I will pay for for it." Since that time I have literally lived up to the specification, and I have never lost but one cow since, and I have kept from fifteen to fifty head on my farm ever since. Now, sir, whether it is the addition of lime, or whether it is the regularity of always having salt where they can take what they please, and not one day take a larger supply than is heathful, and then be without, I do not know, but there are some facts I do know, that the stock will not consume as much salt mixed with lime as they will without; and such is my confidence in the remedy, that when I change my cattle to fresh pasture, that my portable salt trough goes with them, and is always kept well supplied with the mixture. I said I had lost one cow: the circumstance was this: on examining into the matter, I found the man that had the care of my stock (for I was much away myself) had put the lime barrel down cellar, and the moisture of the cellar had entirely destroyed the properties of the lime. My method is to procure my lime and set it in a dry place, and let it air slack, and I am always supplied with the article as fast as I need it. With this instance excepted, I have never seen a healthier stock than mine, and I attribute it entirely to the lime and salt, as there is in this country, and my neighbors all around me are losing more or less every season. I am not able to give you the whys and the wherefores about the matter, nor am I competent to write for the Cultivator; and I have to say, that should it be published it will require some time and patience to make it as it should be; but the correctness of the facts I vouch for. Yours with great respect,

LEANDER SACKETT.

Rev. Mr. Lodor's Select School.

Montvue, Warren Co. Va. (P. O. Middletown,
Fred. Co.) August 20th, 1839.

Honored Sir—In the Cultivator of the present month, (vol. VI. No. 6,) I observe an editorial notice of my private and select school. I certainly feel under obligations to you and your kind correspondent. The notice referred to, terms it *a manual labor school*. The labor, however, is altogether *agricultural* and *horticultural*. Formerly, a *mere manual labor* system was pursued, but the idea of an *agricultural* school was first obtained from the perusal of your truly valuable periodical, of which I have the pleasure to be a subscriber and constant reader. The plan of my school is, to enable youth to obtain literary and scientific, in connexion with agricultural knowledge, and at the same time to diminish the expenses of their education by their personal labor in the garden and on the farm. It is altogether a private establishment upon a small scale, no more being admitted to the agricultural department than may be deemed necessary to carry on a limited system of rural occupations. The course of education pursued in the literary department is a liberal one, yet the number of students likewise limited. In this department, I have the happiness to say, a number of young men have been educated, who stand high in the several professions of law, medicine and divinity. The agricultural department is as yet in its infancy, but as far as my experiments have extended, I see no ground for discouragement, although an entire novelty in this part of the country. I hope you will excuse the liberty I thus take of calling your attention to the error in terming it merely a *manual labor school;* an error of little importance in itself, were it not that it makes your periodical apparently depart from its legitimate objects in noticing that which has no immediate connexion with agriculture. The connecting of an agricultural department with my school, I do not consider of any pecuniary advantage to myself, the labor of inexperienced youth by no means compensating for the deduction required to be made in their session bills. Yet I cannot doubt the ultimate success and utility of these schools in a country like ours. And I hope you will persevere in your laudable efforts to press this subject upon the attention of the community. I have been much interested in reading your articles on this subject, both editoral and from correspondents. And may you reap the pleasure of beholding success following your every effort. The high encomiums passed upon your periodical by gentlemen of scientific and agricultural standing in every part of our nation, render any expressions on my part altogether superfluous. Suffice it to say, that it is considered by myself and friends here as decidedly the most useful and the most ably conducted agricultural publication within our knowledge. Very respectfully,

JOHN LODOR.

Common School Education.

Schenectady, 11th September, 1839.

Dear Sir,—In your last number of the Cultivator, for September, I saw a "Circular on Common School Education," over the signatures of the distinguished names of Theodore Frelinghuysen of New-Jersey, Charles Brooks of Massachusetts, Henry R. Schoolcraft of Michigan, Theodore Dwight, jr. of New-York.

It is a pleasing circumstance that such men have engaged in this important cause. I hope a new system of education will be established,—I mean a new set of books, written purposely, so that when children are learning to read, they may learn the principles of a moral life.

The best patrimony that children inherit, is a correct moral education. Hitherto children have been taught to read, with the single object of learning to read only, when they might have had the foundation of a moral life, if the books employed in teaching were so written as to inculcate those firm principles of moral ethics which are calculated to make us happy in this life, and the only mode of living so hereafter, by learning to love God with all the heart, and our neighbor as ourselves. If this divine principle was in full practice here, we should enjoy heaven on earth. And is it not chargeable to faulty education that it is not so?

Some persons assert, that the natural temper and faculties of man are the sole cause of their evil conduct in this life, and that it cannot be prevented by education. Such opinions must arise from want of observation. Why are the inhabitants of South Africa and Southern South America living in a degraded state, almost on a par with the brutes? And yet those men are made with rational faculties of improvement like all other men, where the greatest improvements have been made, by cultivating their natural faculties.

A friend of mine informed me, many years ago, that he knew a man of a family, living on the border of Oneida lake, in the state of New-York, at the time when that county was a wilderness. The son told my friend that they could not raise a pig without great care, as bears and other wild animals would take them for food. That they had a cow, which fed in the forest; that his mother went to look in the woods for her to milk her, and that if night overtook his mother before she found the cow, she made her bed, when the darkness stopped her search. This was a white woman, and it must be evident that her degraded state was chargeable to want of education. What a wide difference between that woman and a delicate and well educated woman, in civil society! And is not education the sole cause of difference?

Education does not always produce virtue, for education has not always been founded on virtuous principles. Even our accademic schools are faulty, in teaching the dead languages in books written by those who knew not christian principles, and exhibited the most glorious actions to be those which could accomplish the greatest destruction of their fellow men by skilful warfare. Even the teachers of morals are faulty. Paley has been the standard of moral ethics in our colleges, and Paley's maxims are almost void of christian moral ethics. They are mere worldly expedients. If such a course is pursued, when will our youth become moral and correct? Education makes the man and the christian. "Evil communications corrupt good manners." I pray that these distinguished men, when in convention in November, as proposed, will renovate the whole system. God bless their labors to that use.

While a convention of such men, and for such purpose, meet for the improvement of education, I would suggest the propriety of their giving attention to the correction of orthography. There is now a great waste of time and space in writing many words, according to the continuation of the old mode of spelling, such as spinning, beginning, running, &c. &c.

The verb of spin is changed to the participle of the present tense by adding *ing*, when ning is nonsense, as ning is a word of no meaning. So the verb to commit, is changed to the participle of the past tense, by adding *ed*, when the present mode is *ted*, which is nonsense. So the using two g's in the word drugist, bagage, wagon, &c. &c. I have, for a long time, made the correction, under the risk of being called a faulty speller.

It needs some authority to make the correction general. Lexicographers dare not, but such a convention would be justified, and receive public approbation and thanks.

Will you please to make this known to those gentlemen. It can't offend them. Respectfully,

DAVID TOMLINSON.

The Peach Tree Grub.

New-York, Sept. 17, 1839.

I desire to add my mite to the stock of information communicated by Mr. Lancaster in vol. 6, No. 8, of the Cultivator, at page 133, in relation to the grub worm.

There are two causes of decay in the peach tree:

First. Over bearing, by which the tree is exhausted, arising from the unwillingness we have generally to part with any of the fruit, and neglecting to furnish the proper food for the tree.

Second. The grub worm.

When I resided in New-Jersey, I took great care and spared no expense to have good peaches, and while I did that I had great abundance.

The course I pursued was, every spring and early in autumn to clear away the ground at the stem of the tree near the roots and near the surface of the ground, and put tobacco leaves round the body of the tree, then cover up the tobacco with the earth, the dampness of which round the tobacco caused an effluvia that no *worm* could penetrate the tobacco, or live in or near the root of the tree, if peradventure he had got in there. To prevent exhaustion I sent to the woods and procured the surface soil, which was decayed leaves, and is a valuable food for the tree.

This course I pursued several years, and while I did it I had every year a great abundance of the finest fruit, and as soon as I neglected it my trees failed and were destroyed by the grub. I have recently discovered what I think will be a complete protection against the grub, and a manure that will furnish food for the tree far better than any thing yet tried. I have not yet tried it to the peach tree, because now I have no peach trees. I have recommended others to try it, and hope to do it another year myself.

I would put around the roots of the peach tree, having first cleared away the earth from the roots, about 4 quarts of poudrette as manure, and draw the earth over the poudrette in the spring of the year. It has proved the most valuable manure for grape vines, morus multicaulis, and young apple trees, when they are first set out, of any other application whatsoever.—Next to, and around the body of the tree, and at the root, where the grub is sure to make his entry, I would *put two quarts of urate,* spring and autumn, and cover it over with the earth, and sprinkle it in a slight degree with water. *Urate* is similar to what hartshorn is sometimes made of, and when damp produces as strong an odor as the strongest hartshorn, and you may judge how long a human being could live inhaling at every breath the smell of hartshorn, and then you can easily imagine how long it is possible for a *worm* to live in it.

I have killed the grub by the application of boiling hot water, poured from a teakettle on the root and body of the tree where they were, and have seen the sickly leaves assume a healthy appearance for a time.

A. DEY.

Application of Salt to Trees—The Borer.

Whalen's Store, N. Y. Aug. 17, 1839.

J. Buel, Esq.—Dear Sir—A communication has been going the rounds in the papers, recommending the application of salt to the roots of fruit trees. I would say to those disposed to try it, do so cautiously; salt in large quantity will destroy all kinds of vegetation, even the Canada-thistle itself, and if the application be a liberal one, I will venture to say, it will kill every tree, root and branch, that it comes in contact with. Permit me here to state a single experiment I made three years since, to free the yellow-locust from the borer. I had some half a dozen trees in my door yard, about four inches in diameter, that were in a fair way of being soon destroyed by this pest. I cleaned out the holes from whence the dust issued, and pushed lightly into each with a stick, a small piece of camphor about the size of a large pea; from that day to this the borer has entirely ceased its operations on the trees thus served.

Respectfully yours, SETH WHALEN.

Physiology—Improved Husbandry—Agricultural College.

Hon. J. Buel—Dear Sir.—All vertebral animals circulate red blood, and all other animals below, and not vertebral, and all insects, have white blood. The blood of all animals is white at its formation, and from its passage from the absorbing vessels, which take up the nutriment and convey it through the lymphatic vessels to the blood in the large veins, from which it enters the right auricle of the heart, thence to the right ventricle, whence it is thrown by the heart into the lungs. There it is changed, with the dark colored venus blood, to the florid red color. It then is returned to the left auricle of the heart, thence to the left ventricle, whence it is thrown, with the power of a steam-engine, into the aorta which branch to the upper and lower region of the body, and the blood is circulated to every minute part of the body and skin, to nourish, invigorate and beautify the body. It then enters the capillary veins and is conveyed to the larger veins, till it reaches and passes the great vena porta through the liver, to the heart, to perform again the repeated circulation to nourish and sustain the body. Breathing air cannot be dispensed with for a few minutes only without the loss of life. The blood must be thus renovated and supplied with the principles of life, in the lungs, by the air, for new and constant nourishment of the body, or the heart will refuse to circulate it and sustain animal life, and the body must die.

Death is the absence of life. The moment the body ceases to live, the muscles become flaccid, and their full, round and beautiful appearance vanishes. The skin puts on her cadaverous habiliments, and decomposition of the body commences, and progresses rapidly if the weather be warm, and slower if cold. It is dissipated—earth to earth, dust to dust, water to water, air to air, &c. &c. So the various component parts of the body seek their native home in their homogenous elements. Many of them are taken up by the vegetable family, and become food for animals, forming new combinations, in vegetable and animal bodies, which die, and are again the sustenance of other vegetables and animals without limit.

It is astonishing that the pagan tradition of the resurrection of the *body of flesh,* it so strongly impressed on the mind in childhood, as to continue through life, when the common sense and truth of the fact is so plainly and forcibly illustrated by St. Paul to the Corinthians, (I Corinthians, 15 chap.) in combating the same error in that day, of the resurrection of the *body of flesh.* The body is dissolved and scattered to the four winds of heaven: and if it were to rise again and live, it must be subject to a second death—to be burnt alive at the great and final conflagration—for flesh and blood cannot inherit the kingdom of heaven, says Paul. The red blood of all animals is alike, and if viewed through a magnifying glass, there appears little if any difference in it; and that apparent difference, probably, is more speculative than real.

All animals that breathe air in a volume, have hot blood. The heat of the blood is derived from the air, which is suddenly decomposed on entering the cells of the lungs, and the latent caloric in the air is let loose, and enters the blood with the oxygen. This may be in some measure illustrated by slaking fresh burnt lime. If water is poured on stone lime, just enough to slake the lime suddenly and no more, the water is so suddenly absorbed by the lime as to become solid with the lime, leaving the caloric free, so that it may kindle and ignite wood and other combustibles.

All animals that do not breath the air, have cold blood. I would not be understood to say, that there are any animals that do not breathe air; for all animals, and all vegetables, every thing possessing life, breathes air in limited portions. Even the oyster breathes air. It finds sufficient air in the water, where it is bred, feeds and lives. The film or fringe around the edge of the shell, is the lungs which inhale air from the water. If the oyster is shut up close, to exclude water and air, it will soon perish, as all animals must.

So the foliage of vegetables are the lungs, and if air be excluded from them, they must perish. They must have light also; for without light a long time, the leaves die and fall off, and the plant stops its growth. House plants kept in a dark room or celler in winter, prove this. But some vegetables, like some animals, suffer sooner than others when deprived of air. The potatoe vine will drown almost as soon as many animals or insects will, when covered with water. If it is covered with water but a few hours, it lingers and perishes.

Some aquatic plant find sufficient air in the water, where they grow, to sustain them, as fish do, and perish if placed in the air, as they cannot inhale air in a volume. The fish are observed to be constantly swallowing water, which passes out at the gills, which are the lungs, and they inhale air from the water sufficient to sustain life.

The large whale must breathe a volume of air, and must throw himself out of the water to breathe. Although he rolls head and tail out of water to breathe, which he does apparently in an easy and leisurely manner, yet, when he is seen to rise again, the distance he has made, shows that he moves with the velocity of the steam-boat, as I have noticed them in pairs, in the Atlantic ocean. Their tail is flat, or horizontal, like the porpoise and herring hog, all which rise above the water to breathe air. The whale sails with the tail; and by bending it under water, and then extending the tail suddenly, can throw his huge body with great speed above the water to breathe.

The farmer may, if he will, by contemplating these natural properties and propensities of animals and vegetables, learn how to preserve both in health and growth. He may learn that good air is indispensable to all animals that live in the air. All animals of the farm stock are more healthy, and thrive better, if their places of feeding and sleeping are furnished with wholesome and fresh air. So the various plants cultivated on the farm require to be planted, some on the dry part of the farm, and others where the ground is more damp. Regular moisture suits potatoes. If their growth is suspended by drought for a while, and after the tubers are of some size and are again supplied by rain, they are apt to sprout again; certainly if the vines are dead; and when they do so, the potatoes are of inferior quality. Damp ground, where the water will not pond, is suitable.

The public are convinced that there has been a great defect in agricultural management; particularly in this state. Not many years past, the state of the harvest in Europe was anxiously inquired after, particularly England, whether there was a prospect of a market there for our surplus bread stuffs. It is now within the knowledge of all, and painfully by many, that, the population of the state of New-York has fed on European wheat, to the amount of many millions annually, for several years past; and that, too, when there was not a failure of the crops of wheat here. Pork and beef have also been scarce and prices high. These prove a faulty agricultural management.

Your Cultivator furnishes many statements of great crops—double and treble product on the acre, by scientific culture, above the ordinary and ignorant mode of farming.

It is notorious, that when the vegetable soil of the land in Dutchess county, in this state, had become exhausted by extensive culture, it was supposed that the land was of no value; and in some instances it was abandoned as not worth fencing for tillage. By scientific culture, in the use of plaster and manures, it has, for many years, been called the *garden* of the State; and is really the most productive and richest county in the State, and the same lands sell for one hundred dollars per acre by the farm. All this has been accomplished by scientific agriculture.

Will our legislature continue to confine all their aid of science, to academic seminaries alone? I approve their aid to literature, for the benefit of the liberal professions; but would ask them equally to foster the great agricultural interest, by establishing ONE AGRICULTURAL COLLEGE, that the sons of farmers, who desire to improve that profession, and raise it above the present state, called drudgery, may do so.

For several years past the farmers in this region have purchased their bread stuffs, and that too at double the former prices. If farming shall become a science, as it will, if properly encouraged by an agricultural college, the present impediments to the growing their own bread corn in all parts of this country will soon vanish, and we shall not again see an agricultural people importing their bread stuffs from a foreign country, when there is no calamitous loss of crops.

Every county and town in the state should address their petitions to the next legislature, asking them to establish an agricultural college, that the farmers may improve and feel the first of the profit and blessing of good husbandry, and all classes will participate, as successful agriculture is the foundation of all our prosperity. What a wide and interesting field do the animal and vegetable kingdoms offer to men of science in agriculture? It is inexhaustible in its pleasures and rewards, both to the mind and the purse. An agricultural college will render the profession of farming more scientific and more honorable, and induce a new class of men of wealth and genius to enter the agricultural field, and the riches and comfort of this country will soon approach nearer to happiness and content.

Let not the demon of party politics prevent the measure, for all parties must profit by improvement in farming. Most respectfully.

DAVID TOMLINSON.

Schenectady, September 5, 1839.

Hints on Building Farm Dwelling Houses—Oil Cake.

Mr. Cultivator—Sir—I am much pleased to notice the interest felt by yourself and some of your readers, on the subject of "Farm Dwelling Houses;" as evinced by the plans given in the last Cultivator. The subject is one of great importance in this country; and without attempting a criticism on the plans you have submitted, I will offer one or two suggestions, which you may receive for what they are worth.

1. Although cheapness and utility are the main requisites, in all plans for all country houses for the farmer in moderate circumstances, yet as the humblest tenement has a moral, as well as an utilitarian effect, both on the incumbent and the beholder, some degree of expression, or architectural effect, should also be aimed at by the builder. The architecture of the cottage and farmery should be peculiar to themselves; and of that picturesque character which will best harmonize with the scenery and occupations by which they are surrounded. For this purpose, small country houses, or cottages, should never be of more than one story, or one and a half in height. The roof might be made very steep so that at least two good square ceiled rooms might be had, together with three or four with inclined ceilings, on the second floor; leaving still an upper garret of dimensions sufficient for a drying room or lumber room. If a piazza and a lobby around the main door were added, (which no cottage should be without,) they would contribute equally to comfort and picturesque effect.

2. The house, instead of being placed on level ground, should always be upon a knoll; and where one does not present naturally, it may be formed by throwing the earth dug out of the cellar around the walls outside. This would not only save something in digging the cellar, which would not need to be so deep in the earth, but it would be drier, and better aired; at the same time that it would give dignity and effect to the general appearance of the building.

3. The chimneys should never, where it can be avoided, be placed in an outer wall. This is an important defect in most houses of this country. The consequence is, a very large quantity of heat generated by the fire, is lost. When they are all in the inner or partition walls, the heat of the back and sides of the fire-places, together with that of the whole chimney, produces a material difference in the temperature of the whole house. A still better plan would be to use Franklin stoves instead of fireplaces, in all rooms except the kitchen, and carry the pipe straight up through the ceiling into a drum in the room above and from thence into the chimney. This would save something in building; as the stoves would not cost quite as much as fire places, with mantels, &c. and greatly lessen the consumption of fuel. The fuel generally contained in a common fire place, is amply sufficient for heating two rooms in this way. This is,

in fact, the most economical mode of heating by fire *in* the room. The new mode of heating by a furnace *without* the room, or the hot water plan, is probably cheaper and better; but is not likely to be adopted very extensively in cottages or farm houses. Some I know would propose close stoves instead of Franklins; but they are detestable things, and cost you as as much in doctors' bills as they save in fuel.

3. When building, it would cost no more to dig the well in the kitchen or woodhouse adjoining, than at a distance, and would be far more convenient. The same may be said of the privy or water closet, which can be as well within as without the house, if properly constructed.

4. There is economy, as well as convenience, in combining all the offices of a farmery as much as possible under one roof. You will find much that would interest your readers on this point, in Loudon's Encyclopedia of cottage, farm and villa architecture, and in the works of several other English writers on cottage architecture that have lately appeared, and the work of a French architect, named Morel Vindé, if I recollect aright. I believe we are far behind the English in architecture in general; and the "snug English cottage and farmery," with alterations to adapt it to the taste and wants of our farmers, would be a great acquisition to our country.

I hope this subject will be pursued by you and your readers; and that we shall have a variety of plans from time to time in your "Cultivator," not only of farm dwellings, but of farmeries and farm out houses, in which picturesque and architectural effect will be combined with cheapness and utility. There is a gentleman in our state, who from the attention he has given to this subject, I presume to be well qualified to enlighten the rest of us. I know not whether he is one of your subscribers or not; if not, he ought to be; if he is—hoping this will meet his eye, I will venture to say to Mr. Lord, that the possession of talents which enables him to serve his countrymen in any way, implies the obligation to do so; and a *hint* to as sensible a man as he is, *ought* to be sufficient. Yours,

D***** F***.

P. S. I made some inquires of you nearly twelve months since, respecting the use of oil cake or flax seed meal, as feed for cattle. Since that time, I have had an opportunity of trying it for myself—having fed eight cows upon it—and I can safely recommend it to such of your readers who are as ignorant of it as I then was, as a most invaluable feed. My cows gave considerably more and better milk than before. Indeed I found it of sufficient advantage to them to pay for giving them a meal of it morning and evening all through the summer, although my pasture has been good and abundant. For fattening calves it is excellent. A little of it mixed with the cow's milk, will do better than to let them run with the cow altogether, at the same time that you save the greater part of the milk.

One of my neighbors has also used it for raising sheep, and another for fattening hogs; and both speak of it in equally favorable terms. Hogs fatten very rapidly on it; and if put upon corn wholly for a short time before killing them, their flesh is said to be as good as if always fed on corn.

Objection to Zinc Roofs—Soaking Seed Corn—Chinese Corn.

Rose-Hill, Flushing, Aug. 21, 1839.

J. Buel, Esq.—Dear Sir—In the "Cultivator" for this month, I notice a communication from Egbert Hawley, relative to the construction of farm houses. Of roofs he says—"shingles are becoming scarce, and inferior in quality, and we must look for a substitute. Slate are expensive, liable to break, and I *suppose* not quite tight, &c. and in casting about for a good covering, *sheets of zinc* have appeared to me to be a desirable article. It has one good quality, at least; it will not rust like tin. Cannot some of your correspondents tell us where it has been tried, and how well it answers? Such knowledge would be very desirable to future builders."

I can inform Mr. Hawley, that "sheets of zinc" were tried upon several of the large buildings in the U. S. Navy Yard at Pensacola, and found *not to answer at all as roofing*. They would leak, although put on with the greatest care, and not a nail would hold where originally driven. The difficulty is, that the metal will *expand* and *contract* on every change of temperature, and to such an extent as to defy all attempts to prevent it. It was found necessary to remove the zinc, and substitute *slate*, which, *when properly put on*, I conceive to be the best article for roof, *quality* and *size* being duly considered.

If metal is desirable in any case, I should select *tin*, of suitable size and thickness, have it well soldered, and then painted. According to my experience, the only objection to tin is, not that it rusts, but, that after a time, however smoothly it may have been put on, it will become wrinkled, and on a cool night succeeding a hot day, it will make noise enough to keep a *nervous* man awake. Respectfully yours,

WM. W. VALK, M. D.

P. S. I planted five acres in corn about the 25th last May, put it in drills 3½ by 1 foot. Soaked the seed in a strong solution of nitre, and to half of it, added as much lime as would adhere. The limed portion came up first, and was 6 inches high when the other was but 1. I counted the seed, and found that it took 120,000—half were pulled, leaving 60,000 to grow. It is now from 9 to 11 ft. high, and promises a *large yield*. Six rows of the "*Chinese tree corn*" are now growing opposite to the above, and merits no further notice than to say it is an abominable "humbug." W. W. V.

The Philosophy of Breeding.

Mr. Buel—Will you be so good as to answer the following question? Will a sow of one breed of hogs, and a boar of another, produce a mixed breed? or will they take after the boar or sow so as to show which they are? It is a question of much doubt, and one which should call forth investigation, as it will throw much light on the best manner of getting a good breed. My impression is, that they will not mix, and if that is the case it would be better to keep the original breeds to themselves, as their habits would be more congenial. If my opinion, in this case, should prove to be correct, the attempt to cross must inevitably be a serious injury; for example, if one half of your stock should be the wood or hunting hog, with long legs, narrow backs and slab sides, and never get flesh enough to prevent them from travelling at least forty miles per day, and the other half with short legs, broad and heavy, and could not travel one-fourth of that distance, the food for one not suitable for the other, and their tempers by no means alike, what might we expect from an unsuccessful attempt at amalgamation? Yours respectfully,

STEPHEN McCORMICK.

Auburn, Fauquier Co. Va. August 28, 1839.

ANSWER.

The progeny of a sow and boar of different breeds, will be a mixed bred, generally partaking more of the male than the female parent, at least in the exterior appearance. If the farmer has a good breed, therefore, he should cross it with a better, or with one at least as good If he has the wood or hunting hog, he should make no cross, but buy and breed from both male and female of improved breeds. A hunting hog will not give half so many pounds of pork for five bushels of corn fed to him, as will an improved Berkshire.—*Cond. Cult.*

A proposition to be considered.

Rahway, Sept. 12, 1839.

Mr. J. Buel—Dear Sir—You have informed the readers of the Cultivator of your intention of closing the present volume of that valuable journal in December, and I presume not one of them have objected to it.—You also shew us the cheapness of it, compared to other journals, and also compared to the other back volumes, which were published at lower prices. The favor that I am about asking of you, will put you in mind of the *old proverb*, "Where much is given, much will be required." I flatter myself, that it will meet the wishes of all your subscribers: at all events, it does of those with whom I have conversed upon the subject, if it will not incur too heavy an expense upon yourself It is this: that you will give us the next volume of the Cultivator folded in the form the Farmers' Cabinet of Philadelphia is folded. It will make it much handier, and altogether a much better proportioned book, and may occupy the front of the book-case, where it will be always at hand as a book of reference. But its present size prohibits its occupying the place it deserves; and the expense of getting it bound (in a manner the book-binders term half-binding) is one dollar, which equals its first cost.

I have taken the liberty of proposing to you this alteration, knowing that you are always seeking for, and willing to adopt, any plan that would be an improvement. If the present price of the Cultivator will not admit of this alteration, I am confident that your subscribers would all agree to advance the price to $1.25 or $1.50; for at either or these prices it would cost but $2 bound, which is the exact amount it now costs.

Yours very respectfully,
WILLIAM A. STONE.

☞ This matter shall be duly considered, and our determination, with the reasons which control it, given in our next number.—*Cond.*

Small Seed Potatoes.

Rahway, Sept. 12, 1839.

Sir—I have made an experiment this season, for the purpose of ascertaining in what manner small potatoes give the best yield, taking into consideration quality and quantity. For this purpose, I selected 30 potatoes about the size of a black walnut with the shell off, and planted them all in one row; 10 of which I planted whole, 10 with the blossom ends cut off, and 10 cut in two. The product was as follows:

The whole ones weighed,	7lb. 10oz.	good quality.
Those with blossom end cut off,	7lb. 13oz.	better.
Those cut in two,	12lb. 4oz.	best.

WM. A. STONE.

Poudrette and Urate.

[We have already published several communications, showing the value of these fertilizing materials, and we give the following communication in further confirmation of their utility—with the remark, however, that they come too much in the shape of quack medicine certificates; and were we not satisfied, from personal experience, of the great value of poudrette, we should be apt to suspect their impartial character.—*Cond.*]

I, Benjamin Lattin Wood, of the town of Poughkeepsie, carpenter, certify, that in May, 1839, I procured two bushels of poudrette. I made a solution of a part of it, and soaked my oats in it about six hours. I was about three weeks behind the usual time of sowing oats, but gathered them about one week later than my neighbors did their oats. They have only been threshed in part, but the yield from them has been first rate. I planted two rows of the common bush bean in hills about two feet apart, and put about a gill of poudrette to each hill, on or about the 20th May, 1839. Previous to the 23d of August I had gathered one crop of green beans, pod and all perfectly tender. On that day there was another crop ready to be picked, and another crop about one-third grown, and the bushes were in blossom also at the time. I have now had four crops from the bushes, of the first quality of beans, and have never ate better. I can recommend truly the use of poudrette for farming and gardening purposes.

BENJAMIN LATTIN WOOD.

Poughkeepsie, Sept. 1839.

On the 26th August, 1839, Mr. Wood exhibited to me a stalk of the bush bean referred to in the above certificate; he said his family had eaten one crop of beans from the bushes, of which I had no doubt from appearances. There was then on the bush shown me, beans fit to eat, another set about one-third grown, and a great many blossoms. On the 9th of September he stated to me, that since showing me the bush, he had had another crop of beans on the vines besides those shown to me, and that new blossoms were still coming out on the bushes, so that, if not killed by frost, he would, according to the then prospect, have six crops of beans in one season from bush beans to which he had applied about one gill of poudrette to each hill. Such a yield I have never heard of before. The ground on which Mr. Wood sowed his oats, was in good order for a crop, but the influence of steeping grain in the solution of poudrette on vegetable matter, shows the quick and powerful influence which poudrette has where the ground is in good condition. It must not, however, be inferred from what Mr. Wood states, that *mere steeping* would produce the same effect on poor ground; I know it would not, from experiments made. For oats, the application of from 15 to 20 bushels per acre, sown in broadcast before the second harrowing, will be all sufficient. A. DEY.

I, George Walton, of the city of New-York, of the age of 56 years and upwards, do certify, that I have been a gardener by profession from my youth. That in the spring of the year 1837 I planted in the yard of Mr. Anthony Dey, in La Fayette Place, in the city of New-York, four young grape vines, namely, 2 Isabella's, 1 Catawba, and 1 Sweetwater. They grew very little in 1837, and not much in 1838, until some time in the early part of the summer, and after there had been applied about two quarts of poudrette to each vine. The earth was removed from around the roots and the poudrette applied to the roots, and then covered over again with earth. Soon after this application, the vines began to grow very rapidly. This year, 1839, there has been applied at three several times about two quarts each time. The vines have grown very rapidly, and all, except the Sweetwater, have a very large number of bunches of grapes this season, such as I have never witnessed before. The Sweetwater was killed down to the ground, but this year has grown stronger and longer than I ever saw before. I attribute this unusual growth and great quantity of fruit to the application of poudrette. GEORGE WALTON.

New-York, Sept. 11, 1839.

I have conversed with gentlemen who have applied poudrette to the mulberry trees, in *different* ways, and comparing the results, I think the best method is, to put around young trees about a gill or handfull next to the roots, in the manner Mr. Walton did about the grape vines; and the quantity may be increased according to the age and growth of the trees. When so applied, the growth has been quick and powerful.

Sept. 1839. A. DEY.

I, William Henry Wright, of Poughkeepsie, farmer, certify, that in the spring of 1839, I made the following experiments in the use of urate and poudrette.

I soaked corn, part in a solution of urate and part in a solution of poudrette, about 12 hours, according to the printed directions, and some was planted without being soaked. There was a decided benefit in all that was soaked, over that which was not. The grain came up quicker, stronger, and of a dark green colour, and grew with great rapidity, and the yield from it was greater.

On other hills of corn and potatoes about a gill was applied to each hill, and the effect was quick and powerful, and have never applied any manure that was to be compared with it in its beneficial results. The potatoes were superior to any I ever saw, both in quality and quantity, and at least two weeks earlier than common.

I soaked also oats about 12 hours, and some not so long, but the result was the same, as applied to the corn, a decided superiority over that which was not soaked, on land in the same condition.

I soaked timothy and clover seed a few hours in Poudrette, and rolled it in lime; the seed has come up well, and there is a manifest difference between it and some that was not soaked. And on the whole, I can recommend it as the best manure I ever tried.

WILLIAM H. WRIGHT.

Poughkeepsie, Sept. 1839.

I have watched with great care and attention the several crops referred to in the certificate of Mr. Wright. The corn was planted from about the 20th of May, 1839, to the first week in June inclusive, some with poudrette in the hill, and some without any poudrette; *but where lime and barn yard manure had been put on the land.* After the corn had been planted about three weeks, I measured some of it, and found that where poudrette in the hill had been applied, it was at least as large again as where no poudrette had been put. The corn with poudrette on it came up apparently stronger, with a dark, rich, green colour, and ripened from two to three weeks earlier in the field than it did in the garden where no poudrette had been applied. On the 18th of August, corn from the field was brought on the dinner table, and was found too hard and ripe to eat as green corn; and therefore I dare presume to say, *that corn, manured with about one gill of poudrette in the hill, even in our worst and coldest summers in which we have been afflicted with frost,* would have ripened sufficiently early to make an entire crop. It was sufficiently ripe on the 1st September to be cut up by the roots and put in shocks to ripen complete. The Mercer potatoes with poudrette ripened some two weeks earlier than other potatoes; and I never ate finer or saw larger potatoes in the month of August. A. DEY.

September 13, 1839.

EXTRACTS.

Experiments with Manures.

[*From the Essex Agricultural Society's Transactions.*]

DANIEL PUTNAM'S STATEMENT.

To the Committee of the Essex Agricultural Society, on Experiments on Manures:

Gentlemen—The following account of experiments in the use of unbleached *wood ashes* as manure, is submitted, that you may make any use of it which in your judgment will render it serviceable to the farmers of the county. In the latter part of August, 1837, I broke up about one acre of low land, (too low and wet to till with ease,) which had become so much bound out that it yielded not more than 14 or 15 cwt. of hay, and that little was of poor quality. After ploughing, I rolled this land, and then dressed it with 40 bushels of wood ashes, mixed with wash (mostly sand,) from the road-side, making probably about one and a half cord; sowed half a peck of herds grass and three pecks red top seed; then harrowed thoroughly and rolled. The seed took well. In 1838, I obtained from this piece of land 35 or 40 cwt. of very good hay, mostly herds grass.

In November, 1834, I broke up a field, dressing it with about four cords of manure to the acre; on a part turning it under the sod, and the remainder putting it on the furrow. In 1835, planted with corn, the crop large; in 1836, without mowing the sod, sowed oats and hay seed. Obtained 40 bushels of oats to the acre. The hay seed took well, but in the following winter was killed by ice forming and remaining long upon the field. In 1837, obtained not more than 15 cwt. of clover to the acre. Thought I must take this field in hand again. In April, 1838, ploughed an acre and a half of it, rolled, dressed with forty bushels of wood ashes, unmixed with any other material, to the acre; sowed oats and hay seed. The oats had a fine growth and the hay seed came up well, but (for I think it best to tell the *whole,*) the rust which visited my neighbors' oats was not kept out of my field by the ashes; I mowed for foddder before the crop had ripened; there was growth enough for forty bushels to the acre. The young grass, too, did not find the ashes a matchless sanative, for its sickness, (in the scorching weeks of August,) which a draught of pure water would have cured, proved mortal.

Shall I tell you, too, what virtue there is in bones? From Mr. Ward, of Roxbury, I obtained, last spring, 20 bushels ground bone, (cost at Roxbury, 35 cents per bushel,) sold one bushel to a neighbor; mixed the remaining 19 bushels with about one cord of soil taken from the side of the roads in the fields where the mixture was to be used. Some of it was used in ten or twelve days after it had been mixed, and some remained in heap five or six weeks. About the 10th of May, when planting corn where four cords of manure to the acre had, the pervious autumn, been turned under the sod, and where I was putting four cords to the acre in the hill, I selected four rows through the centre of the piece, in which I put the bone mixture, at the rate of fifty bushels bone to the acre; no other manure *in the hill.* The corn here looked as well through the season as on the remainder of the piece, and ripened a little earlier. At the time of harvesting, 104 hills on bone yielded 184 lbs. of corn on the cob. The same number of hills in the adjacent rows on manure, yielded 188¾ lbs. That on the bone was the dryest at the time of weighing.

The first week in May, I planted a piece of corn, where I put three and a half cords of manure upon the furrow, and four cords in the hill, to the acre. Through the centre, I left four rows until about the 10th of May, when I planted them with bone, as in the other piece. Here, from 66 hills on bone, I obtained 90 lbs.; from 66 on manure, 96 lbs. Here, too, the corn on the bone ripened earlier, and of course weighed less.

May 21st, when planting potatoes, where four cords of manure to the acre had been turned under the sod the previous autumn, and where I was putting five cords to the acre in the hill, two rows were planted on bone, fifty bushels to the acre. This ground was furrowed only one way, and the hills on the bone happened to be put nearer to each other than those on the manure. When dug, *equal quantities of ground* were taken; of bone, 14 hills; of manure, 12 hills; the bone yielded 55 lbs.; the manure 52.

Between the 15th and 20th of May, I sowed sugar beet, in drills, three feet apart. In some used barn manure, six cords to the acre; in others muscle bed or sea marl, five cords; in others bone, fifty bushels. Three drills of each kind, about three rods long, yielded as follows, viz: from barn manure, 247 lbs.; muscle bed, 355.; bone, 337½.

At the same season I sowed carrots on barn manure, muscle bed and bone. Barn manure, six cords to the acre; muscle bed, 4; bone, 50 bushels. Some of the bone and the other manures were spread broad-cast, and a part of the bone was put in the drill; rows fourteen inches apart. Two rows of each kind, three rods long yielded as follows: barn manure 75 lbs.; bone in drill 105 lbs.; bone spread 82 lbs.; muscle bed 88½ lbs.

I sowed with ruta baga, June 1st, ten drills, three feet apart and fifteen rods long; five drills on barn manure, part of it fresh from the barn cellar and part partially decomposed, nine cords to the acre. The other five on bone, fifty bushels to the acre. Those on the bone were less eaten by the fly than the others, though the others were not very badly injured. A strip (17 feet in length) across the drills, where five had bone and five manure partially decomposed, yielded, bone 248 lbs.; manure 228 lbs.

Another strip 16½ feet long, where there was bone and fresh manure, gave, bone 212 lbs.; manure 227 lbs.

About the 10th of June, I sowed ruta baga on reclaimed meadow land; drills three feet apart; manure nine cords to the acre; bone fifty bushels. Soon after the plants came up, those on the barn manure were nearly all destroyed by the fly; it was necessary to sow a second time. Those on the bone were but very little injured. Four drills, two rods long, on bone, yielded 486½ lbs.; four on manure 439 lbs.

DANIEL PUTNAM.

North Danvers, Dec. 5, 1838.

MR. HOW'S LETTER.

Methuen, December 5, 1838.

Dear Sir—In compliance with your request, I suggest a few ideas, on a subject of no small importance; for success in farming depends principally on the quantity of manure that is made. And, in fact, a locomotive may as well be propelled without steam as a person have good success in farming without manure. There are various ways by which manure may be increased. Cellars under barns for the reception of manure are highly important, as its value is much increased by being preserved from drenching rains and drying winds. Also, the quantity may be much increased by hauling muck or soil, or throwing in hay, straw, or some other materials to receive and suck up the urine, as this is supposed to be worth nearly as much as the droppings. A suitable plan for a cow yard is of no small importance. It should be much hollowing in the middle; the sides so elevated as to prevent the water from running in, consequently there will be but little to run out, to wash out the manure. A large quantity of manure may be made in such a yard, by hauling in muck, soil, or some other material, and ploughing or pitching it over occasionally. But it is said, we have no meadow from whence to get muck; there are no scrapings in the road to be collected; therefore, we have nothing to make compost of. But I would say, if they have nothing else, take the soil from the field, and with a little additional manure, the field may again be restored to its former fertility. Another object of some importance is to have the manure applied in the best manner. I have until recently been of the opinion that it is best to be applied in a green state, and have the fermentation take place in the ground; but of late I have had a different opinion, although I have tried no experiment that is satisfactory in my own mind. I would suggest the idea of recommending a premium to be offered for the best experiment on the application of manure, that it may be ascertained which is the most profitable, to apply manure in a green state or to make a compost of it by mixing other materials, taking into the account all the additional expense of labor.

Another thing is, to keep the hogs at work. By keeping a good supply of hogs and accommodating them with materials to work with, they will add much to a farmer's stock of manure.

Some farmers are averse to the credit system; to supply their hogs with materials to work with; to fill their cow yards and barn cellars with muck, &c. and to give one, two, or three years credit is too much. This is one important reason why so little improvement is made in farming. I believe there are the materials on almost every farm, and means within the reach of almost every farmer, to enrich his farm to almost any extent.

Suppose a person to make a certain additional quantity of manure; consequently in the same proportion the products of his farm will be increased, from which, by spending on the farm will again increase the manure, and so on, until his farm may be enriched without limit. Finally, I believe that if all the farmers would pay their attention to making manure and enriching their farms that their interest requires, the western fever would be less prevalent among us, and our young men, instead of leaving the farms of their sires and engaging in speculation, or emigrating to the far west, would cultivate the land of their fathers and learn from experience that they may be amply repaid for all their toil, and that the cultivation of the earth is second to no other employment. Yours, with sincere respect,

JOSEPH HOW.

Vegetable Kingdom,

A term including all plants and roots which grow above and under ground; being nourished by the air, water, &c.

Vegetables may be considered, botanically, as to the apparent parts of the plant, of which we have already treated under *Botany:* or physiologically, as to the organization of the plant: or anatomically, as to its component, or chemically, as to its constituent parts.

In treating of Botany, we have given an account of the parts employed in classification according to the prevailing systems of *Linnæus* and *Jussieu;* the one founded on the sexual organs, the other on the cotyledons that envelop the seed.

Physiologically, a plant may be considered as composed of roots, stem, branches and leaves.

The roots are formed by the growth of that part of the seed called the radicle, whether by extension of parts already formed, or by apposition of new parts derived from the food according to the laws of organic crystallization, is not accurately known. The roots are the mouths of the plant: by the property of irritability dependent on organization, they are attracted to move in that direction where food is to be found.

The food of plants consists in those substances only which are found by experiment to be universally, in all cases and in all places, the component parts of a plant, viz. carbon, hydrogen, oxygen, sometimes azote and alkali. The siliceous, calcareous, and magnesian earths, the earthy salts, and the iron and manganese found in plants, vary in quantity according to the circumstances of soil, climate, and manure artificially applied. All of them may be wanting in a plant, and yet the plant be perfect. Hence manures that increase the substance of the plant, are such as are decomposable into carbon, hydrogen, oxygen, azote and alkali: the other kinds of manure, are those that stimulate the irritable fibre of the plant to stronger action, as salt, plaster, lime, &c.—those that increase or decrease the tenacity of the soil in which plants grow—those that act by increasing or decreasing the capacity of the soil to retain moisture.

Plants, however, do not exclusively feed by their roots. A very great part of the nutriment of all plants is derived from the carbonic acid of the atmosphere, which the leaves decompose, feeding on the carbon and throwing out the oxygen—and form the atmospheric moisture which the leaves drink as well as the roots. The effect of atmospherical electricity, as a stimulant or a sedative, we have not facts enough to form any opinion upon. Light is certainly consumed by plants, and enters into their composition, being almost the only source of colour, and probably of the light emitted during combustion. Leaves also perform the office of lungs to a plant.

Plants may be considered anatomically, as composed of the epidermis, the thin skin that covers the bark—the bark analogous to the skin of animals—the wood (liber)—the pith—the sap—the tracheæ or air vessels—and the cellular tissue, analogous to the cellular membrane of animals.

The systems of the vegetable are analogous rather than similar to those of animals: they have the woody stem, analogous to the osseous system of animals—a system of vessels for the sap to ascend—another wherein the recent sap is eliminated into the peculiar juices of the plant, analogous to our glandular system—a system of vessels wherein the charged sap descends and nourishes the plant—leaves analogous to lungs—and excretory vessels, as well as the secretory vessels which we have noticed as analogous to our glandular system.

Plants are young, grow by feeding, digesting, and assimilating their proper food; they arrive at adult age and full growth, they beget offspring by sexual commerce, they are subject to disease, to accident, to be preyed upon by parasite plants, to grow old and die.

They have irritable fibre, analogous to our muscular fibre, and like this, contractile on the application of stimulus. It has not yet been ascertained, that they have any system analogous to our nervous system, hence they have not (so far as we know) any apparatus to authorize us to ascribe to them sensibility, sensation, or voluntarily: though in some plants noticed by Dr. Smith, the English Botanist, when one part is stimulated a distant part contracts, so as to suggest a common sensorium.

All these properties of plants, depend upon their organization: they are developed as the organization is developed, they are complicated and perfect in proportion to the organization; they are injured when the organization is injured; and they disappear when the plant becomes disorganized; analogously to the faculties or properties called mental in man. What is the immediate cause of organization, vegetable or animal—or in what way that principle causes an assimilation of parts derived from the food employed for nourishment—or whether the lowest forms and modes of organized matter depend on accidental apposition or approximation of particles separately unorganized—we know not in our present state of knowledge. Whether life depends on the property of organization, or the property of organization on communicated life? are questions, curious, but useless, in proportion as they are abstruse.—*Domestic Encyclopedia.*

Wintering Bees.

[*From the Genesee Farmer.*]

Mr. Tucker—Agreeably to your request, I called on Mr. Eggleston, and obtained from him the following statement of his method of wintering bees, and the success attending it.

In the fall of 1837, he buried 30 or more hives, and the following spring they were taken out without the loss of any. In 1838 he buried 10 hives, with the same success, but lost 7 or 8 hives of bees that stood in his bee-house through the winter. He says that he finds very few, or no dead bees under his hives that are buried, and that they winter on much less honey than when left in the house; some small swarms have lost but 3 lbs. in weight in wintering, and the largest but 10 lbs. He has buried his bees or some of them, each year, for four years past, and has not lost a swarm that was buried, and shall hereafter bury all that he intends to winter; he has now about 40 swarms. Another fact—those that are buried do much better, and swarm much earlier in the spring.

Mr. Eggleston's method of burying his bees, is to dig a shallow trench in the ground, long enough to set the number of hives he wishes to bury, with a gentle slope in the trench, to carry off the water if there should any collect, and then place the hives in the trench, raised a little from the ground by a small stone under each corner of each hive, then covers them with straw and lastly with dirt, to use his expression, as you would a pile of potatoes, so deep as not to freeze under the hives.

As to the success of Mr. Eggleston in preserving bees, as described above, there can be no doubt, as it is known to all his neighbors, who (if necessary) will certify to the facts as stated. Yours, respectfully, ANSON ANDREWS.

Reading, August 20, 1839.

Agricultural Geology.

[*From Prof. Jackson's Third Geological Report.*]

CONCLUDED.

In order that a plant should absorb the requisite nutricient matters, it is essential that its rootlets should have free play, and hence the necessity of a proper texture in soils. It is also requisite that the materials should be rendered in some degree soluble; and that the soil remain permanently good, it is essential that it should not be too loose in its texture; for, against the opinions of some farmers, I still maintain that the principal and most active ingredients of manures and soils, are lost by solution and infiltration; the evaporation being as it were but a drop in the bucket. On this point however, I shall present some considerations hereafter.—There is also another property of soils too generally lost sight of, namely, their electro motive power, and their influence in this manner, upon the absorbing spongioles of the radicles, producing the effect called by M. Dutrochet, *endosmose* or *internal impulse*. This effect is most assuredly produced by those mixtures and combinations of mineral matters and salts, with vegetable humus, which characterize luxuriant soils. Here, then, is a new field of research for the philosophical farmer, who will find the still small galvanic currents which take place among the particles of soil, are busy preparing his bread. The influence of electricity has long been known to hasten vegetation, and plans will ultimately be adopted to bring the results of the laboratory into the hot bed and green house, while a contemplation of the phenomena will illustrate those great natural laboratories—the corn-fields of the farmer. A soil consisting of *one kind of earth, is barren*—no matter of what earth it may be composed, whether silex, alumina, lime or gypsum. *Pure vegetable matter, is also barren; but proper combinations or mixtures of three earths, always produce fertility*, provided the *pabulum* or food of the plant be present also. Certain saline matters are said to stimulate plants, and by this I understand that they produce electrical movements or endosmose, for they will act in a similar manner upon dead or inorganic matter, as seen in Dutrochet's experiments. By saline stimulants, the foliage of plants is rapidly and substantially developed, owing to the absorption of carbonic acid gas from the atmosphere, and the retention of its carbon, while the oxygen gas is exhaled by the green leaves. And since such stimuli tend only to the development of the foliage, and act against both germination and ripening, the proper time to apply such substances, is after the plant has shot up, and before it begins to ripen its seeds or fruits.

These principles are generally unknown to farmers, and hence their unskilful appplication of gypsum, salt, &c. as dressings to soils. They also neglect to consider the native *habitat* of their plants, and hence often apply the wrong stimuli. Now it is evident, that since asparagus plants, onions, cabbages, and similar vegetables, are native plants of the sea-coasts of those countries, to which they are indigenous, that if they are to be cultivated in soils free from saline matter, salt may be advantageously used in small quantities, to render them more luxuriant. Gypsum and sea salt have nearly the same effect upon plants, and hence when the soil derives saline matter from salt-water spray, or vapor, gypsum will not benefit the soil, or act as a stimulant upon plants.—This opinion, which is proved in the Prize essay of Professor Le Cocq, on saline manures, explains the fact well known in Maine, that gypsum exerts but little action upon the soils near the sea-coast, but does act favorably on the soils of farms situated in the interior of the State, especially on those which contain small quantities of carbonate or geate of lime.

As I have formerly stated, it is evident from an examination of the mineral ingredients of soils, that they *all originated from the decomposition and disintegration of rocks, which for ages have been acted upon by air and water;* those agents having, by their mechanical and chemical powers, shivered and crumbled the solid ledges into those pulverulent matters which form the basis of all soils—to which, subsequently, small quantities of vegetable humus are added by the decay of plants.

ANCIENT SOILS. There have been various epochs in the earth's history, when soils were thus formed, and after bearing their luxuriant vegetation, were reconverted by aqueous and igneous causes, into rocks, the structure, and fossil contents of which, denote their origin to have been from sedimentary matter, hardened by pressure and heat. Thus, when we look back to the epoch of the transition formations, we find the rocks composing that series to be composed of agglomerated sand and pebbles, cemented by clay, which presents itself in an indurated form, the results of igneous action. Marine shells, contained in the graywacke rocks just described, evince that this deposite was chiefly formed beneath the waters of the sea, while some portions of it were deposited in fresh water, as proved by the presence of certain plants, peculiar to bogs and lakes. The slates of this formation contain prints and casts of numerous plants—such as ferns, equisetaceæ, lepidodendræ and stigmaricæ; while beds of anthracite coal, shewing by their structure and composition their vegetable origin, are also included between the strata.

Now it is evident, that the above mentioned plants could not have grown without a soil, and the rocks in which they are imbedded bear every proof that they were once in that condition.

SECONDARY SOILS. We come next to the secondary epoch; and here again we are astonished to find proofs of a numerous succession of alternating beds of soil, each having, for long periods of time bore their perennial verdure of intertropical plants, allied to those above noticed, but more complicated and perfect in their structure. The sandstones and shales of this formation are vast herbariæ of ancient vegetation, and their strata contain, well preserved between their sheets, perfect impressions of numerous genera of plants, the species of which are now extinct. Large trunks of trees are also exposed by opening coal mines and quarries of sandstone, while the numerous and reiterated strata of coal itself also bear ample proofs of their vegetable origin.

Here, then, we have another epoch, at which soils existed, produced their abundant vegetation, stored the earth with fuel, and then were reconverted into solid rocks, to be again subjected to the wear and tear of elemental strife.

The TERTIARY EPOCH was of a milder character, and but little disturbance of the solid rocks appears to have been effected during those submersions, when the plastic clay, calcareous marls and strata of perfectly preserved marine shells, were deposited. These sedementary matters appear to have resulted from a slow and gradual deposition of clay and other fine sedementary matter, which beneath the sea became soon inhabited by numerous shell fish, and were imbedded in succession as we now find them, since the elevation of the land above the encroachments of the sea.

When we consider the several periods which I have briefly mentioned, it will at once reveal to any reflecting person, that the world has been during the lapse of inconceivable ages, subject to great revolutions in its geological organization. At one time, the rocks are worn down into soils, and bear their vegetation—then continents were sunk in the ocean's depths, and subsequently were raised again, the soils having in the mean time, been converted into rocks. By such considerations, we soon learn to respect the antiquity of the world; and knowing that such records are legibly written on the tablets of stone, we feel a natural desire to read and understand their meaning.

ANCIENT ALLUVIAL SOILS, OR DILUVIUM. Subsequent to the epochs of which I have spoken, we find that another scene of violence disturbed the tranquillity of the great deep, and the northern ocean was hurled, with its seas of ice, over the land, sweeping the loose materials from the very mountain tops, and depositing them far south of their former resting places—while the grooves, scratches and water marks upon the surface of the fixed ledges, shew the direction in which the current passed. By such a flood, (proofs of which are nearly universal in Maine, as elsewhere,) the soils were transported and commingled, so that we rarely find a soil similar to the rocks beneath it, but identical with that derived from other rocks, which occur to the north and northwest.—Having already cited so many localities in proof of this position, I shall not here recapitulate, and the intelligent observer will find so many illustrations in Maine, to satisfy his rational curiosity on the subject, that he need not long remain in doubt as to the facts.

MODERN ALLUVIAL SOILS. The present causes which act upon the solid rocks, are both chemical and mechanical.—Oxygen, from the atmosphere and from water, is constantly affecting some portions of the work, especially where the rocks contain pyrites. Rivers, torrents, brooks, and even rain, are gradually sweeping away the solid rocks, by their continued action; but more powerful than all others, is the action of freezing water, which, by an almost irresistibly expansive force, rends all rocks, into which water can find a passage, and crumbles down those which are porous in their structure. Upon the coast, the sea ever beating the solid rocks and hurling the loose fragments with the force of battering ordnance against the shores, wears away the ledges, the detritus being either spread out on the bottom, or sifted up at the mouths of harbors and estuaries.

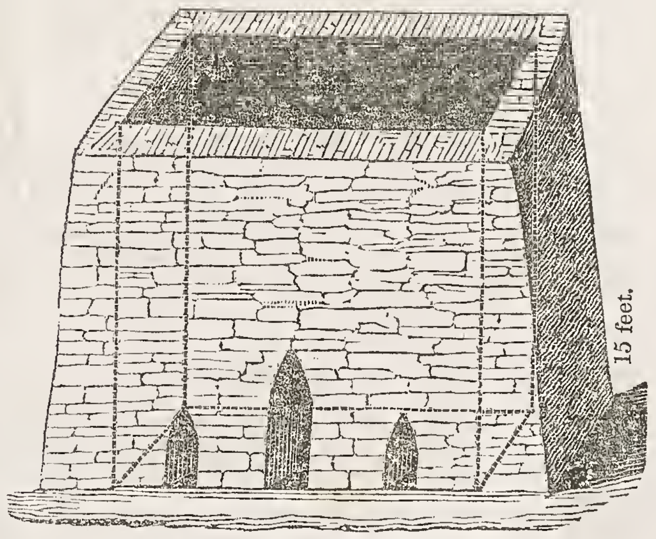
Alluvial soils are produced by the transportation of fine particles, by aqueous agency, from higher sources, and are especially brought down and deposited during freshets, when a river bursts its confines, and being diminished in its velocity, deposites its sedementary matter over the intervales. The force of the wind is also constantly removing fine particles of soil from one district to another, and the dust of ages is of greater importance than is commonly believed. Enough has been said on this subject to excite inquiry, and to stimulate others to look over the pages of nature, for their own satisfaction, and this is all that can be expected from introductory remarks, such as I now offer to the reflecting observer.

REMARKS ON LIMESTONES.

A tabular view of the chemical composition of each variety of limestone, analyzed in my laboratory during the present year, is herewith subjoined. From this table, it is easy to fix the relative values of each kind of rock, and to learn how they will burn in the kiln. Many of them will bear the heat requiste for converting them into lime, by the discharge of the carbonic acid gas, at a full red heat; others must be burned more slowly and with a gently increasing fire, which may be ultimately driven to a dull or cherry redness. All those marked as good, will slake perfectly, after being burned, and are sufficiently pure for all ordinary uses. They are generally free from magnesia, and hence are better adapted to agricultural use, than the magnesia limestones. Magnesia will remain a long time exposed without absorbing its equivalent of carbonic acid, and thus it does not act favorably, excepting when thoroughly saturated by the fermentation of compost, or by long exposure to the air. When such limestones are skilfully managed, they answer nearly as well as the pure lime. The argillaceous matter contained in some of the limestones, that occur imbedded in slate rocks, does no harm to the soil, and is even beneficial in some cases. The Dexter and Guilford limestones will make a good and strong mortar, and will also prove very valuable in making compost, or for the treatment of soils by liming. So will also many of the other varieties hereafter mentioned in the tables.

Under the description of each locality, I have made ample observations on the nature of the lime-rock, and shall here present some views or plans of such kilns as may be required for the conversion of the rocks into quicklime.

[Fig. No. 40.]—15 feet.



Lime Kiln for burning 300 *casks of lime at a time.*

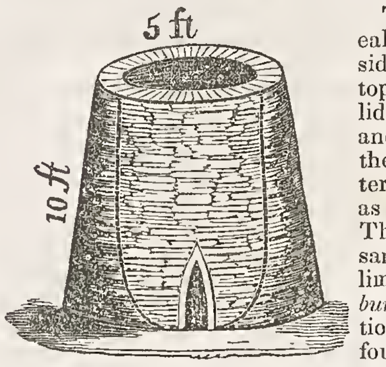
Fig. 40. Kiln built of refractory rocks, lined with clay, and laid outside with mortar—fifteen feet wide—fifteen feet high—five feet back. Arches—middle, five feet high—side arches, three and a half feet high.

This kiln is of the form commonly used at Thomaston, and the lime is burned by means of wood fuel—thirty cords of wood being required to burn the charge of rock. The operations are divided into four turns, and from three to four days and nights the fire is kept unremittingly in action. At the close of the operation, the limestone is found to be converted into caustic lime. A more full statistical view of this business, may be seen in my former Reports on the Geology of Maine. It is necessary, in case the rock is liable to slag, that it should be broken into pieces of pretty uniform dimensions, or at least, care must be taken to place the larger masses near the fire, and the smaller ones more distant from it. The arches are to be built up of large angular pieces of the rock, not more than six or eight inches in diameter, and they must be laid loosely, so that the flame may penetrate freely through them, and act upon the superincumbent mass of broken lime-rock. I have seen some persons break the limestone in the kiln. This should never be done, for the small pieces fill up the interstices in the charge, and prevent the passage of flame and heated air, required for the draft of the kiln.

In laying the arches of limestone, make them coincide with the arches of the kiln—pack the pieces so as to allow the passage of the fire, and lay the limestone in a very loose manner, until the kiln is half full. Then you may throw in the smaller pieces in confusion, and fill up the kiln to the top. This being done, place your fuel in the arches and kindle your fires, and drive them until the lime is sufficiently burned, which may be from three to four days and nights, according to the kind of rock, and the intensity of the fire.

A smaller kiln may be required in some towns, and in cases where the farmer burns his lime for his own use only. I therefore, herewith present a plan for such a kiln.

[Fig. No. 41.]



This kiln is of a cylindrical form, rather wider outside at the bottom than at the top, so as to give it more solidity. It is ten feet high, and five feet in diameter at the top, while the bottom internally contracts a little, so as to support the charge.—This contraction is unnecessary, excepting where the limestone crumbles or "*fine burns*," during its calcination. The arch may be made four and a half or five feet high, and two and a half or three feet wide so as to allow room for discharging the lime, after it is burned. The kiln may be made of any rock, capable of withstanding a full red heat. Talcose slate, mica slate, or even common clay slate, will answer. It must be pointed with clay inside, and with mortar on the outside. In charging this kiln, the stone is broken into suitable sized pieces, and an arch is built up, corresponding with the arched opening and extending quite across the diameter of the kiln. Having laid up this arch loosely, pack the kiln in a careful manner, until it is half full of the broken limestone; then you may throw in the smaller pieces on the top, and fill the kiln entirely. It is now set for burning, and you have only to place the wood and kindle a fire in the arch, keeping the heat gradually increasing, until the limestone is sufficiently burned. This may be known either by the time required, or by the appearance of the pieces at the top of the charge. It will generally be noticed, that when the fire has done its office, that the smoke ceases to appear at the top of the kiln, and a flame rises through the interstices at the top. The charge begins also to settle a little. The time required for the burning of lime, varies with the different kinds of lime-rock, and hence it is alone to be learned by experience in a particular case, and with the kind of kiln with which the lime burner is acquainted. One or two fair trials, will teach any intelligent man how to do the work in a proper manner.

The cost of the lime prepared in a small kiln, is always a little more than when it is made in a large way; hence where an extensive demand exists, the three hundred cask kiln would prove the most profitable to the manufacturer.—Most of the limestones here described, may be burned at the cost of twenty-five cents per cask, in bulk—or for fifty cents, packed in casks. Where it is to be used on the spot, in agricultural improvements, it may be thrown out of the kiln, and allowed to slake itself, and then is ready for immediate use. Its weight is increased from thirty to fifty per cent by slaking, and its bulk is tripled or quadrupled; hence, where it is to be transported to a distance, it is better to take it in its caustic state, either in bulk or in casks.

A shed ought to be built near the kiln, so as to keep the lime under cover, to prevent its being wet by rain.

Rock, fresh from the quarry, burns more easily than after it has become dry by laying exposed to the action of sun and air.

Limestones, containing pyrites, like that at Brown's corner, in Clinton, give out sulphurous acid gas during the process of burning, and in such cases, it is unpleasant to have the kiln near the house. In all cases, at the commencement of the operation, much smoke is produced, and it is. therefore, convenient to place the kiln where people are not likely to be annoyed by it. When driving the fire in a lime kiln, you perceive that the limestone melts or slags, you must not increase the heat beyond that point.

Poor limestones are frequently burned best by means of wood that is not perfectly dry, so as not to burn too rapidly. A little experience and discretion, however, will teach any man how to regulate the fire, so as to make the best kind of lime.

By examining the tables, knowing how one kind of limestone burns, you may judge of the others which are there presented. Nearly every variety of limestone found in Maine, I have burned in my laboratory, and know, practically, exactly how they will burn, and the quality of lime that will result. Where the oxide of iron is more than two per cent the lime will have a brownish tinge, so as to render it unsuitable for plastering ceilings. The slate is merely inert, and gives an ash grey colour to the lime, where it abounds.

Silex, when chemically combined with the lime and oxide of iron, forming what are called by chemists *silicates of lime and iron*, produces a hydraulic limestone, liable to melt at a full white heat. It is frequently a valuable article for making hydraulic cement, and abounds in several places in the State, especially at Machias, and at the forks of the Kennebec river. Many of the rocks described in the catalogues appended to this Report, as calciferous slates, will also make hydraulic lime. They may be burned at a red heat, but beyond that temperature run into a deep green glass or slag.

Tabular View of the Analyses of Limestones collected during the Geological Survey of 1838.

Number.	Locality.	Variety.	Cabonate of Lime, per cent.	Insoluble matter, per cent.	Oxyde of Iron, per cent.	Lime, per cent.	Remarks.
1	Abbot: Ira Witherum,	Blue—dull,	74.0	24.8	1.2	41.9	Good.
2	Athens Road,	Greyish white; crystalline,	70.4	25.2	4.4	39.6	Good for agriculture, makes brown lime.
3	Athens Village,	Bluish, compact,	72.6	2.8	....	40.8	Good for agriculture, slags at white heat.
4	Bingham,	Reddish brown, dull; micaceous—hard,	42.6	55.8	0.6	24.4	Poor, not worth burning for lime.
5	Carthage: B. Winter,	Light grey; granular, containing mica,	89.8	8.8	1.4	50.4	Bears full burning; good for mortar and for agriculture.
6	Do Mr. Reed, No. 2,	Reddish white,	76.2	23.4	0.4	42.8	Good; burns easily; liable to slag if over-burned.
7	Clinton: J. D. Burrell,	Bluish grey, slaty,	47.2	50.4	2.4	26.5	Poor; burns at red heat; slags; makes brown lime.
8	Clinton: L. Brown,	Bluish, containing slate and pyrites,	5.40	43.0	3.0	30.3	Slags at full red heat; makes brown lime; rather meagre, but good for agriculture.
9	Clinton: A. Brown,	Blue, interstratified with thin folia of slate,	76.8	17.2	0.6	43.1	Good; bears full red heat; makes a fair lime.
10	Dexter: E. Crowell's,	Blue, interstratified with thin folia of slate, containing small veins of calc. spar,	90.0	8.6	1.4	50.6	Very good; bears full red heat; makes nearly white lime.
11	Dexter: Mr. Fish,	Bluish, mixed with small veins of quartz and slate,	89.2	9.6	1.2	50.1	Good; like the above.
12	Dexter: L. Pullen's,	Bluish, compact; interstratified with thin folia of slate,	78.2	20.0	1.8	44.0	Good; but not quite so strong as the preceding.
13	Dexter: John Puffer,	Bluish, slaty; compact,	84.0	14.4	1.6	47.2	Good; makes strong lime.
14	Dixfield,	Bluish, with crystals of actynolite,	69.4	29.2	1.4	38.9	Burns at red heat; slags at higher temperature: slakes coarse.
15	Dover, south side of river,	Bluish grey; mixed with slate, calc. spar and qurtz,	70.6	25.4	4.0	39.7	Burns at a full red heat; slags at white heat; makes brown lime.
16	Dixfield: Mr. Holman's,	Dark bluish grey, dull; micaceous, containing small crystals of actynolite,	79.6	20.0	0.4	44.7	Burns solid at a full red heat; slags at white heat; good lime.
17	Dover,	Bluish grey; seams of calc. spar, containing slate and quartz,	70.6	25.4	4.0	39.7	Not so good as the above; makes brown lime.
18	Farmington, Titcomb's Hill: J. D. Coney's,	Dull bluish; mixed with slate,	88.8	6.4	4.8	49.4	Bears a full red heat; slags at a white heat; makes brown lime.
19	Farmington Hill: D. J. Coney,	Bluish, slaty; mixed with mica slate,	84.4	14.4	1.2	47.4	Like the above; but makes a better colored lime; ash grey, white when slaked.
20	Forks of Kennebec: Mr. Foster. Recommended for hydraulic lime,	Buff-colour; compact, stratified,	45.4	silex 27.0 a8.2	*	30.5	Good for hydraulic lime, to be burned at red heat. Runs into glass at white heat.
21	Foxcroft Falls,	Light blue; containing calc. spar, pyrites and slate,	35.6	62.0	2.4	19.9	Too poor for lime, but will answer for flux to iron ore.
22	Foxcroft: Cave near river,	Bluish; interstratified with slate containing pyrites,	48.8	47.8	3.4	27.4	Poor; good only for flux to iron ore.
23	Guilford: River,	Dark blue,	84.8	13.8	1.4	47.6	Good; bears a full red heat; makes white lime; will answer for all ordinary uses.
24	Hampden,	Blue, slaty, hard; not good,	5.0	93.2	1.8	2.8	Turns red in the fire; is not suitable for lime.
25	Harmony,	Bluish, slaty,	61.4	36.4	2.2	33.9	Burns at a red heat; slags at a white heat; makes a poor brown lime.
26	Industry: on Farmington Road,	Blue, micaceous, containing blue calc. spar,	76.0	21.2	2.8	42.7	Good; bears a full red heat; makes a brown lime.
27	Jay: Mr. Noyes,	White; crystalline, containing quartz and actynolite,	†				
28	Livermoro Falls,	Grey, with numerous crystals of actynolite,	62.8	34.0	3.2	35.3	The lime burns white, but is full of crystals of actynolite, but will answer for agriculture.
29	Mount Vernon,	Greyish white; granular; numerous crystals of actynolite, mixed with mica slate,	48.8	47.0	4.2	27.4	Bears a full red heat. The lime is white, but is full of crystals, that make it coarse. It will answer for agriculture.
30	New Sharon: J. Bean,	Blue, mixed with mica slate,	53.8	36.0	10.2	33.1	Bears a full red heat. The lime contains brown scales of mica, & is dark brown.
31	New Sharon: J. Winslow,	Light blue; micaceous,	77.0	20.6	2.4	43.3	Good; makes fair lime, of a brown colour.
32	New Sharon: S. Tollman,	Light blue; micaceous,	88.2	10.2	1.6	49.6	Good; less brown than the above.
33	Norridgewock: S. Sylvester,	Bluish, mixed with slate,	88.2	10.6	1.2	49.0	Good; burns solid; slakes well; is light brown, but strong.
34	Norway: W. Parsons,	Greenish grey,	51.4	47.6	1.0	28.8	Makes a weak lime; slags at full red heat.
35	Norridgewock: A. Wood,	Dark blue, micaceous,	51.2	48 4	0.4	28.7	Weak lime; slags at high red heat.
36	Phillips: I. Whitney,	Granular, stratified with dark and light stripes,	64.8	34.4	0.8	36.3	Makes good lime; fine, burns a little; will slag at a white heat.
37	Phillips: E. side Co. Road,	Greenish grey, compact,	67.6	26.8	5.6	37.9	Weak, slags; makes brown lime.
38	Phillips: I. Whitney,	White; granular,	65.0	34.6	0.4	36.5	Like the other variety; fine, burns a little.
39	Phillips: W. side Co. Road,	Greyish white,	5.2	88.2	6.0	2.9	Not good for lime.
40	Poland: N. Bray,	Greenish white; granular, containing actynolite,	43.6	54.4	2.0	24.4	Makes brown lime, coarse when slaked.
41	Rumford Falls,	Greyish white; crystalline, with crystals of actynolite,	78.0	20.8	1.2	43.9	Fine, burns; but makes a good strong and white lime; good for all usual purposes.
42	Skowhegan Falls,	Bluish grey, mixed with a little slate,	52.6	38.6	3.8	32.3	Good for agriculture, but is brown coloured.
43	Strong: Norton's Mills,	Containing calc. spar, mixed with a little slate,	90.5	8.4	1.0	50.8	Good for lime; makes a good mortar.
44	Temple: I. Varnum,	Bluish grey, dull, micaceous, containing spots of iron,	70.2	28.4	1.4	39.5	Burns at red heat; slags at higher temperature; makes light brown lime.
45	Thomaston, Beechwood Q. hard stone,	Stratified with blue and grey stripes,	55.6	2.8	‡1.2	31.2	Burns solid; slakes well; makes good white lime for mortar.
46	Turner: S. Davy,	Greyish white; granular; with crystals of actynolite,	74.6	25.0	0.4	42.9	Good; burns to good lime, but contains crystals of actynolite, and is coarse.
47	Turner· Oak Hill,	Greenish grey; granular,	40.0	59.0	1.0	23.7	Not good; will not make lime.
48	Union,	Brown; with numerous pieces of hornblend,	9.8	32.0	58.2	5.4	Not good for lime.
49	Waterville: Gen. Robinson	Bluish, dull, interstratified with slate,	47.2	47.2	5.6	26.5	Too weak to make a good lime.
50	W. Waterville: Great Falls	Bluish, interstratified with thin folia of slate,	73.8	24.8	1.4	41.4	Good for agriculture; makes lime of a light brown colour; slags at white heat.
51	Do Mr. Crowell's	Light bluish, interstratified with thin folia of slate,	89.8	9.0	1.2	50.4	Good; makes light brown lime.
52	Winslow: James Wall,	Light bluish grey, with small veins of calc. spar,	73.8	24.2	2.0	41.4	Good for agriculture; makes brown lime.
53	Winslow: T. Simpson,	Light grey, dull, coated with slate,	68.4	31.0	0.6	38.4	Burns at red heat; slags at higher temperature; makes weak lime.
54	Do Mr. Drummond's	Blue; interstratified with slate,	81.8	16.2	2.0	45.9	Good; burns at full red heat; slags at white heat; makes brown lime.
55	Winslow: Mr. Forbur,	Dark blue, mixed with a little slate,	77.8	20.6	1.6	43.7	Good; burns at red heat, and slakes light brown.
56	Winthrop: J. Richard's,	Dark granular,	78.8	20.2	1.0	44.3	Good for lime; burns well at intense red heat; makes a solid lime, that slakes well, and is full of scales of mica. It is strong.

* Carbonate of iron 2.8 per cent. Silicate of iron and manganese 2.4 per cent. Magnesia 5.0 per cent.

† Not good—rejected as useless.

‡ Carbonate of magnesia 39.4 per cent.

[We append the following, from Professor Ducatel, as interesting to a portion of our readers.]

"The mode of conducting the operations of the *perpetual kiln* in the state of New-York, in which *anthracite* is burnt. is as follows:—The coal and stone are arranged in alternate layers. The first charge is made by constructing a grate over the *eye* with large stones fitted in loosely and sufficiently apart, to allow the kindling of the coal, of which a layer is first put on: the stone is then *lowered* down upon it, and properly disposed of by hand, and so on alternately with the coal, until within eight feet of the top. The kiln is then fired from below, and at the expiration of four days the whole being ignited, more stone and coal are thrown in. The coal should *not* form a complete layer over, or covering to the stone, but a little more than fill up the interstices between the peices, and care must be had not to allow too much of it to settle round the walls, as the heat would destroy them: the kiln is then finally dressed off with smaller stone. The morning of the next day after this operation, the kiln is opened at bottom, and from 90 to 100 bushels are taken out to be slaked; this is repeated in the evening. and successively every morning and evening without interruption.—When the materials in the kiln have sunk down to within six or eight feet of the top, fresh supplies are added, and this is continued indefinitely.

At Barnegat, as soon as the lime is taken out, it is slaked by using two pails of water for about 3 and 1-2 bushels of lime; and before being shipped, (for most of this lime is used for agricultural purposes,) an additional quantity of water is thrown over it. One ton of coal, it is supposed, will burn over 200 bushels of lime. The lime-burners here are of opinion that the stone may be used indiscriminately, of all sizes, but this is an error; the universal practice in Europe being, to break it down to the size of the fist.

Wood, charcoal, peat, bituminous coal, and especially coke, are also used in *perpetual kilns*, and the arrangement of materials, as well as the relative proportions of each to be employed, will vary according to the nature of both. When coal is used, its layers should be thicker in the centre than on the sides, in a ratio of difference of 4 to 3. In those kilns that are provided with two or more fire-places, choice must be made in kindling of that towards which the wind is setting, provided it be not too strong. It is always important to try to obtain an equal fire throughout each successive layer,—but this is not always easily effected, because it frequently happens, that the combustion goes on more rapidly in one direction than another, which is partly owing to the layer of stone being thicker on the sides, and also less supplied with coal. Those parts of the kiln where the fire has become checked may be discovered, by remarking that in such places the stones are not so discolored by smoke, as where the fire is more regular. The lime-burner is then immediately to turn his attention to those spots, and with his poker clear the impediments to the free circulation of the air. The perfect calcination of the inferior layers of stone, is generally indicated by a great diminution of smoke, which usually takes place when the fire has reached about the three-fourths of the height of the kiln. The practice in Europe is then to take out all the lime that has been made, (being about two-thirds of this same height,) or as high as where pieces of ignited coal are observed intermixed with it. It must be taken out with care: for a sudden fall would endanger the result of the operation."

Agricultural Chemistry.

BY HENRY R. MADDEN, ESQ. L. R. C. S. EDINBURGH.

[*From the Edinburgh Quarterly Journal of Agriculture.*]

2. *Inorganic or Mineral Manures.*—In our last we completed a short sketch of the composition of the animal, vegetable, and vegeto-animal manures which compose our division of organic manures: we shall, therefore, at once proceed to make a similar examination of those substances belonging to the mineral kingdom, which farmers are in the habit of employing for the purpose of enriching their land.

We have before remarked, that these substances act in a manner totally distinct from organic manures, the reason of which is obvious, because they *cannot* be, from their nature capable of supplying either of the four elements, viz: *carbon, oxygen, hydrogen* or *nitrogen*, which, as we have so repeatedly stated, form the essential constituents of all plants; we must therefore look to other circumstances besides the mere nutrition of vegetables, in order to explain the true cause of those beneficial effects which, beyond doubt, result from their judicious employment.

The advantages to be gained by the use of mineral manures may obviously be either direct or indirect, according to the effect which they produce; for example, those substances which either alter the texture of the soil, or more especially such as supply saline matter to the plants themselves, may be said to be directly beneficial; whereas those which merely act as chemical agents in hastening the decomposition of the organic matter existing in the soil, can be said to be benefiting the plant in an *indirect* manner only. It will be impossible, however, to form any subdivision of this class of manures, upon the above fact, as many of them act in both ways, and moreover, the whole subject is as yet involved in so much doubt, that we should well deserve the imputation of rashness, were we to attempt any classification of these substances founded upon their mode of action. The more important purely mineral manures are *lime, its carbonate, or chalk, its sulphate or gypsum, marl, saltpetre, common salt, and kelp.*

Lime.—This is undoubtedly the most important of this class of manures, from which circumstance alone it well deserves to rank first in the list. Like all great benefits it has been most shamefully *abused*, but I think that it will be by no means difficult to prove that the fault lies entirely with the farmer who unfortunately is far too apt to follow example blindly, in place of really examining the *principle* upon which the *practice* is *founded*, and without which success is always precarious, and often absolutely impossible. In the subsequent remarks which we propose to make upon this class of manures, it will be necessary to enter much more fully into practical details than we have hitherto done, as the whole success or failure of these manures may be said to depend almost entirely upon their mode of application, and I may here premise that many of the *practical observations* which I shall have to make, are derived from the excellent, but now rare, pamphlet on manures by the justly celebrated Arthur Young.

The action of lime upon soil differs entirely according to the state in which it is used, namely, in the form of *true lime, hot lime*, or in the state of *mild lime*, as it is termed, in assuming which condition it has undergone some most important chemical changes which we shall mention presently.

The *chemical* properties of lime, and its *chemical* action upon organic matter, must, in the first instance, occupy our attention, in order that the subsequent remarks upon its use as a manure may be clear and intelligible. Lime is ranked by chemists among the *alkaline earths*, by which term is meant those earthy substances which exhibit characters similar in many respects to the true caustic alkalies, *potass, soda, &c.* it is always prepared by heating its native carbonate or limestone, to a temperature sufficiently high to drive off all the carbonic acid and water which it contains; so that were limestone composed of nothing else but *carbonate of lime* and water, pure lime alone would be left after burning; this, however, is never the case, as other substances, especially alumina, silica, iron, and often magnesia, occur mixed with the lime, but in good specimens these should be in very small quantities, as of course, I need hardly say that their presence diminishes the value of the specimen in direct proportion to their quantity. On this account, the proportion of lime contained in any new specimen of limestone should be accurately determined before applying it to agricultural purposes, more especially if there should be any reason for suspecting the presence of magnesia which we have so repeatedly said is injurious to vegetation, particularly in its caustic state. On this account we shall here give a few directions for the examination of limestone, which we trust will not be considered out of place. Let us suppose that the experimenter is not desirous of ascertaining the exact constitution of the limestone which he is about to examine, but merely wishes to discover whether it contains any considerable quantity of magnesia, alumina, or iron.

1. Let him take a small quantity of the sample to be analyzed, say 100 grains, and dissolve it in one ounce of strong muriatic acid (spirit of salt) mixed previously with about 2 ounces of pure water; when the effervesence (owing to the escape of carbonic acid) has entirely ceased, if any thing is left undissolved it must be separated from the solution, by filtration through white blotting paper, and the insoluble matter when dried and weighed may be noted down as *silica.*

2. The operator must next add to the filtered fluid successive portions of *strong ammonia (hartshorn)* until the liquid smells of this substance; any thing which is thrown down during this operation must be likewise separated by filtration; this will consist of *alumina* and *iron*, the proportion of the latter being judged by the darkness of the colour (*pure alumina* being white.)

3. The next step is to add to the fluid a solution of *oxalate of ammonia* (this should be prepared by a druggist) as long as any precipitate appears; this is the lime in combination with the oxalic acid.

4. Lastly, having again filtered the solution, add a small quantity of *carbonate of soda* (common soda) dissolved in water; if the former parts of the process have been performed carefully, no precipitate whatever will now appear, unless *magnesia* is present, so that the quantity of this substance may be judged by the proportion of this precipitate.

Difficult as this process may appear to those who have never performed any chemical analysis, still a very little practice will make it quite familiar, and it is the only method by which the presence of magnesia can be detected with unvarying certainty; at least without making use of chemical tests, which cannot be easily purchased, and are very troublesome to prepare. Should any one wish to render himself expert at the above operation, I should recommend his taking some specimens of limestone, and repeating the process several times, until he arrives at the same results by each experiment. If the quantity of lime is wished, the precipitate of No. 3 must be carefully collected, dried, and weighed; and then, every 100 grains will denote 34 grains of pure lime, or 61 grains of carbonate of lime in the original specimen.

Whenever lime, in its pure or *hot* state, is exposed to the air, it has a very great tendency to return to the original form of carbonate; in undergoing which change, it first absorbs a large quantity of water; and then assumes the form of slaked lime, or, according to chemical nomenclature, has become a *hydrate;* this hydrate, in its turn, rapidly absorbs carbonic acid from the air, and thus, in no long period, the burnt lime returns to its original condition, with the only difference, that whereas it was formerly in large stony masses, it is now in the state of a fine powder. When the lime is completely slaked, and *partially* carbonated, it forms the substance termed *mild* lime, by farmers.

Of these three conditions of lime, namely, the *hot*, the *mild*, and the true *carbonate*, the first is possessed of by far the most energetic powers. The true carbonate of lime, in fact, differs completely in its action from the others. We must, therefore, of necessity, treat of each separately.

Hot Lime.—When any organic matter is mixed with hot lime, it undergoes putrefaction with much greater rapidity than when left to itself. The exact cause of this is not well known; but the immediate *changes* which the various substances undergo, especially in the case of vegetable matter, have been pretty accurately examined. Thus, for example, it has been proved,*first*, that *woody fibre, gum, sugar*, and many other vegetable matters, are converted into *humic acid*, with more or less rapidity, when kept in contact with hot lime, or any other chemical substance which possesses strong alkaline properties. *Secondly*, that this *humic acid*, when formed, unites with the lime, and generates a compound which is not very soluble in water, but is easily diffused through it. And, *lastly*, it has been proved, that a very little lime is required to produce this compound, with a large quantity of humic acid. For example, 28 grains of pure lime are capable of combining with no less than 318½ grains of this acid; so that the lime in this compound amounts to little more than eight per cent.

To apply these facts, therefore, we may remark, that there is very little doubt, that changes similar to those above mentioned take place, when hot lime is applied to soil; or, still more so in the case of lime composts. At the same time, it is exceedingly probable, that during the production of *humate of lime** (the compound of lime and humic acid above mentioned,) other compounds are formed, many of which are very possibly soluble in water; at least if we may judge by the appearance presented by vegetable matter, after it has been long exposed to the action of this or any other alkaline matter. From these remarks it would appear, that the most important object to be gained by the application of hot lime, is the decomposition of *woody fibre*, and the consequent formation of *humate of lime*, and various soluble matters.

Mild lime does not act by any means so powerfully as the preceding compound; in fact, it appears to have no effect whatever upon woody fibre. On the other hand, however, it is capable of uniting with the humic acid existing in the soil, precisely in the same manner as hot lime; on which account, Sir Humphrey Davy remarks, that mild lime is useful in preventing the too rapid decomposition of substances already dissolved; the truth of which is evident, when we call to mind the well established fact, namely, that organic substances, which of themselves are extremely liable to decomposition, may be rendered much more permanent, nay, often perfectly so, by entering into *chemical combination* with any *inorganic substance*. Pure carbonate of lime will be treated of under the head of chalk.

So much for the pure chemistry of this most important manure. We must, however, now proceed to what the majority of our readers will consider as by far the most interesting part of the subject, namely, the practical deductions to be drawn from the above remarks; or, in other words, the manner in which practice is to be guided by the principles above laid down.

First.—It is perfectly clear, that *hot lime* will be useful in all cases where there is an excess of undecomposed vegetable fibre, as in peat-soils, moors, heaths, &c. in fact, in all places where the natural growth has not been interfered with for a great number of years; from which it follows, that hot lime will be a peculiarly useful application to old grass, which has lost heart from age, particularly if it is, at the same time, broken up for tillage.

Secondly.—Sir Humphrey Davy has proved, that hot lime, whether solid or dissolved, is injurious to growing plants.—For example, he states, that he has frequently killed grass by watering it with lime water. From this fact, therefore, it follows, that *hot lime* must be an extremely useful application, when it is desired to free land of its spontaneous growth; as for instance, in places overgrown with weeds.

Thirdly.—Hot lime is extremely useful in purifying (if we may be allowed the expression) the original herbage of moors, and other *uncultivated* grounds. The mode in which this is effected being somewhat interesting, we shall here say a few words upon the subject. It is generally allowed, that the finer grasses, &c. require richer food than those which are less valuable; and also, that the same remark holds good, the lower we descend in the scale of vegetables: namely, that the lower the plant is, the more easily it is nourished by the contents of the *atmosphere;* and hence the less dependent it is upon the soil for its subsistence; the consequence of which is, that when, in the lapse of time, the soil of any spot becomes more and more exhausted, the most valuable and important grasses gradually die away, from the want of sufficient nourishment, and give place to those diminutive species, which so frequently constitute the herbage of the almost barren moors; these again, if moisture be present, give place, in their turn, to various mosses, &c. so that at last, unless the improving hand of man steps in to avert the doom, the spot will return to a state unfit for the support of any living plant, with the exception of those which derive most, if not all, their nourishment from the surrounding air. Should it be otherwise, how different the result! For instance, should *hot lime* be applied, from the looseness of their texture, this destroyer first attacks the mosses and all other useless plants, and thus converts them into useful manure, which, by being washed into the soil by genial showers, revives the seeds of those plants which grew there ages previously, and, in a comparatively short time, the lately unprofitable waste glows with the return of its pristine verdure. How beautifully many of my readers must have seen this exemplified, in the crops of white clover which so frequently appear, almost like magic, after the liming of some barren moor!

Fourthly.—*Mild lime* is a most useful application in all cases, where any of the above circumstances occur in *cultivated land.* For instance, if the lime is comparatively fresh, it is much safer to employ it in the mild form, when we desire to destroy weeds or other injurious plants, growing upon richly manured lands, which, from carelessness or other such cause, have been allowed to become foul; for, were the lime, in this instance, applied in its *caustic state*, although it would unquestionably kill the weeds, still, their destruction would be accompanied with a great unnecessary loss of manure.

Fifthly.—It sometimes occurs, more particularly in garden ground, that the crops become rank, from the existence of a superabundance of soluble manure, the evil effects of which can almost always be counteracted by a dressing of *mild lime*, which, by combining with the humic acid, renders a large quantity of the organic matter much less prone to decomposition, and likewise, at the same time, less soluble; *humate of lime*, as before remarked, being by no means very soluble in water. It may very probably be asked here, how can it be advantageous to apply lime in any case to soil, since it tends to render *soluble* matters *insoluble*, when it has all along been stated that the very reverse is the proper mode of preparing the food for plants? An answer to this question must, therefore, of course, be requisite. It must be observed, in the first place, that we have already stated that lime is useful chiefly in those cases where the organic matter is *insoluble*, because it causes the formation of *humate of lime* and different *soluble* matters; all we have to account for therefore is, how humate of lime comes to be a useful manure? It may be remembered that I stated in No. 2, of this series,* that humic acid was of itself "quite *insoluble* in water:" from the result, however, of some experiments published since that number was written, it appears that this statement is not strictly correct, for humic acid is *soluble* in water (more especially when newly formed) except under particular circumstances, so that it is extremely probable that the humic acid derived from the slow decomposition of humate of lime, will, at the moment of its liberation, be capable of dissolving in water, and thus of course become a useful manure. We shall now conclude our remarks upon lime with a few important cautions to be attended to in its application.

Mr. Arthur Young remarks, that the best directions for applying lime are those given by Mr. Craike of Arbigland, who advises, that the whole quantity of lime that the farmer intends to apply to any field of moderate size, should be carted out, and laid together in a heap, at some spot where water can be obtained with the greatest facility. The whole is next to be thoroughly slaked; and *immediately* after it has cooled, which will take place in a day or two, the lime is to be recarted and spread over the surface of the land as equally as possible. Mr. Craike further remarks, that the more common method of laying down the lime in small heaps all over the field, and allowing it to slake by rain, is *very erroneous;* for in this instance it is very liable to get too much rain, which, in place of merely slaking it, and thus reducing it to a fine powder, converts it into "running mortar," in which condition "it will neither spread easily, nor mix with the soil." On the same principle Mr. Wight observes, that both the lime and the soil should be perfectly dry at the time of application. The truth of these remarks could have been predicted by scientific examination alone, and it is at all times pleasing to discover that the *results* of successful practice directly correspond with the *indications* of true theory. For example, there are many scientific objections to be made to the plan of laying the lime in small heaps all over the field in order to be slaked by the rain, in addition to the evident one, mentioned by Mr. Craike, namely, the formation of "running mortar." These are, 1st, that it exposes a far greater surface for the absorption of carbonic acid, which, as is evident from the remarks already made upon this subject, diminishes materially the effect of the lime. 2d, It must necessarily be exposed for a much greater length of time, and consequently will most probably be entirely converted into *carbonate of lime;* or it must be spread upon the land during wet weather, which will of course render it far more difficult to incorporate properly with the soil. And lastly, its being slaked by rain-water is directly injurious, as it has been proved that there is a greater quantity of carbonic acid present in the air, during dull than in bright weather, which gas will of course be absorbed by the rain, and thus carried to the lime, so as to increase still more the chances of its becoming carbonated. On the other hand, however, it is evident that all these objections may be obviated by adopting the simple, and if we look to the result, the much more economical method proposed by Mr. Craike.

As to the period at which the lime should be applied, this must depend so much upon peculiar circumstances affecting each farmer differently, as convenience, leisure, &c. that it is impossible to fix the time so as to suit all persons. When, however, a choice can be made, summer is by far the best season according to Mr. Young, the reason of which is obviously because it is the driest period of the year, and likewise, when hot lime is used to destroy weeds, they are generally in their greatest vigor at that time, and consequently are capable of being destroyed more effectually.

The quantity of lime to be used is likewise a subject of considerable importance, but nevertheless is one which is apt to be far too much neglected; upon this subject Mr. A. Young is most explicit. "In common cases," says he, "the quantity should be guided by a *chemical analysis of the soil;*" and, beyond doubt, this is the only sure way of applying it with success. What, for instance, can be more absurd, than for a farmer to go on applying lime to his land, time after time, when perhaps his soil is already loaded with calcareous matter? It is a well established fact, that an excess of any of the earthy ingredients of soil exerts a most important influence over the plants which grow there: this is remarkably the case with the natural productions of all soils. To such an extent, in fact, does this hold true, that a good botanist will tell with great accuracy the chemical nature of the soil, by the plants which he finds growing upon it. If this, therefore, takes place naturally, where seeds of all kinds must be be constantly deposited on every species of soil; if, I repeat, *nature* thus arranges the plants according to the constitution of the soil, shall we deny that they have any effect upon cultivated plants? Shall we presume to say that we can grow all kinds of plants equally upon every variety of soil? most assuredly not. How, then, can that farmer expect to be successful, who, by constantly adding lime to soil already *calcareous*, at length increases this substance to such a degree that it is unfit for the support of any plants, except those which naturally prefer a soil of this description? That the above statement is not a mere *theoretical* objection, is most distinctly proved by many facts. Who, for example, does not know that wheat is an unprofitable crop upon light soils? Or, again, who would attempt to cultivate turnips upon strong clay? *Chemical analysis*, likewise, of the plants themselves, prove most distinctly the influence which the earthy constituents of soil exert over the saline composition of the ashes of these plants. Thus M. Saussure found, that 100 parts of the ashes of common fir contained 43 parts of carbonate of lime when grown on a limestone hill, whereas the same quantity contained only 29 parts when grown on granite; and again, the ashes of the leaves of the *Rhododendron ferrugineum* grown upon limestone contained 43½ per cent of chalk, whereas it yielded 16⅔ per cent only of that substance when cultivated upon a granite soil. There can be no doubt, moreover, that the proportion of the different constituents of the ashes of plants have the greatest influence upon the vigor and productiveness of the plant itself, and I have no hesitation in saying that the culture of plants (more especially the *garden culture of exotics*) will never be brought to any thing like perfection until they have each and all been submitted to *chemical* examination; the proportion of all their saline constituents accurately determined; and the nature of the soil for each chosen upon these grounds. I leave it to those interested in such matters to decide, whether it would not be worth their while to take the requisite steps for the accomplishment of such an undertaking.

On the other hand, however, a very large quantity of calcareous matter may naturally exist in soil, without rendering it unfit for the purposes of cultivation; for instance, it is stated by Mr. Cuthbert Johnson, in the "British Farmers' Magazine" for April 1837, that "the richest soils, on the banks of the Parnel, in Somersetshire, contain more than seventy per cent of chalk!" But we are all well aware that there are many peculiarities in the cropping of calcareous soils which must be attended to in order to insure success. Almost all soils, however, contain more or less of this substance, and it is remarked by Professor Low, that it "generally, though not always, exists in larger quantities in the better, than in the inferior soils." None of these remarks, nevertheless, by any means favor the employment of lime upon calcareous soil, in addition to which the plea of not being able to succeed without it, will be shewn to be untenable, when we are treating of the "Economy of Manure;" consequently we may rest assured that Mr. Young's remark is perfectly true, namely, that the quantity of lime must be judged by a *chemical analysis* of the soil.

---

* I have continued to denominate this acid, humic acid, although I find that, latterly, especially in chemical works, the term *ulmic acid* has been substituted for it. I trust, however, that this will cause no confusion, as the difference is in the name only.

* No. XLII. p. 241.

Lastly, the farmer must always bear in mind that neither hot nor mild lime can act as a manure until it has become converted into *carbonate* or *humate*, and consequently that the fertilizing effect of these substances are produced *at the expense of the organic matter previously existing in the soil;* so that although lime is directly useful by calling into activity otherwise inert matter, nevertheless it undoubtedly *exhausts* the soil by so doing, and this of course should make the farmer cautious about repeating it too frequently; and he must be particularly careful lest he mistake the dimunition of the productive power of soil, caused by the too frequent application of lime, for a proof that more lime is required, as in this way there is no doubt that many agriculturists have as it were *poisoned* their fields, by the very means by which they had hoped to effect a cure. The two apparently opposite effects of lime must also be born in mind, namely, that although it *increases* the solubility of *inert* vegetable matter, still it renders much *less soluble* those parts of the organic constituents of soil which have already become capable of solution.

Carbonate of Lime or Chalk.—This differs from limestone merely in its being of a much softer texture, and hence capable of being broken down with greater facility. In its action it differs entirely from the last substance; thus it has no effect whatever upon inert vegetable fibre, and I should very much doubt whether it is in all cases capable of uniting with humic acid, so as to render the soluble parts of the manure less prone to decomposition. Its action, however, is nevertheless most beneficial; for example; it tends greatly to alter the texture of the soil to which it is applied, and possesses likewise the very useful property of being retentive of water, without at the same time becoming adhesive; consequently, it can be used with the greatest advantage both to clays and sands, under certain circumstances. If, for example, you wish to open the texture of a clay, and render it more friable, but at the same time are not desirous of diminishing to any considerable extent its retentive powers, you cannot do better than apply chalk; and again, if you are anxious to increase the absorbent power of a sand without at the same time adding to its tenacity, a good dressing of chalk will in most cases produce the desired effect. The advantages of chalk as a top dressing to meadows is far too well known to require any notice here. It is, however, by no means easy to understand its mode of action, except there were an actual want of that substance in the land previous to its application; in which case, of course, the good effects could be explained upon the principle adhered to throughout all these observations upon Agricultural Chemistry, namely, that we can never expect to be successful in the cultivation of any plant, unless we supply it with all the ingredients, whether *organic* or *mineral*, which it contains when growing in a state of nature, upon a soil of its own choosing, if we may so express it; the importance of which remark, in reference to chalk, will at once appear, when it is considered that scarcely a plant exists which does not contain more or less of this substance. As the total want of chalk, however, is a very rare occurrence in soil, we must look to other modes of action, in order to explain the frequent beneficial effects which result from top-dressing grass with this substance; and I may here premise, that this subject is one upon which extremely little is known at present, and consequently we can do little more than make a few conjectures regarding the various possible modes of action; these, nevertheless, may be of use in directing the attention of those who should wish to examine the subject to certain points which they might otherwise be apt to overlook.

It will be remembered, that, in enumerating the various constituents of soil, in the first number of this series, I had occasion to mention iron as a constant ingredient of soil, although I at the same time observed that it seldom occurred in any considerable quantity in fertile soils. All my agricultural readers must be well acquainted with the fact, that, when this substance, by any means, becomes soluble in water, it is most prejudicial to vegetation of all kinds. Now, it is extremely probable that this fact will be found of great consequence in explaining some cases, at least, in which the beneficial effects of chalk have been observed. There is no practice more common (and I by no means wish to censure it) than the top-dressing of old pasture-land with farm-yard dung at the interval of a certain number of years; but all animal matters contain more or less sulphur, so that whenever these substances undergo decomposition, *sulphuretted hydrogen* is always one of the products. Now, it is well known to chemists that when *sulphuretted hydrogen* and *oxide of iron* (the form in which iron exists in the soil) come into contact, a mutual decomposition takes place, and there results *water*, and *sulphuret* of *iron*. This compound, however, is of itself *insoluble*, so that were no further change to take place, no harm whatever would accrue from this chemical combination; but unfortunately this is not the case, for the *sulphuret of iron*, by exposure to air, gradually undergoes an entire change, and is at length converted into a very soluble substance, namely, *sulphate of iron, or common copperas, or green vitriol* as it is termed. In this manner, we perceive that, in the progress of time, the application of farm-yard dung or any other *animal* manures to soils rich in iron, renders this substance *soluble*, in which state, as before mentioned, it is exceedingly prejudicial to vegetables. How, then, is this to be remedied? or how is it that this does not always take place? In soils rich in calcareous matter, although the change does take place, it is of no consequence whatever, for as soon as the *soluble* sulphate of iron is formed, it is acted upon by the carbonate of lime, and the results are *sulphate of lime* or *gypsum*, and *oxide of iron*, or in other words the iron is restored to its original *inoffensive* state; but where there is not sufficient lime in the soil, as for instance, where there is a large quantity of iron, this substance must be added; the form of chalk being of course preferable, as in this case no action upon the vegetable fibre of the soil will be required. When such intricate and important chemical changes are constantly going on in the soil, and when it is considered that, unless the remedy is at hand, the very *food* given to the plants carries *poison* with it, and consequently, that unless checked by proper means many valuable pastures would be rendered useless. Who will deny the importance of *chemistry* to the farmer? or who will dare to say that practice *alone* acts more *certainly*, though more slowly than when aided by *science?* Surely it must be evident to every thinking mind, that the practice of agriculture would be upon a much surer basis, were all its votaries acquainted with the principles upon which their art was founded. And if so, why is there such an apathy evinced by the supporters of this all-important art to the advancement and cultivation of *its science?* To be sure, a slight stir of late has been made among some of the leading societies connected with agriculture, but with what effect *who can tell?* and the reason of this is obvious,—the majority of the agricultural population are by no means devoted to reading, and consequently, though all the agricultural societies in Great Britain were to publish upon the subject, it would be long ere the farmers became acquainted with the fact. To do good they must have the advantages of the science *laid before them practically*, and this can be done only by the establishment of experimental farms under the direct superintendence of both a *practical* and a *scientific* farmer; or by the formation of agricultural schools, in which the youth intended to follow such pursuits shall be properly instructed in the principles which should guide them in the prosecution of their business. That some such decided step will be immediately taken by those capable of rendering its success a comparative certainty, is the most ardent wish of the author of these papers.

Marl.—This substance naturally comes under our consideration here, as it is generally allowed that marls are valuable in direct proportion to the quantity of calcareous matter which they contain. The marls most common in England are the clay, stone and shell marls; they are in general composed, similar to soil, of silica, alumina, carbonate of lime, and frequently oxide of iron, so that, in fact, they might be compared to calcareous soils. The carbonate of lime varies from 20 to 80 per cent. One of the best clay marls quoted by Arthur Young was composed of carbonate of lime 40 per cent, alumina 40, silica 8 or 10, and a distinct trace of iron. The action of this substance is, of course, in the main similar to chalk, but the clay marls are likewise very beneficial in giving tenacity to loose sands. There are two or three points to be borne in mind with reference to the application of this substance, which we shall here mention.

First, And this is of great importance, marls are often very injurious when applied to the soil immediately after they are dug; whereas this effect is completely prevented by allowing them to remain exposed to the air for a certain length of time, as, for example, by placing them in a heap and turning it frequently. I have never been able to find any attempt to explain this very curious fact, and I candidly confess that I do not know how to account for it. The fact, however, is universally acknowledged, and that the only probable plan of discovering the cause of the injurious effect would be to subject specimens, wherein the evil was known to exist, to careful chemical analysis, and, in this manner, discover in what particular they differ from others which do not possess this injurious property. An investigation of this sort is, however, far too delicate to be performed by any person who does not possess a thorough knowledge of chemistry, and I should therefore recommend the proprietors of marl-pits of this description to employ a professional person to discover the cause of the injury, as in all probability such discovery would point out some means of cure, which would require much less time and trouble,—those invaluable commodities,—than the process by exposure above referred to.

Secondly, The farmer must always bear in mind that marl acts merely on account of the carbonate of lime it contains, unless it is added for the express purpose of altering the texture of the soil, as, for example, when applied to very light sands, in which case it will act beneficially, even although the land should not be in actual want of calcareous matter. In this instance, however, pure clay would answer as well, and be more advantageous, inasmuch as the whole quantity carried will be of value, whereas if marl were used, about one-third of the quantity would consist of chalk, which, in this instance, would be of no value. On the other hand, marl is of course far inferior to chalk or lime for clay land; this fact seems well known to farmers, as will be seen by the following rhymes, which occur in a paper upon peat, published by the Rev. Dr. Walker in the Transactions of the Highland Society for 1803. In speaking of the application of marl as a manure, he observes that the Lancashire farmer says,

> "If you marl *sand* you may buy *land*,
> "If you marl *moss* you shall have no *moss*,
> "If you marl *clay* you *throw away all*."

Lastly, When marl, or any other substance dug from below the surface of the ground, and used in large quantities, is applied, the farmer must always recollect that surface-soil alone contains organic matter, and that fresh subsoil has the power of combining *chemically* with a considerable quantity of soluble manure, and rendering it much less decomposable, so that, unless the soil is rich in manure at the time of application, the farmer must not expect to see any marked improvement immediately after he has applied the marl; nor should he condemn the practice even although the first crop should be somewhat inferior to those before the marl was used.

Gypsum, or sulphate of lime. This substance more properly belongs to a class of manures, which are at present very little known among farmers, but which I trust will soon attract that degree of attention that they undoubtedly merit; I mean those which the ingenious Mr. Grisenthwaite denominates *specific manures*, by which term is implied, that the substance in question does not act as organic manure, by supplying organized matter to the plant, nor as many mineral ones, by acting chemically upon the vegetable fibre of the soil; but owe their beneficial effects to their power of supplying the plants with certain *saline combinations* which are essential to their perfection, and are for the most part peculiar to the plant itself, or, in other words, belong to a few plants only. Upon this very interesting topic we have frequently had occasion to throw out a few hints, but have not hitherto made any express remarks, as we considered that they would be much more suited for this place. The subject being almost entirely new, is at present in a very imperfect state, and the subsequent remarks will serve merely to direct the farmer's attention to the point, and I sincerely hope they may be the means of inducing some one to follow out the work in the only way in which it can be achieved, namely, by *chemical analysis*.

It has been proved by chemical analysis, that many plants, probably all, contain some saline substance peculiar to themselves, and consequently of great importance to the welfare of the plant. These salts are frequently of a kind which by no means constantly occur in soil, as for example, *phosphate of lime, sulphate of lime, nitrate of potass, &c.* and, of course, the plants which require these cannot be expected to thrive under such circumstances, unless they are supplied artificially with the required substance. It comes, therefore, to be a point of the greatest consequence to the farmer, that a very careful analysis should be made of all the cultivated plants, in order that the exact constitution of the saline matter should be ascertained, and in this manner the farmer will be enabled, in many instances, to grow plants in situations which probably could never before be made to bear them profitably. For example, to apply this remark to the specific manure now under consideration. *Gypsum* has been the subject of several experiments, in order to ascertain its value as a manure, the results of which prove that it is often useful for *grasses*, and always valuable for *clover, saintfoin, lucern*, and analogous leguminous plants. Now these are the very plants whose saline matter contains abundance of sulphate of lime. Sir Humphrey Davy's remarks upon this subject are truly valuable. He says, for example, that most grasses, especially *meadow fox-tail, cocksfoot* and *fiorin*, contain gypsum; and he observes that the application of this manure would probably be of great value in restoring lands which have been exhausted by frequent *clover crops* and the like. The reason why this substance is not constantly required is, that most soils contain a little of it, but more especially because *all animal manures* have a certain proportion of this substance, and therefore, cultivated land seldom requires any to be added to it. On the other hand, however, it is well known that there are few crops so uncertain as the clover crop, and consequently it would be of great importance to ascertain how far this failure may depend upon the want of sulphate of lime, as, of course, that could be prevented with the greatest ease. There is one point to be attended to with reference to the use of gypsum, namely, that is is apt to fail in some cases where a farmer would least expect it, namely, in soils rich with *animal manures;* chemically, however, this is just what we should have been led to expect; because, during the decomposition of animal matters, *carbonate of ammonia* is produced, which reacts upon the *sulphate of lime*, and produces sulphate of ammonia and carbonate of lime, neither of which are capable of supplying the place of gypsum as a *specific manure*. It is stated that gypsum is particularly useful when it is intended to cut the crops green, as it makes the plants renew their shoots much more vigorously than they otherwise do.

Annual Address,

Before the Kentucky State Agricultural Society—delivered at the Capitol in Frankfort, January 14, 1839, on the dignity of the profession of agriculture, and the propriety of legislation for its improvement.

BY COL. C. S. TODD, OF SHELBY.

(Concluded.)

Agriculture constitutes the business of seven-eights of every civilized community, and is the ultimate source of all national power and wealth, commerce and manufactures being only subordinate results of this main spring. If it be conceded that it is the duty of the legislator to consult the good of the greatest possible number in the community, the transcendant claims of this class will not be questioned; and taking for granted that the condition of our agriculture admits of improvement, and that such improvement will lead to the receipt of greater revenue, there will be no difficulty in obtaining an assent to the proposition that the state is bound to elevate the standard of good farming. This high object has been effected in some of our sister states and in some portions of Europe, by the endowment of agricultural societies of Europe, by the endowment of agricultural societies and of agricultural professorships in colleges, to induce experiments and impart scientific knowledge in all the branches of farming. These measures have been adopted with the happiest results—those who originated them having concurred in the opinion of Sir John Herschel, the great astronomer, that "the arts cannot be perfected till their whole processes are laid open: they are the application of knowledge to a practical end; if this knowledge be experience, reasoned upon and brought under general principles, it is *scientific art*."

The advances made in agriculture by the Romans, so beautifully illustrated by their poets and orators, shared the fate of other improvements that were buried in the dark ages, and it was not until after the revival of letters that the present system of farming commenced in Flanders about 800 years ago; and although the soil was originally a barren white sand, it now yields twice as much as the lands in England. The practicability of *creating* soil is shown in the history of Flemish husbandry. They seem to want nothing but a space to work on, whatever was the quantity or the quality of the soil, they made it productive. It is their maxim, that "without manure there is no corn—without cattle there is no manure—and without grain crops or roots, cattle cannot be kept." The productiveness of their lands proceeded from six causes—small farms, manure, rotation of crops, clover and roots, cutting the forage and grinding the grain—and the farmers giving their personal attention to their farms: no lumbering, no fishing, no speculation, no hankering after office. If the personal digression be pardonable, I will refer in connexion with this subject, to an incident which occurred in my own history when entering upon the cultivation of the soil. In conversing with an experienced farmer, I was led to inquire as to the best mode of making corn. He told me that I must *keep my work horses fat*. I did not then perceive the comprehensive character of his counsel, but have long since realized that it implies every thing connected with good cultivation, although neither he nor I then knew that Cato, one of the most illustrious of the Romans, 2000 years ago, had announced that "the true secret of farming consists in *feeding well*."

The great Von Thaer first introduced into Prussia, under the auspices of the sagacious Frederic, the agricultural schools, which "connected the science with the practice of agriculture—which made gentlemen farmers, and farmers gentlemen—combining intellectual with physical power, and literature with labor." Frederic expended a million annually for these purposes, and said he considered it as *manure spread upon the ground.* In Paris a society has been formed which communicates with more than 200 local societies in France, receiving annually $100,000 from the public treasury. Agricultural colleges have been established at St. Petersburgh and Moscow, in Prussia, Bavaria, Hungary, Wurtemburg, Ireland, France, and in Scotland, who effected her late astonishing improvements by her skilful agriculturists reducing their practice to writing, thus establishing agriculture as a science. Fellenburg has a school in Switzerland with pupils from Switzerland, Germany, France, Spain, Portugal, North and South America. The Highland society in Scotland has appropriated 500 sovereigns as a premium for the first successful application of steam-power to the cultivation of the soil, and premiums for other objects to the amount of $15,000. The agricultural condition both of England and Scotland, has been advanced to its present prosperity by the lights of science applied to the cultivation of the soils. The tour of Sir Arthur Young, to the continent in 1788-9, for the purpose of looking into the countries there under the best system of farming, produced the first decided advances in England to her present agricultural maturity and the perfection to which the art has been brought in Scotland, is ascribed chiefly to the endowment of an agricultural Board, through the influence and exertions of Sir John Sinclair.

Agricultural societies are not now to be regarded as experiments: they are the peculiar privileges of modern times. Before they were formed, in New-England and New-York, 10 bushels of rye, 20 of corn, 200 of potatoes and one ton of hay, was the average crop. Since premiums were offered, claims have been presented for having raised from 40 to 50 bushels of rye, from 115 to 122 or corn, from 400 to 500 of potatoes and from 3 to 4 tons of hay. Massachusetts gives a bounty equal to the cost of manufacture upon the growth of silk, and upon manufacturing beets into sugar. After experiencing the benefit of a former appropriation she has voted to continue it. Maine, Vermont, Connecticut, New-Jersey and Pennsylvania have also granted a bounty upon the growth of silk. Will these examples and these results be lost upon us? Will not the State as well as our farmers profit by the experience acquired in other States of the value derived from legislative encouragement, and ought not an agricultural survey to follow the geological reconnoisance now in progress, which will develop the intimate relation between the minerals that the earth covers and the true method of cultivating its surface?

An improved state of husbandry in Kentucky, and the system of improved roads and navigation, will act with reciprocal benefit upon each other; the roads and rivers will enhance the price of agricultural products by the greater facilities afforded in conveying them to market, and thus increase the revenue from tolls; while the increase in the products of the soil will not only add to the tolls but will furnish an increased revenue, both from the value of the increased products and the increased value of the lands. For the want of any accurate statistical tables shewing the agricultural product of the whole State, it is impossible even to approximate to a correct estimate, but it is palpably evident that 10 per cent upon the amount would yield a large revenue, and will any sensible farmer doubt that our modes of cultivation may not be improved so as to add 20 or 50 per cent to the wealth of the State? And if, according to Pliny, Egypt with only 6000 square miles, at one time contained a population of 20,000,000 by reason of the immense fertility superinduced by the government leading canals from the Nile, what may not be the future destiny of Kentucky, with more than six times the territory, when her resources shall be developed and invigorated by the same beneficent policy? Of the value of canals, or slack water navigation, which is more beneficial, upon the agricultural interests of a country, a striking illustration is given by Count Chaptal, a Peer of France, distinguished for his attainments in agricultural chemistry and his experience as a practical farmer, who traversing a barren part of Flanders, accompanying Napoleon, the latter expressed his surprise at a meeting of the council of the department, that so great a tract of land remained uncultivated in so illustrious a nation. The answer was, "If your Majesty will order a canal to be made through this district, we pledge ourselves that in five years it will all be converted into fertile fields." The canal was ordered to be made without delay, and in less time than they promised, "not an unproductive spot remained." This was effected by means of the easy transportation upon the canal, of the manure from the rich districts.

The chief magistrate, alluding in his last annual message to the deep interest which the State ought to cherish in the cause of internal improvement, uses the emphatic language that "Kentucky cannot stand still." A noble sentiment! worthy indeed of a patriot, and which may be illustrated by reference to many pround periods in the history of the State. The soldiers of the revolution, who were the pioneers in planting the standard of liberty, law and civilization on this once "dark and bloody ground," rescuing it from the savage and from the forest, "did not stand still." In the second war for independence waged in defence of commercial interests and of sailor's rights, of which she was not personally the victim, Kentucky "did not stand still;" her valor and her patriotism having signalized every field of blood from the shores of the lakes to the banks of the Mississippi.—"Kentucky did not stand still" in the cause of human freedom, whether she supposed that standard was unfurled among the children of the sun in the south, or on the classic shores of Greece; and now in this age of improvement, she stands ready to take her place among her enlightened sisters of the confederacy, by entering upon a noble career in reference to the high interest which the Governor elucidates with so much ability. But may we not hope that if the day has not already dawned, it is rapidly approaching, when she "will not stand still" in efforts to advance the great cause of agriculture? All the motives which may be sudposed to have influence in causing her march to be "*onward*" in relation to the cause of internal improvements, apply with equal force to the encouragement of her agricultural interests; for if the appropriation of seven millions of dollars to the construction of paved rail-roads and slack water navigation, be justly predicated on the assumption that it will increase the wealth and consequently the revenue of the State, there can be no conceivable reason why an improved condition of agriculture, superinduced by the application of science to art, shall not demand of the legislative councils some display of the public bounty. The selfish as well as the more elevated motives which ought to prompt the farmer to adopt such methods and to seek such information as science imparts to the cultivation of the soil, whereby an increased profit may attend his labors, address themselves with undiminished force to the legislative councils; for if, as in the case of Scotland and the New-England States, the endowment of agricultural societies and professors, and the authorizing of agricultural surveys, should lead to a *fourfold* increase in the productions of the soil, the bounty granted by the state would be more than repaid in an increased revenue. But this subject is too transcendent in its beneficial influences, to be estimated merely by the dollars it would yield to the treasury of the state or of individuals. An improved condition of agriculture carries with it a train of blessings which money cannot purchase, in an increased intelligence and a higher toned morality in the mass of the people. In proportion as science shall shed its rays upon the path of the farmer; and in proportion as "mind, the grand source of intellectual pleasure, the master power which abridges labor," shall be exerted on the pursuits of agriculture, the character and dignity of the profession will be advanced, the sources of national strength will be developed, and the indications of moral improvement will be visible in the public countenance. If it be contended that the plans which are in progress for the improvement of the soil partake of the character of experiments, and that therefore the legislature should pause in granting aid, we may derive an instructive lesson from the history of the growth of cotton and of sugar. Fifty years ago it was not known that cotton would grow in the United States, but the experiment received the fostering care of government, and from only 200,000 pounds being exported in 1791, more than *four hundred millions* are exported at the present time. Then, its production was limited to one state—now, it is the staple of seven, regulating by its price nearly every other production, and supplying, in addition to our own great and increasing demand, two-thirds of all that is used in foreign climes. Indeed, the culture and manufacture of cotton have now become the support of more than ten millions of the human race in Europe and America, and of more than fifty millions in Asia and Africa. A more recent experiment in Maine and Massachusetts, has served to exhibit the value of legislative encouragement in aid of agriculture effort. Maine granted a bounty to the growth of wheat of $150,000, and a large bounty was given by Massachusetts upon the same article, at a period when her consumption of imported flour amounted to $7,000,000. It is now ascertained that both these states will be able to export flour—the policy having originated from the supposed fact that their inhospitable soil and climate would not produce grain; but intelligent, scientific agriculturists, men whom the ignorant stigmatize as "*book farmers*," acted upon a different opinion, and its truth has been demonstrated in the fact that wheat has been successfully grown in Maine, further north than Massachusetts, thus presenting another instance of the soundness of the maxim that experiment is the mother of improvement and improvement is the true source of wealth.

I cannot exaggerate to myself the importance which a free people should attach to agricultural periodicals and to agricultural education. All the valuable improvements in husbandry have been the result of scientific effort and of the wide spread dissemination of the opinion which the writings of the most eminent Romans inculcated, that the cultivation of the soil and of elegant letters were not incompatible pursuits. By the application of the physical sciences, the wonderful creation of modern times, agriculture has become not merely a mechanical employment, but a science founded upon the process of induction from ascertained facts, and if a medical institute be entitled to legislative regard, the claims to a bounty for an agricultural education are equally imposing, science being alike beneficial to both—the one to preserve and prolong life, the other to nourish it and multiply its comforts. The public mind should be excited to the tone which prevailed in ancient Sparta, of regarding the children of the republic as the property of the republic, as the materials of our temple of freedom, erected upon the principle of teaching the hands to *work* and the mind to *think.* In reference to this vital interest, the late De Witt Clinton indulged in a prophecy in his last message to the legislature of New-York, which the experience of the schools in Prussia and other German states has since fulfilled. He said, that "by a proper system of education and correct modes of teaching, our children might become familiar with the physical sciences, botany, mineralogy, the various classes of animals, chemistry, natural philosophy, astronomy, the fundamental principles of agriculture and political economy, and much of history and biography."

The endowment of agricultural schools and the circulation of agricultural journals is rendered the more necessary from a consideration of the peculiar habits and modes of thinking prevalent among our farmers. As a class of people they have little intercourse with each other; they do not preserve the result of their experiments in books, like mechanics and manufacturers; they have rarely held conventions to concentrate into a focus the lights of the day, to be thence imparted through the press to the remotest ends of the republic; they entertain an unworthy prejudice towards the attainments of book farming; they profess to be too old to seek or to receive information upon the great business of their lives, and therefore we must look to the means which shall enlighten the rising generation for any hope of future high attainments in agricultural knowledge. In designating the source of these unpropitious notions among our farmers, we shall perceive at once the pernicious influence of their reluctance to read agricultural journals; and as if they had designed to set at nought all the maxims of common prudence, we find them encouraging and sustaining nearly one thousand political papers, whilst not more than twenty papers devoted to agriculture are supported by a class whose numbers and importance are in the inverse ratio of their distinctive journals.—The farmer is content to meet his neighbor at the court yard, at the muster, at the election, and occasionally at the fireside in the winter, to converse about his farm and its products, and sometimes about the reason of different modes of cultivation, but he will reject a newspaper devoted to agriculture, which conveys to him the concentrated experience of all the intelligent and practical farmers who have lived in every country and in every age, and cannot be persuaded to realize that in persuing the pages of the N. Y. Cultivator, the Genesee Farmer, the Farmer's Cabinet, of Penn., the Farmer's Register of Va., the Buckeye Ploughboy, of O., and the Maine Farmer, the N. E. Farmer, the Farmer and Gardener of Balt., and the Franklin Farmer, he is conversing at his leisure with those in every age who have made farming both a science and a business. In view then of these facts, who can estimate the vast amount of every species of improvement in cultivation, the results of individual exertion for ages, that has been lost for the want of convenient methods of communication; or who would now attempt to calculate the addition that has been made to our stock of agricultural knowledge and wealth by the publications which are now diffusing their light all over the country?

As an evidence of the deep necessity for the adoption of some stimulating measures in relation to our agricultural condition, we have only to advert to the crop which is annually produced in Kentucky, not exceeding upon an average 35 bushels of corn, 12 of small grain, 500 lbs. of hemp and one ton of hay to the acre; and whilst the Atlantic States present the humiliating spectacle of importing hay and oats from Scotland, eggs from France, potatoes from Ireland and Germany, and bread stuffs from every country in Europe, Kentucky imports clover and timothy seed from Wheeling and Ohio, and seed Irish potatoes from Pittsburg. How few among us understand the amount which an acre *perfectly cultivated*, will produce. How few understand the secret of producing the greatest result without deterioration to the soil; the object being not merely to obtain the greatest crops for a few years, but the largest annual returns compatible with the increasing value of the soil. And how few now realize the startling fact that a farmer from Flanders would support his family by the cultivation of the fence corners now in weeds upon any of the large farms in Kentucky.

These reflections, gentlemen, are submitted to you in the hope that we may all begin to learn something of our duty, and I shall be more than compensated if they shall have the auspicious effect of leading my brother farmers to *think*, and the legislative authority to *act* in relation to the great interest upon the prosperity of which every other depends; for the sentiment of Dean Swift is not less true now than when first published, "that whoever could make two ears of corn or two blades of grass to grow upon a spot of ground where only one grew before, would deserve better of mankind and do more essential service to his country, than the whole race of politicians together."

Allow me then, in conclusion, to appeal to your pride of character, to your patriotic feelings and to your patriotic energies, by addressing to you the language once applied to our profession by that ripe scholar and able financier, who has since won golden opinions for himself as President of the Bank of the United States. "In this nation, agriculture is probably destined to attain its highest honors. The pure and splendid institutions of this people have embodied the brightest dreams of those high spirits who, in other times and in other lands, have lamented or struggled against oppression; they have realized the fine conceptions which speculative men have imagined, which wise men have planned, or brave men vainly perished in attempting to establish." * * "The American farmer is the exclusive, absolute, uncontrolled proprietor of the soil. His tenure is not from government. The government derives its power from him. There is above him nothing but God and the laws; no hereditary authority usurping the distinctions of personal genius; no established church spreading its dark shadow between him and and heaven. But his character assumes a loftier interest by its influence over the public liberty. It may not be foretold to what dangers this country is destined, when its swelling population, its expanding territory, its daily complicating interests, shall awaken the latent passions of men, and reveal the vulnerable points of our institutions. But whenever these perils come, its most steadfast security, its unfailing reliance, will be on that column of landed proprietors—the men of the soil and of the country, standing aloof from the passions which agitate denser communities, well educated, brave, and independent—the friends of the government without soliciting its favors, the advocates of the people without descending to flatter their passions; these men, rooted like their own forests, may yet interpose between the factions of the country, to heal, to defend and to save."

On the Preservation of the Fruits of the Earth by Drying.

[*From Chaptal's Chemistry Applied to Agriculture.*]

In all vegetable products, water exists in two different states, one part of it being found free, and the other in a state of true combination: the first portion, not being confined except by the covering of the vegetable, evaporates at the temperature of the atmosphere; the second is set free only at a temperature sufficiently high to decompose the substances containing it: the first, though foreign to the composition of the vegetable, enters into every part of it, dissolving some of its principles, serving as a vehicle for air and heat, and being converted by cold into ice; by these several properties it greatly facilitates decomposition: the second portion, from which no evil of the kind arises, is found combined and solidified in the plants, and its action is thus neutralized. Drying, then, consists in depriving the product to be preserved of the water contained in it in a free state, by heat; and from what has been observed above, it follows, that too great a degree of heat must not be applied, as, in consequence, the taste and the organization of the substance would be changed by a commencement of the decomposition of its constituent principles: the temperature should never be higher than from 35° to 45° of the centigrade. (= from 95° to 113° Fahrenheit.)

Drying can be performed either by the heat of the sun or in stove rooms. In the southern climates the heat of the sun is sufficiently powerful to dry the greater part of the fruits, and thus to preserve them unaltered: the drying is effected by exposing them to the rays of the sun upon hurdles or slates, where they will be protected from rain, dust, and injury from animals. Practice alone is sufficient to enable one to judge of the degree, to which each kind of fruit must be dried in order to its preservation.

When the outer skin or rind of the fruit is of a kind to prevent the water from passing off freely, incisions are made in the rind to faciliate its evaporation. In this manner are prepared most of the dried fruits, which form so considerable an article of commerce between the south and north.

Those fruits which contain much sugar, as prunes, figs, musk grapes, &c. may be prepared in the above manner, and preserve nearly all their qualities, but the acid fruits acquire a disagreeable sharp taste by the concentration of the juices; some of them, however, may be kept advantageously in this way.

In the hottest countries the process of drying is often commenced by subjecting the fruits to the heat of an oven, after which they are exposed to the sun; some kinds of fruits are thrown into a weak ley, till their surface becomes wrinkled, when they are taken out, carefully washed in cold water, and afterwards dried in the sun: cherries particularly are treated in this manner. When the heat of the sun is not sufficiently great to evaporate all the water contained in the pulp of large, fleshy fruits, they may be cut in pieces and then dried: in this manner apples and pears are prepared for keeping.*

But this method is neither speedy nor economical enough for such preparations as have but little value in commerce, and which can never supply, for domestic purposes, the place of those whole fruits, which may be easily preserved from one season to another: it is therefore customary to perform the drying either in stove rooms or ovens. In the first case, the fruits, after being cut, are placed upon hurdles arranged in rows in a chamber heated to 112°: in the second, the fruits are put into an oven, from which bread has just been drawn; this is repeated if the fruits be not sufficiently dried the first time.

Some of the fruits referred to above, may be dried without being cut: of this kind are the tender pears, which cannot be preserved fresh through the winter; such as the rousselet, the butter pear, the doyenné, the messire-jean, the martinsec, &c. These are first peeled, and then thrown into boiling water, after which they are put upon hurdles into an oven heated less than is required for bread; after an interval of three or four days the pears are again exposed to the same degree of heat, having been however first flattened between the palms of the hands, whence they have acquired the name of *pressed pears*.

Fruits prepared in either of the above ways are susceptible of fermentation upon being soaked in water, and they thus serve to make a cheap and useful drink.

In those countries where these fruits abound, the drying of them is commenced about the first of August, and those are made use of, which then fall from the trees; in autumn, when the harvest is gathered in, the soundest and finest fruits are carefully selected to be used fresh, whilst the rest are dried and preserved in a place free from moisture, to be employed in making drinks. I shall in another chapter speak of the processes by which this is effected.

The herbage, which serves as food for domestic animals, can be preserved only by drying, and this in all countries is practised at the time of cutting. Fodder, which is imprudently stacked up whilst still damp, ferments, and the heat thus produced is sufficient to change the quality, produce mouldiness, and is sometimes even great enough to set the whole on fire.

There are some fruits, which may, by a few slight precautions, be preserved throughout the year. The first of these precautions is, that of depriving their surface of all moisture before putting them up; and the second consists in keeping them in dry places, where the temperature will constantly be between 50° and 54° Fahrenheit: the third, in separating the fruits, so that they shall not come in contact; I have seen apples preserved in this manner eighteen months. It is necessary to be particular in selecting fruit for preservation; that only should be taken which is perfectly sound.

Wood and other portions of vegetables, and various animal substances are likewise preserved by drying; this process increases their hardness and renders them less accessible to the action of air, insects, and other destructive agents.

The process of drying is not confined to preserving fruits from decomposition: it furnishes the means of securing their juices unaltered for the formation of extracts of them.

When the juices of plants can be extracted by pressure alone, it is only necessary to evaporate these juices at a due degree of heat and in suitable vessels, till, being deprived of all the water which retained them in a liquid state, they are reduced to dryness. Evaporation, if continued for a long time at the temperature of boiling water, changes these juices a little; the albumen, which is contained more or less abundantly in all sweet fruits, is coagulated, and after this they are no longer susceptible of undergoing the vinous fermentation.

The must of grapes, operated upon in this manner, furnishes an extract called *raisiné*, which is an article of food both wholesome and agreeable, and which, when soaked in water, decays without producing alcohol. The fermentative power of this substance may however be restored by mixing with it a little of the yeast of beer. as this repairs the loss, which the juices had sustained by heat during evaporation.

All the juices obtained from sweet fruits may be converted into extracts and thus furnish agreeable food: the quality of the extract varies according to the quantity of sugar contained in the fruit, and the care taken in the operation: when the juices are several times clarified, and evaporation carried on in a water bath, care being taken to stir the liquid to prevent its adhering to the sides, the colour and taste of the extract or jelly obtained is far superior to that procured without employing these precautions.

The sweetest fruits, however, even the well ripened grapes of the south, contain a portion of acid, which, when concentrated by evaporation, acts upon the copper boilers in which the operation is carried on, so as to form an acetate of copper: this by producing colics, would render the use of the extract dangerous, especially at the south, where the principal article of food for children is the *raisiné*. In order to obviate this serious evil, an ancient and generally followed custom is observed: as soon as the must of the grapes begins to boil in the coppers, a bunch of keys is thrown in, and allowed to remain till the operation is completed: these keys attract the copper and become covered with the precipitate thus formed; and nothing remains in the extract but the acetate of iron, which is not injurious.

I have observed that the juices of all succulent fruits might be converted into extracts, and thus preserved for use in the course of the year; but the greater part of these juices, when concentrated by evaporation, are so excessively acid as to be totally unfit for food, and they only form, when mixed with water, a very sour drink. In order to correct or conceal this acidity, these juices are boiled with an equal weight of sugar and thus made into sirups and jellies.

As it is of importance to be able to extract and preserve for domestic purposes, for pharmacy, and for the arts, certain vegetable products, which can be only very imperfectly obtained by mechanical pressure, recourse is had to other means; those liquids are made use of which will dissolve the wished for principles, and the solution is afterwards evaporated to dryness.

The fluid most generally employed for solutions is water; this dissolves the extractive matter; mucilage, sugar, and the greater part of the salts, and mixes with the mealy portions of plants; it may be applied cold or hot to the vegetables, or they may be boiled in it, according to the nature of the principle to be extracted; water will dissolve all that is soluble in them, and the extracts may be obtained from the solution by evaporation.

The resins, which are found so abundantly in some vegetables, are not soluble in water, and the place of this liquid must be supplied by alcohol, in which the plant must be digested; evaporation will separate the alcohol from the resin which it holds in solution. In order to avoid the accidents that might occur from the dispersion in the atmosphere of a very inflammable vapor. the evaporation must be so conducted that the dissolvent may be received into an alembic or close vessel.

In addition to the methods of preserving fruits by drying, and by reducing their juices to the state of sirups and jellies by natural or artificial heat, M. de Montgolfin has applied the action of the air pump with great success. I have tasted juices prepared and thickened in this manner, and I thought they were much superior to those that had been evaporated in either of the modes hitberto usually practised. I do not doubt that, when this method becomes better known, it will be generally adopted.

[*From the Domestic Encyclopedia.*]

Vegetation

Is the natural process by which plants receive their nourishment.

Naturalists have formed various conjectures, to account for the mysterious phenomena occuring in vegetable nature; and though unable to discover the primary source from which plants are enlivened, yet it is now agreed, and proved, that all vegetables originate from seeds, each of which comprehends three parts, namely: 1. The *cotyledons*, or two porous lateral bodies or lobes, that imbibe moisture: 2. The *radicle*, or *eye*, which appears between the lobes: and, 3. The *plumula*, a small round body attached to the radicle, though wholly concealed within the cotyledons, forming the part that shoots upward.

If a seed be deposited in the earth, in a favourable situation, it imbibes moisture, and evolves carbonic acid gas; but if any oxygen gas be present, it is gradually absorbed by the seed, and the farinaceous matter, contained in the cotyledons, acquires a saccharine taste. Numerous vessels then appear in the lobes which convey the nutriment to the radicle, that progressively increases in size, and at length assumes the form of a root; strikes downwards into the earth; and thence derives the nourishment necessary for the support of the future plant. Now the cotyledons shoot above the ground, become leaves, and form what botanists have termed the *seminal leaves*. Thus, the *plumula* is gradually enlarged, and rises out of the earth, spreading itself into branches, &c. after which the seminal leaves wither and decay, while the different processes of vegetation are carried on in the plant, without their assistance.

Plants are very various, and of course, the structure of each species must have many peculiarities. Trees have principally engaged the attention of anatomists. We shall therefore take a tree as an instance of that structure of plants: and we shall do it the more readily, as the greater number of vegetables are provided with analogous organs dedicated to similar uses.

A tree is composed of a root, a trunk, and branches. Each consists of three parts, the bark, the wood, and the pith.

The *bark* is the outermost part of the tree. It is usually of a green colour. If we inspect a horizontal section, we shall perceive that the bark itself is composed of three distinct bodies. The outermost of these, is called *epidermis*, the middlemost, is called *parenchyma*, and the innermost, or that next the root, is called the *cortical layers*.

The *epidermis*, is a thin transparent membrane, which covers all the outside of the bark. It is pretty tough, is reproduced when rubbed off. In old trees it cracks and decays, and a new *epidermis* is formed. Hence, old trees have a rough surface.

The *parenchyma*, lies immediately below the epidermis; it is of a deep green colour, very tender and succulent. Both in it, and the epidermis there are numberless interstices which have been compared to so many small bladders.

The *cortical layers*, form the innermost part of the bark, or that next the wood. They consist of several thin membranes, lying the one above the other; and their number appears to increase with the age of the plant.

The wood consists of concentric layers the number of which increases with the age of the part. Next the bark, the wood is much softer and whiter and more juicy than the rest, and is called *alburnum* or *aubier*. The perfect wood is browner and harder, and the layers increase in density, the nearer they are to the centre.

The pith occupies the centre of the wood. It is a spongy body, containing numerous cells. In young shoots it is very succulent, but it becomes dry, as the plant advances, and finally disappears.

The leaves are attached to the branches of plants by short foot-stalks. The whole leaf is covered with the epidermis of the plant; containing many glands.

Plants are continually increasing in size. New matter is continually making its appearance in them, and this matter they must receive by some channel or other. Plants then require food as well as animals. Now, what is this food, and whence do they derive it? These questions can only be examined by an attentive survey of the substances which are contained in vegetables, and an examination of those substances which are necessary for their vegetation.—This subject has already been treated of, under articles, *food of plants*, and *manure*. Some additional remarks shall now be given.

The analysis of vegetables affords but three essential principles, namely, *carbon, hydrogen, and oxygen*, or charcoal, inflammable air, and pure air; and the proportions between these principles form all the shades, varieties, modifications, which the vegetable creation exhibits. Analysis further shews, that vegetable fibre, when cleared of all extraneous matter, is scarcely any thing else than a congeries of carbon. But how is carbon conveyed into the body of the plant? It is well known, that pure carbon, such as is used for burning mixed with pure, dry earth, affords no nourishment to vegetables: and it is also known, that when dead plants are so far decomposed, that their texture is softened or destroyed, living vegetables imbibe all their constituent principles.—This difference appears to arise from hence, that in the last case, the carbon remaining dissolved in the oily, resinous, or alkaline principle, the water, which has the property of disjoining these natural combinations, serves as a vehicle to convey them into the vegetable system. Air, heat, acids, and even rest alone, are sufficient to precipitate the carbon; so that, the agents proper to facilitate the concretion of the fibre, and to promote nutrition, are every where to be found. The principle of life, which governs and animates every organ, suitably divides this nutritive matter. It modifies the action of external agents, and presides over all the operations of this living laboratory. Hence it is easy to see, that hydrogen, carbon, or oxygen, predominates in the plant, according to the nature of the soil, exposure and climate, and according to the proportions in which these nutritive principles are presented.

Since the only part of plants which is contiguous to the soil is the root, and since the plant perishes when the root is pulled out of the ground, it is evident, that the food of plants must be imbibed by the roots. It is highly probable that the *great* changes, at best, which the food undergoes after absorption, are produced, not in the roots, but in other parts of the plant. The sap, as Dr. Hales has shown us, ascends with such impetuosity from the cut end of a vine branch, that it supported a column of mercury 32½ inches high. It is certain that the sap ascends through the wood, and not through the bark of the tree; for a plant continues to grow, even when stripped of a great part of its bark, which could not happen, if the sap ascended through the bark.

It is impossible to account for the motion of the sap in plants by capillary attraction, or by any mechanical or chemical principles whatever; we know indeed, that heat is an agent, but its influence cannot be owing to its dilating power; for unless the sap vessels of plants were furnished with valves, (and they have no valves) dilatation would rather retard than promote the ascent of the sap.

We must, therefore, ascribe it to some other cause; the vessels themselves must certainly act. Many philosophers have seen the necessity of this, and have accordingly ascribed the ascent of the sap to *irritability*. Saussure supposes, that the sap enters the open mouths of the vessels, at the extremity of the roots; that these mouths then contract, and by that contraction propel the sap upwards; that this contraction gradually follows the sap, pushing it up from the extremity of the root to the summit of the plant.

This irritable principle is seen in many plants, particularly in the *stamina* of the barberries, which are thrown into motion when touched. *(To be continued.)*

For Burns and Scalds.—Mix in a bottle three ounces of olive oil and four ounces of lime water. Apply the mixture to the part burned five or six times a day with a feather.—Linseed oil is equally as good as olive oil.

Young Men's Department.

Chemical Catechism—Chapter IX.

[*From Parkes' Chemical Catechism.*]

OF SIMPLE COMBUSTIBLES.

What is a simple substance?

Those bodies* which have never yet been decomposed, nor formed by art, are called simple substances.

How many simple substances are there?

Very lately the simple substances were said to amount to more than 50 in number;† but since the truly interesting and very important discoveries of Sir Humphrey Davy, it is scarcely possible to say what substances are not compound bodies.

Can you enumerate what are now deemed simple substances?

All the simple substances that we are acquainted with are fifty-two;‡ viz: electricity, magnetism, light, caloric, chlorine, oxygen, nitrogen, iodine,§ the metals, (reckoning as such the bases of potash, soda, and some of the earths,) and the simple combustibles, carbon, phosphorus, sulphur, hydrogen,* boron, and fluorine.

---

* In this country, apples, pumpkins, squashes, and peaches are kept by drying.—Tr.

* The most minute particles into which any compound substance can be divided similar to each other, and to the substance of which they are parts are termed the *integrant* particles: thus the smallest atom of powdered marble is still marble; but if by chemical means the calcium, the carbon, and the oxygen of this marble be separated, we shall then have the *elementary* or constituent particles.

Suppose a little common salt were reduced to powder, even though it be ground as fine as could be effected by art, still every single particle, however minute, would consist of a particle of sodium and a particle of chlorine; common salt being a compound body incapable of decomposition by mechanical means. But if we take a piece of sulphur and pulverize that in the same way, every particle will be a homogeneous body, sulphur being one of the simple substances.

† If these substances were all capable of combining, the compounds formed by them would amount to many thousands; but several of them cannot be united by any means we know of.

‡ Of these simple substances it may be remarked that four are imponderable; four others exist in a gaseous state; six are bases of acids; and thirty-eight are metallic bodies.

§ Iodine is a peculiar substance procured from kelp; it pos-

Is it well ascertained that these are all simple substances?

It is extremely probable that some of these bodies may be compound, but as no mode has yet been discovered of decompounding any of them, it will be more conducive to science, to consider them, for the present, as simple undecomposable bodies.

Having already examined the nature of all these substances, except the combustibles, we shall now enter upon the consideration of that class of bodies.—Endeavor, therefore, to enumerate the simple combustibles.

Besides the metals there are six simple combustibles, viz: hydrogen, sulphur, phosphorus, carbon, boron, and fluorine.

Why are these substances called simple combustibles?

They are called simple because we have no proof that they are compounded: whereas oil, spirit of wine, wax, tallow, and other combustible bodies, are well known to consist of two ingredients at the least.

It will be necessary to examine each of these substances separately:—therefore, what is the nature of hydrogen.†

Hydrogen is the basis of what has been generally called inflammable air,‡ and is one of the component parts, of water,§ but it cannot be exhibited in a separate state. We therefore know it only in combination with other substances,‖ or in the gaseous form, that is, with caloric.¶

In what other compounds is hydrogen an ingredient?

Hydrogen gas may be combined with water, sulphur, phosphorus, or with carbon.

What is the nature of the compound of hydrogen and water?

Water may be made, by pressure, to absorb a considerable portion of hydrogen gas. It is called hydrogenated water, and is said to be useful in medicine.

What is the nature of the compound of hydrogen and sulphur?

Sulphur dissolved in this gas forms sulphuretted hydrogen gas, which is a very fetid elastic fluid, somewhat heavier than atmospheric air and soluble in water.

What are the properties of sulphuretted hydrogen gas?

SULPHURETTED HYDROGEN gas** is transparent and colourless; it has the property of inflammability, is nauseous to the taste as well as fetid to the smell; it possesses all the characters of an acid: it combines with earths, alkalies, and with several of the metallic oxides; and forms with them those substances called *hydrosulphurets*.

What are the properties of the hydrosulphurets?

The HYDROSULPHURETS are generally soluble in water, and their solutions precipitate the metallic oxides, from metallic solutions. Exposure to the air, however, decomposes these hydrosulphurets when dissolved in water,* and partially converts them into hydroguretted sulphurets.

How many compounds are there of sulphur and hydrogen with the alkaline and earthy bases?

There are three distinct combinations of sulphur and hydrogen with the earths and alkalies, which differ in their properties in consequence of the difference there is in the proportions in which their constituent parts are combined.

Can you explain what difference there is in the composition of these three distinct classes of substances?

The first, which are called *sulphurets*, are merely compounds of sulphur united with some earthy or alkaline base; the second, called *hydrosulphurets*, are formed by the union of some base with sulphuretted hydrogen; and the third called *hydroguretted sulphurets*, consist of a base united with supersulphuretted hydrogen.

What is the nature of supersulphuretted hydrogen?

SUPERSULPHURETTED HYDROGEN is merely sulphuretted hydrogen combnied with an additional proportion of sulphur; that is to say, one part of hydrogen combines with 15 parts of sulphur to form sulphuretted hydrogen, and with 30 parts of sulphur to constitute supersulphuretted hydrogen.

What is the nature of the combination of hydrogen and phosphorus?

Hydrogen gas when combined with phosphorus forms *phosphuretted hydrogen gas*. This gas has a fetid putrid smell, and takes fire whenever it comes in contact with atmospheric air.

What is the nature of the combination of hydrogen with carbon?

This elastic substance, which is called *carburetted hydrogen gas*,† is carbon dissolved in hydrogen; it has likewise been called heavy inflammable air. It is this gaseous compound which has occasioned so many dreadful accidents in coal-pits. The miners call it the *fire-damp*.‡

What is meant by SUPER-CARBURETTED HYDROGEN?

This is a gaseous compound of carbon and hydrogen, containing exactly twice as much carbon as the carburetted hydrogen gas. It is extremely inflammable, and emits more light during combustion than is given out by the inflammation of that gas. It has been called *olefiant gas*.

What is the origin of SULPHUR?

Sulphur is found in most parts of the world§ combined with metals, from which it is procured by roasting; it also flows from volcanos; it is sublimed from the sulphurous grounds in Italy, and is found in many mineral waters,‖ combined with hydrogen.

What is the nature of sulphur?

Sulphur or brimstone as it is sometimes called, is a solid, opaque, combustible¶ substance, of a pale yellow colour, insoluble in water, very brittle, and possessing a peculiar taste and smell. Its specific gravity is 1.990, or nearly twice as heavy as water, and it is a non-conductor of electricity.—It has various uses in medicine and the arts.

*What compounds** are formed by means of sulphur?*

Sulphur is the base of several compounds; it unites with oxygen, hydrogen, carbon, phosphorus, the alkalies, the metals, and with some of the earths.*

What are the compounds of sulphur and oxygen?

If sulphur be kept in fusion in atmospheric air, it absorbs a small quantity of oxygen, and forms oxide of sulphur; if it be heated sufficiently to take fire, it burns with a pale blue flame, and becomes converted to *sulphurous* acid; but if sulphur be burned in pure oxygen, it absorbs the full dose of this gas, and *sulphuric* acid is the product.

What are the compounds of sulphur and the alkalies?

Sulphur will combine with potash, with soda, and with ammonia; which compounds possess several curious and interesting properties.

What are the general characteristics of the alkaline and earthy sulphurets?

They are hard substances of a brown colour, resembling the liver of animals; they absorb water from the atmosphere, and then emit a fetid odor, similar to that of putrid eggs.†—They have the property of decomposing water, and by that process become partially converted to alkaline or earthy sulphates.

What knowledge have we acquired of the combinations of sulphur with the earths and metals?

Sulphur may be combined artificially with most of the metals, and with some earths: but many of the metallic sulphurets are found native in great abundance.

---

sesses the singular property of being convertible into a violet vapor by heat.

* If we omit the earths and alkalies (and there is abundant evidence that these are compound bodies,) most of the simple substances are combustible, or bear some relation to combustion. Light and caloric are evolved during combustion; oxygen is the principal agent of combustion: and hydrogen, sulphur, phosphorus, carbon, and the metals, are the subjects, or the true instruments of this process.

† Mr. Cavendish was the first person who examined hydrogen gas and pointed out its nature. This was in the year 1766. Dr. Black then suggested the propriety of applying it to the inflation of air balloons; and Mr. Cavallo was the first who put it in practice. This gas is about thirteen times lighter than atmospheric air.

‡ Like all other combustibles, hydrogen will not burn unless in contact with atmospheric air, or some substance that contains oxygen. If a portion of atmospheric air be mixed with this gas, and fire be applied, it will explode with violence. It is related of Pilatre de Rosier, that having mixed one part of common air with nine parts of hydrogen gas, and drawn the mixture into his lungs, it caught fire by accident as he respired it, and the whole of the gas exploded in his mouth and nearly deprived him of life. The shock was so violent, that at first he thought the whole of his teeth had been driven out, but fortunately he received no lasting injury.

§ Hydrogen is the most inflammable substance we are acquainted with; that is, it combines with more oxygen than any other body, and occasions more heat by its combustion. It may be remarked that oxygen is *mild* when in the proportion of 21 per cent in atmospheric air, and highly *corrosive* in the proportion of 74 per cent in nitric acid or even in that of 49 per cent in sulphuric acid:—How is it then, that it is found in the ratio of 88 per cent in water, and that this compound, compared with the others, should be perfectly mild and innocent! Instances of a similar accommodation of the elementary substances have been adduced; and though we cannot comprehend the nature of their operation, we can perceive that the ultimate end of the Creator is our convenience and happiness. See pages 48 and 160. Most oxidized substances, when taken internally, act perceptibly on the system; yet water, the most oxidized of all others, has comparatively little influence, because its oxygen is so forcibly retained and so completely neutralized by the hydrogen. Had it been otherwise, what is now the most salubrious beverage would have operated as a corrosive poison.

Oil, tallow, wax, &c. used for producing light, do all acquire their power of burning *with flame*, from the hydrogen, which is a component part of all these substances.

‖ Although hydrogen when in an aërial form is the lightest of all known substances, yet when imbibed by living vegetables it becomes a solid, so as to form wax, resin, &c. and in combination with oxygen it constitutes water, which has the property of becoming either solid, fluid, or aëriform.

¶ A mixture of oxygen and hydrogen gases produces the most powerful heat yet known.

** This gas was long known by the name of *hepatic* gas, because the substances from which it was first obtained were called *hepars* or livers of sulphur.

When this gas is set on fire in contact with oxygen gas, it burns with a pale blue flame without exploding. It will of itself extinguish burning bodies, and destroy animals which are made to inhale it.

Sulphuretted hydrogen gas is decomposed by atmospheric air. The oxygen of the atmosphere combines with the hydrogen and forms water, while the sulphur is precipitated.—The sulphur which is found in the neighborhood of mineral springs originates from this cause.

The fetid smell which arises from house-drains is owing, in a great measure, to a mixture of this gas with other putrid effluvia. As the diffusion of this noxious matter within our dwellings tends to produce disease and mortality, it cannot be too generally known that a cheap and simple apparatus has been contrived for carrying off the waste water, &c. of sinks, and which at the same time prevents the possibility of any air ever returning back into the house from thence, or from any drain which may be connected with it. It is known by the name of a *stink trap*, and may be had of some of the ironmongers in London. [Chloride of soda will do this; see Cultivator for Sept.]

* The waters of Harrowgate, Aix la Chapelle, and others of a similar nature, owe their medicinal properties to sulphuretted hydrogen gas and muriate of soda. The *salt of bitumen* of the Hindoos, which is almost the only article of Hindoo physic, and is sold in every village, is chiefly composed of muriate of soda and sulphuretted hydrogen. It is taken by these people for every complaint. The farriers give it to the horses, and seem to understand the principle upon which it acts; for when they have given a dose to the animal, they always give him water to extricate the gas.—Henderson on *Hindoo Physic*.

† In hot weather this gas is formed at the bottom of stagnant waters, and may readily be collected at their surface, by suspending a bottle of water over the pool, similar to the decanting of gases over a pneumatic trough, and stirring up the mud to disengage the carburetted hydrogen.

This gas generally contains a portion of carbonic acid mixed with it. Both these aëriform fluids are produced by the decomposition of water by putrid animal and vegetable matter. Such decompositions take place chiefly when the sun shines upon these waters, caloric being necessary to all gaseous compounds.

‡ What renders this gas so extremely dangerous in mines is the circumstance that whenever the atmosphere of a mine becomes charged with more than one-thirteenth of its volume of carburetted hydrogen gas, the whole becomes explosive. It is, however, now expected that the safety-lamp of Sir Humphrey Davy, which is a most important discovery, will be a means of lessening the number of these accidents.

§ Sulphur is procured in large quantities from martial pyrites and other metallic ores. It is also found in abundance in the state of native sulphur, as it is called, near several volcanos, in different parts of the world. According to Dr. Anderson, there are mines of it in the kingdom of Thibet.

‖ Sulphur has been discovered in cresses, horse-radish, and several other vegetables. It is also evolved from animal substances, during their putrefaction, in combination with hydrogen. The change which silver undergoes when immersed in an egg, shows the presence of sulphuretted hydrogen.

¶ Sulphur during its combustion combines with oxygen, and becomes an incombustible substance. Like phosphorus, it is eminently combustible, owing to its great affinity for oxygen.

**"Nature employs sulpher in a great number of her operations; she presents it under many forms among fossils; charges with it the waters denominated sulphurous; mineralizes with it the metals; causes it to pass into vegetable and animal fibres and exhibits it to chemists in an infinite number of combinations."

* Sulphur is used in large quantities for making gunpowder. When exhibited as a medicine, it penetrates to the extremities of the most minute vessels, and impregnates all the secretions; as may be perceived by those who have taken it for any length of time. Sulphur has many uses in the arts, and has been employed with advantage in stopping the progress of fermentation in wines and other fermented liquors.

† Sulphuret of potash is formed by the explosion of gunpowder, and it is this compound which occasions that peculiar smell which a gun usually has after firing.

---

*Moneys received between the 1st of August and 20th Sept. in sums of $5 and over. The total receipts are included from post-offices marked with an asterisk.**

MULBERRY TREES.—25,000 Multicaulis, Alpine and Expansa Mulberry trees, and a few thousand Silk Worms Eggs, for sale by S. E. GIBBS & SON, West end of Long-Island. Address them at Brooklyn. October, 1839. 3t.

DURHAM CATTLE.—Short-Horned Durham Cattle, of pure blood, bred by Charles Henry Hall, of N. York, comprising Bulls, Cows and Heifers, of all ages. In point of excellence, the proprietor of these cattle will not hesitate to compete at any fair with those lately imported from England, or with any others bred in this country. Their size, beauty of form, and their milking properties, are seldom equalled. Some of these animals have taken premiums, and among them the gold and silver medals of the American Institute, for two succussive years.

For terms, examinations, and pedigrees, apply to the subscriber at Greenbush, Rensselaer county, where the animals are; or to DANIEL A. WEBSTER, No. 67 State-street, Albany. Greenbush, Sept. 2, 1839.

oct.2t WILLIAM DEWEY, Agent.

DURHAM AND DEVONSHIRE CATTLE and SAXONY SHEEP, for sale by the subscriber.

1. The Bull *Memnon*, ftom the herd of F. Rotch, Esq. of Butternuts, N. Y. Pedigree No. 2,297, English Herd Book.
2. A four years old full blood Cow, a beautiful specimen of the Devonshire and Durham cross, with her calf, a heifer, six months old, by Memnon.
3. A bull calf, two and a half months old, by Memnon, dam Experiment.
4. From 70 to 80 Ewes, 40 to 50 Lambs, and 30 Rams, from my flock of full blood Electoral Saxon Sheep, selected by myself from the purest race in Saxony. H. D. GROVE,

oct.1t Buskirk's Bridge P. O. Wash. co. N. Y.

PURE SOUTH-DOWN SHEEP.—The subscriber will sell at public auction on Thursday the 10th day of October next, at the city of Rochester, sixty-five full blooded South-Down Bucks and Ewes. Some of them have been imported by himself direct from England, and with their produce are not surpassed by any of the same breed in this country. Every sheep offered will be sold without reserve to the highest bidder, and a warrantee certificate given to the purchaser.

The place of sale being in Rochester, the sheep can be shipped to any part of the country desired.

Persons wishing to see the above sheep, can, at any time, previous to the sale, by calling on the subscriber at his residence in Riga, Monroe county, N. Y.

This breed of sheep needs no recommendation to those who are acquainted with them; they are the strongest constitution, easiest kept, apt to fatness, very quiet, less liable to disease, than any other breed of sheep.

oct.1t JAMES PARSONS.

MORUS MULTICAULIS.—25,000 trees for sale, either in quantities or all together, and to be delivered at any time that may best suit the purchaser. They are from imported cuttings, of the genuine Morus Multicaulis, were planted in May last, and are of the most vigorous growth, measuring from three to five feet in heighth, with large collateral branches. Purchasers are invited to call and see them, at the residence of Gen. Morgan Lewis, Staatsburgh, Dutchess county, state of New-York, where the owner lives, as he thinks they will not suffer by a comparison, with any in the United States. Staatsburgh, Dutchess co. Sept. 11, 1839. [oct. 4t] MATURIN LIVINGSTON.

MULBERRY TREES.—A few thousand Mulberry Trees are for sale at the Albany Nursery. They consist of the Multicaulis, Brussa, Chinese, that is, the product of Chinese seed, and the common white. The prices will depend upon size and quality. The Brussa is more hardy than the common, and the Chinese about as hardy; and the three kinds are believed to be equal, if not superior, to the Multicaulis, for silk; though it is proper to add, none of the mulberries that we have tried are propagated with so much facility, from buds and cuttings, as the multicaulis. The prices will be conformed to the average market price. tf

---

ALBANY NURSERY.—This establishment now offers perhaps the best collection of Pears now in the country; [see the June number of the Cultivator.] Also, Apples, Peaches, Plums, Ornamental Trees, Green-House Plants, &c. &c. A catalogue will soon be printed, and forwarded to order. Address J. BUEL & Co. post-paid. tf

---

☞ **ROHAN POTATOES.**—Orders received for Rohan Potatoes, at $5 per Barrel, to be forwarded, as may be directed, without delay, by J. BUEL. tf

---

ROHAN POTATOES.—The subscriber is now prepared to furnish the above very valuable root for transportation, at five dollars per barrel, delivered at Albany.—Persons living at a distance, will find it to their interest to forward their orders early, so they will reach their destination before cold weather sets in. Orders enclosing five dollars, (postage paid) or more, will meet with immediate attention.

CALEB N. BEMENT.

Three-Hills Farm, Albany, Oct. 1st, 1839.-3t

SOUTH-DOWN SHEEP.—The subscriber will sell the following Sheep, delivered at Albany, if applied for soon, viz:

			Price
1	full bred South-Down Buck, (imported,)	3 years old,	$80
1	do do do	1 year old,	40
6	do do do	Lambs,	30

10 do South and Hampshire Down Ewes, (some of which were imported by Mr. Hawes, in 1833,) very old, price from $20 to $25. Eight Ewes from 1 to 2 years old, half South Down and half Bakewell, price $10.

All letters, postage paid, will be punctually attended to.

2 CALEB N. BEMENT, Three Hills Farm, Albany.

FOR SALE—TWO SOUTH-DOWN BUCK LAMBS.—The subscriber imported, in the fall of 1837, two ewes and a buck, selected from the Earl of Leicester's flock, (Holkham,) of which the above is the progeny. Near Dobb's Ferry, Pa. July 28, 1839.

Sept-tf JAMES A. HAMILTON.

THE SUBSCRIBER has located in Albany, where he is manufacturing his machines for thrashing and cleaning grain. He may be found at **53** North-Market-st. or at his machine shop on Patroon's Creek, near the Manor House. Sept. 2, 1839. [oct. 3t] JOHN A. PITTS.

☞ **FOR SALE**—The subscriber wishing to close up his business, offers for sale ☜ the valuable Iron and Lumber Establishment, formerly owned and occupied by Penfield & Taft, situated on Putts creek, six miles from Lake Champlain, in Crown Point, Essex co. N. Y. The premises in question consist of a valuable water power, with a fall of more than 100 feet within sixty rods; on which there is now in operation a Grist-Mill with three run of stones, propelled by an overshot wheel; two Saw-Mills, one with overshot wheel and double gear, all nearly new and in good order; a Forge with two fires; and a machine shop for pounding and separating ore. The water for propelling these works is held in reserve by four ponds or reservoirs on the premises; the upper one being about 2½ miles in length, forming an ample reservoir for the whole works below, and affording sufficient water in itself for driving a forge with four fires and a rolling mill.

Adjoining the works are **600** acres of land, one-fourth of which is under good cultivation; on which are five dwelling-houses, convenient barns and out-houses, a store, blacksmith shop, and buildings convenient for other purposes.

There is also **1,000** acres of fine timbered land lying two or three miles from the above described works. Also, about five miles distant are **800** acres fine timbered land, on which are two Saw-Mills, and one of the richest, most extensive and valuable beds of iron ore yet found in the U. States.

Also, **1,900** acres of land in the towns of Schroon and West Moriah, Essex co. the greater part of which is covered with pine timber; 100 acres of which is under good culture, and on which is a good saw-mill, blacksmith shop, several dwelling-houses, barns and out-houses.

Also, one-half of a farm of 130 acres, situate on Lake Champlain, near the mouth of Putts creek, 2-3ds of it under good improvement; on which there is a large and convenient wharf.

On examining the above described premises, they will be found to combine unparalleled advantages for prosecuting an extensive business in the manufacture of lumber and iron, and for the sale of ore.

Such parts or parcels of the premises as are necessary for prosecuting the manufacture of iron and the sale of ore, will be disposed of separately from, or in connexion with, the lumbering establishment, as may suit the purchaser.

For the terms of sale, and all further particulars, inquire of the subscriber on the premises. ALLEN PENFIELD.

TO THE SILK GROWERS OF THE UNITED STATES.—In consequence of the difficulty of purchasing cocoons in the present state of the silk culture in this country, (competent agents for the purchase, at a distance, are not at present to be had,) and as the reeling of the cocoons is the foundation of the whole business in a national point of view, the subscriber is induced to receive cocoons from all parts of the country, to be reeled on shares, in the Italian style, for exportation; the silk to be returned to the owner, or the market price in cash, as may be desired. Persons sending cocoons for reeling, will please name for what purpose it is intended, whether for *Sewing Silk*, which requires 20 to 25 cocoons (or fibres to the thread,) or the finer qualities for weaving, say from 6 to 10, inclusive, and the product will necessarily vary with the *quality* of the cocoons. Worms poorly fed will produce light thin cocoons, and many of them so light that they will fill with water and sink, and consequently be lost. Cultivators will therefore see the importance of producing good cocoons—the largest are not always the best. The cocoons should be firm and hard to the touch. A large spongy cocoon will not yield much silk.

The terms for reeling for the present season, will be 20 per cent of the silk produced from each parcel of cocoons, which as they will be necessarily received in small parcels, will be attended with more trouble and expense than in after years, when the feeding of silk worms will be as extensively followed as is now the growing of cotton.

SAMUEL WHITMARSH.

Northampton, Mass. July 8, 1839.

N. B. The cocoons should be thoroughly *seasoned* before packing; they should not be *damp*, as they will *heat* in transportation. All bad cocoons in which the worms have died, should be rejected. They may be packed in flour barrels or boxes, with *holes* bored in the top and bottom, to give air, or in bags within crates, or in any way to prevent crushing them. They should not be crowded, but shaken into the barrels with the floss on. They may be shipped from any part of the U. States, direct to Hartford or New-Haven, Conn. whence they will be received by the canal or river boats, directed to "*Samuel Whitmarsh*, Northampton, Mass." sept-2t.

IMPORTED CATTLE—BERKSHIRE PIGS.—The subscriber intending to return to England, offers for sale his stock of Imported Durham Short Horned Cattle and Berkshire Pigs, at his residence, English neighborhood, Bergen county New-Jersey, five miles from New-York. The stock consists of 15 head of milking cows, 1 two-year old heifer, 4 one-year old heifers, and from 8 to 10 spring calves. Four of the above cows are imported, and the remainder are got by the imported Herd-Book Bulls Dishley, Durham, Wye-Comet, Hall's Comet, Memnon, Admiral, Denton, &c.

BERKSHIRE PIGS.—Ten breeding Sows, in pig and with pigs by them at the present time; from 40 to 50 Pigs ready for delivery at any time, at prices from $10 to $20 per pair, delivered in New-York.

The imported Herd-Book bred bull Bloomsbury is with the Cows for the season, and from present appearance will soon all be in calf. The yearlings and spring calves are all by my bull Snow-Ball, late Minevis, by Wye-Comet, dam Nelle, bred by Israel Munson, Esq. of Boston, got by the imported bull Admiral; grand-dam Rosa, bred by Mr. Munson, by the imported bull Denton, owned by Stephen Williams, of Northborough, Mass.: great-grand-dam Tuberose, bred by Mr. Wetherall, and imported by Mr. Munson.

For further particulars, see Herd-Book; Dishley, page 63; Durham, page 567; Wye-Comet, page 200; Admiral, page 2; Denton, page 43; Tuberose, page 524.

BENJAMIN BRENTNALL, English neighborhood,
sept-3t. Bergen co. N. J. 5 miles from N. Y.

SOUTH-DOWN BUCKS.—Two two year old very superior South Down Bucks, clothed with fine wool and long enough for combing, were imported last April, direct from England, from the flock of the late John Ellman, Esq. of Glynde, near Lewes, Sussex, and are for sale at one hundred dollars each, or to be let for the season at fifty dollars each, by the personal friend of the breeder.

OBADIAH ELLIOT.

Elizabethtown, N. J. Aug. 20, 1839. s3t

☞ The Genesee Farmer and Farmers' Cabinet, will give the above two insertions, and send bill to advertiser.

BERKSHIRE PIGS.—The subscribers are ready to receive orders for their fall litters of Berkshire Pigs.—Several of their sows will come in from the 25th of August to the 5th of September. Orders for the south can be sent to New-York every day in the week, (Sundays excepted,) and reshipped by a faithful person, without charge, except for freight to, or cartage in, New-York. Orders or letters of inquiry, *post-paid*, will reeeive immediate attention.

sept-2t. H. & J. CARPENTER, Norwich, Con.

ALBANY SEED STORE, GARDEN and AGRICULTURAL SEEDS, IMPLEMENTS, TOOLS, &c. kept constantly for sale at his Seed Store, 317 North Market-street, wholesale and retail, consisting of a large assortment. It is the intention of the proprietor to test all seeds of which there is any doubt respecting their vitality, by sowing a few seeds in a small pot, before offering them for sale. And purchasers can test for themselves, any seeds of which they are distrustful, by sowing a few in a box of fine earth, and placing it in a warm room, exposed to the sun, where, if kept moist, the seed, if good, will vegetate in a reasonable time. In all cases where seeds prove to be bad, they will be replaced by others, or any reasonable satisfaction made. The proprietor has enlarged his establishment and increased his supplies, and with his experience in the business, together with his facilities for obtaining supplies, through Mr. GEORGE C. THORBURN, and his extensive correspondence and facilities for obtaining seeds, he flatters himself he will be able fully to meet the wishes and expectations of the public, and make the *ALBANY SEED STORE and AGRICULTURAL REPOSITORY* worthy of the high character it has already attained.

Persons ordering Seeds and Implements from a distance, with whom I am unacquainted, without remitting payment, are expected to give references in this city or New-York.

Sept-tf WILLIAM THORBURN.

NEW-YORK URATE AND POUDRETTE COMPANY, not incorporated, but carried on by individual enterprise. The manures are not divided among the stockholders, as are those belonging to another establishment, but sold to applicants for cash on delivery. Orders are supplied in the order of time in which they are received. Urate 50 cents and Poudrette 40 cents per bushel, with contingent charges for bags or barrels, &c.

The company are daily preparing for use, during the warm dry weather, the materials collected during the past winter, and will have several thousand bushels ready before the first of October next. The material is disinfected and rendered free from offensive smell by a compound, every part of which is in itself a good manure. The experience of the past and present year, 1838 and 1839, on Long Island, has satisfied many of the farmers that these manures have the quickest operation upon vegetable matter, producing greater abundanee, and the cheapest of any manure they have ever tried.

Amended instructions for their use, the result of practical experience, will be furnished on application. The effect of Poudrette upon grape vines and morus multicaulis is beyond all comparison. This company are erecting large and extensive works in the vicinity of the city of New-York to prepare the manures; and farmers and gardeners may confidently rely on a supply. Orders, post paid, directed to "The New-York Urate and Poudrette Company," box number 1,211, post-office, New-York, or sent to the store of STILLWELL & DEY, number 365, Fulton-street, Brooklyn, will be attended to. *New-York, July* 17, 1839.

The company will be very much obliged to gentlemen who have used the manures, to give them a statement in writing what has been the result of their use and experiments in relation to them. aug-4t.

FOR SALE—A Splendid Country Seat in the Highlands, on the Hudson River. That beautiful country residence, known by the name of the BEVERLY ESTATE, containing four hundred acres of land, about two hundred of which are fine level arable soil, of an excellent quality, in a good state of cultivation, and not surpassed by any on the river for fertility; the remainder is fine and thrifty timber land. The situation is the most eligible on the Hudson, extending one mile and a half on the river, with a bold shore and convenient dock, nearly opposite West-Point, and within fifty miles of New-York. The prospect is extensive and diversified, reaching from St. Anthony's Peak on the south, to the bay and city of Newburgh on the north. This estate can conveniently be divided into three farms, giving an equal proportion of front on the river, and of arable and timber land to each. Almost every enclosure is supplied with living springs of the purest water. There is on said estate a plain house, (formerly the head-quarters of Gen. Arnold;) also out-houses necessary to carry on the business of the farm. The single fact that during the whole time the cholera raged throughout the state, not one case occurred within ten miles of this place, is sufficient to prove the unrivalled salubrity of the situation. The facilities of intercourse with the city, that can be reached in four hours, by means of numerous steam-boats, are great, and daily increasing, both as regards pleasure, and the convenience of a near market for produce of every description.

For conditions of sale, apply to STEPHEN A. HALSEY, 189 Water-street, New-York, or RICHARD D. ARDEN, on the adjoining farm. Ardenia, 23d April, 1839. j6t

FROM THE STEAM PRESS OF
PACKARD, VAN BENTHUYSEN & Co.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. NOVEMBER 1839. No. 10.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—Lewis Hill & Co. Richmond, Va.; Bell & Entwistle, Alexandria, D. C.; Gideon B. Smith, Baltimore, Md.; Judah Dobson, bookseller, D. Landreith, and M. S. Powell, seedsmen, Philadelphia; Israel Post, bookseller, 88 Bowery, Alex. Smith, seedsman, P. Wakeman, office of the American Institute, Broadway, New-York; Hovey & Co. Merchants' Row, Boston; Alex. Walsh, Lansingburgh, and Wm. Thorburn, Albany, gratuitous agents; John Thorburn, seedsman and general agent, St. Louis, Mo. E. Valentine, Johnson's Springs, Va. See No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

THE LATE JESSE BUEL.

Since the last publication of the Cultivator, death has abruptly terminated the existence of its well-known and respected Editor. He sank, after a brief struggle, beneath a severe illness, which seized him while absent from his home, and engaged in the pursuit of his favorite occupation. He breathed his last, at Danbury, Connecticut, on the 6th ultimo, in the sixty-second year of his age. This sudden bereavement has called forth the sympathy of the entire community; and while others are expressing their sense of the common loss, it seems fitting that the paper, which he first established, and in which he delighted to the last, should furnish some few mementos of his useful life.

JESSE BUEL was born at Coventry, Conn. on the 4th of January, 1778. In early boyhood he removed with his parents to Rutland, Vermont, where he became an apprentice to the printing business, in the office of Mr. Lyons. Thence he went, at the age of 18 to the city of New-York, remained there during the prevalence of the yellow fever, bought out his time, and having formed a partnership with Mr. Moffit, at Troy, he there established the Budget. In 1801, he married, moved to Poughkeepsie, and commenced the Guardian, afterwards called the Political Barometer. In 1803, he came to Kingston and established the Plebeian. In 1813, he settled permanently in this city, and commenced the Albany Argus. He continued to edit that paper and to discharge the duties of State Printer, until 1821, when he retired to his farm in the vicinity of this city. Subsequently to this period, he represented the county for several years in the Assembly of the State; received, in 1836, the support of the whig party of New-York, for the office of Governor; and was, at the time of his death, a Regent of the University. In these several stations, he manifested a soundness of judgment and a purity of purpose, that won for him the respect of all parties, and the reputation of an eminently honest man.

But these incidental interruptions were never suffered to divert his attention, for any length of time, from the great object of his interest, the advancement of agricultural science. From the period of his retirement to his farm, this favorite pursuit engrossed his time and thoughts. To this he devoted the energies of an active and well disciplined mind, and that others might share in the fruits of his study and experience, he established in 1833, the monthly publication which has met with so much favor from the public. Success crowned these praise-worthy and philanthropic exertions. The subject of agriculture began to attract more general and enlightened attention. Sister societies sprang up in all directions, zealous in this good work, and among the first acts of their official existence, was usually the election of JESSE BUEL as an honorary member. His fame was soon wafted across the Atlantic, and there, too, similar distinctions were showered upon the man whose life and labors had been attended with such practical benefits to his country and to the world. Thus in 1821, he was elected an honorary member of the Massachusetts Agricultural Society; in 1829, of the Horticultural Society of that state; in 1830, of the Monroe Horticultural Society at Rochester, and of the State Society of Statistiques Universelles at Paris; in 1831, of the Charleston Horticultural Society, in South-Carolina; in 1832, of the Hampshire, Franklin and Hampden Society, in Massachusetts, and of the Hamilton County Agricultural Society, at Cincinnati; in 1833, of the Tennessee Agricultural and Horticultural Societies; in 1834, of the Horticultural Society of the District of Columbia; in 1838, of the Philadelphia Society of Agriculture; and in 1839, of the Albemarle Agricultural Society. In 1824, he was chosen a corresponding member of the London and New-York Horticultural Societies; in 1833, of the Lower Canada Agricultural Society; in 1836, of the Royal and Central Society of Agriculture, at Paris; and in 1838, president of the Horticultural Society of the Valley of the Hudson.

This brief enumeration affords the best evidence of his devotion to the interests of agriculture. Of the consideration in which his counsels and instruction were held, at home and abroad, the rapid increase in the circulation of the Cultivator is satisfactory proof. His own practical skill was fully attested, in the conversion of the barren sand hills on which he settled, into a garden spot of unequalled beauty and fertility. These congenial pursuits brought with them that peace of mind, serenity of temper and kindness of disposition, which made him in so eminent a degree, the firm friend, the kind neighbor, the indulgent parent, and the devoted christian.

But from the scene of his useful labors—from all these tender ties, he has suddenly passed away. Returning springs may give fresh bloom and fragrant blossoms to the plants in his favorite nursery, but the skilful hand and the watchful eye which cherished their earliest growth, are now the tenants of the tomb. The clods of the valley cover his last remains; but though no earthly summer can rekindle, with its genial warmth, their vital spark, a heavenly season shall ere long impart to them a new principle of existence, and the flower which Time destroyed, shall flourish in unfading beauty throughout Eternity.

☞ To our Patrons.

Owing to the great loss sustained by the death of the late Editor and Conductor of the Cultivator, and the general supposition among its supporters and contributors, that the paper would necessarily be discontinued, it is deemed proper to inform our subscribers, that it will be continued through the present year, under the direction of JESSE BUEL, assisted by several practical gentlemen. He hopes, by unremitted exertions, to have it sustain the high standing which it has heretofore acquired, under the superintendence of his deceased father.

If circumstances should prove favorable, the Cultivator will be continued as usual, according to the terms given in the prospectus for Vol. VII. which has already circulated widely. Should it be discontinued at the end of the present year, due notice will be given in one of our last numbers.

We would therefore tender our thanks to the agents and subscribers of the Cultivator, and request their aid in procuring subscriptions and forwarding names as soon as possible, should no notice appear in our next of its discontinuance.

☞ Notice.

All persons indebted to the estate of the late JESSE BUEL deceased, are requested to make immediate payment to the executors of said estate.

CHARLES BUEL,
JESSE BUEL,
AMOS DEAN, } *Executors.*

Albany, October 23, 1839.

☞ To our Correspondents.

Permit us to tender to our numerous correspondents, both old and new, our thanks, for the many useful and instructive communications heretofore received; and we would respectfully invite their co-operation in the future pages of this journal, in any thing that is new or may be useful to the practical farmer and gardener.

☞ Back Volumes.

We would remark, to those who are not in possession of our back volumes, that but few of the first four volumes remain on hand, and those who may wish them, can be supplied by applying soon, either stitched or bound, at the usual price.

Comparison of the Temperature of August and September, 1838 and 1839,

Deduced from observations made at the Albany Academy.

Albany Horticultural Society.

The annual meeting of the Albany Horticultural Society was held on the 18th Sept. at the large room in the *Atheneum Building*. The committee respectfully report the following contributions to the exhibition:

From Walter Elder, gardener for Dr. Wendell, Albany.—15 sorts potatoes, China corn, boquets of flowers, white and red sugar beets, mangel wurtzel, red and white onions, French pumpkin, weight 96 lbs., Spanish pumpkin, weight 90 lbs., kohl rabi, white egg plant, yellow and red tomatoes, 20 sorts hearts' ease.

Philip Henry, Albany—White solid celery, German greens, kohl rabi, case knife pole beans.

Andrew E. Brown, Albany—Large pumpkins, celery, yellow tomatoes.

G. C. Thorburn, New-York—A case containing choice varieties of dahlias.

James Wilson, Albany—Dahlias, green-house plants, varieties of hearts' ease.

J. Buel & Co. Albany Nursery—A beautiful variety of dahlias and other flowers, interwoven in the form of a Castle of Flora: also, a great variety of boquets of flowers.

Theophilus Rossole, Albany—White solid celery, very fine, butter squashes, turnips, blood beets.

Daniel Payne, Albany—Large Roman cabbage, weight 20 lbs., Spanish pumpkins, cocoa nut squashes, ruta bagas, potatoes, cucumbers, variegated corn.

Theodore Allen, Hyde-Park—Salsify or vegetable oyster, purple egg plant and red onions.

Chas. Gilchrist, Albany—Drum-head cabbages, weight 21 lbs. each, egg plant, pears, apples, parsnips, carrots, beets, black cluster grapes.

John Faley, Albany—Large pumpkin, ruta baga, potatoes.

William Buel, Albany—Onions, potatoes, beets, mangel wurtzel, carrots, parsnips, winter squashes, egg plant, ruta bagas, dahlias, peaches, pears, plums, apples.

John W. Smith, Albany—Potatoes and parsnips.

Mr. Benson, Hudson—Sweet water, Isabella grapes, and tomatoes.

Joseph Hall, Arbor Hill, Albany—Pears and quinces.

P. Ashton, Albany—Onions, beets, Lima pole beans, carrots, purple egg plant.

Charles Buel, Albany—Fine tomatoes.

John H. Loucks, Albany—Large pumpkin, weight 110 lbs., cocoa nut squash.

Gen. Dix, Albany—2 varieties pears.

Tho's Ingram—2 varieties grapes.

A. P. Heartt, Troy—Dahlias and egg plants.

Prof. J. W. Jackson, Schenectady—Boquets of flowers and a fine assortment of dahlias.

Thomas Turner, Albany—Plums, grapes, pears, Rohan potatoes, yellow and red tomatoes, beets, cabbages, carrots, 4 varieties corn, ruta baga, largest French pumpkin, weight 112 lbs., celery, squashes, onions, dahlias, and a lot of flowers.

Robert Neely, Albany—Isabella grapes and plums.

Dr. B. P. Staats, Albany—Egg plums.

J. Whalen, Albany—White egg plants, tomatoes, nasturtium in pickle, grapes, dahlias and other flowers.

John B. Hudson, Albany—Purple brocoli, fine carrots, egg plants, long and turnip beets.

Jacob Mayer, Albany—1 large pumpkin.

John E. Lovett, Albany—Magnum bonum and egg plums.

Thomas Dowling, Albany—3 sorts seedling potatoes.

Edward Fortune, Albany—Onions, large water-melons, tomatoes, beets, mangel wurtzel, parsnips, carrots, 7 year pumpkins, crook-neck winter squashes.

Judge Woodworth, Hyde-Park—Onions, carrots, sugar beets, extra large; mangel wurtzel, very large size; purple egg plant, Lima beans, Rohan potatoes, turnips, seedling Victoria potatoes.

C. N. Bement, Albany—Superior white carrots, (a new variety,) long blood beets, mangel wurtzel, tomatoes.

Wm. Bement, Albany—Squashes, parsnips, onions, carrots, mangel wurtzel, very fine.

The committee appointed to award premiums on *Vegetables*, having examined them throughout, and being highly gratified in the extensive show displayed on this occasion, would remark, that many to whom premiums were not awarded, were deserving of them, although the premium list excluded them. They, therefore have awarded the premiums as follows:

Largest pumpkin, weight 112 lbs. to Thos. Turner,	$2 00
Next largest, 110 lbs. to J. H. Loucks,..........	1 00
Two largest heads cabbages, to C. Gilchrist,....	1 00
Two next do. do. to Daniel Payne,..	1 00
Best variety winter squashes, to Edward Fortune,	2 00
Best tomatoes, to Charles Buel,................	1 00
Best fruit of the egg plant, to A. P. Heartt,.....	1 00
Best variety winter potatoes, W. Elder,.........	2 00
Two best heads brocoli, to J. P. Hudson,.........	2 00
Six do. do. celery, Theophilus Rossole,....	1 00
One dozen turnips, for family use, from Judge Woodworth, of Hyde-Park, Dutchess county,.	1 00
One doz. best carrots, for family use, P. Ashton,.	1 00
One doz. do. do. for stock, to C. Gilchrist,..	1 00
One doz. best ruta baga, for stock, to J. Faley,..	1 00
Half doz. best sugar beets, for stock, to Judge Woodworth, of Hyde-Park,.....	1 00
Half doz. best mangel wurtzel, to C. N. Bement,	1 00
Half doz. best beets for family use, to W. Buel, .	1 00
Half doz. best parsnips, for family use, to J. W. Smith,..................................	1 00
Half doz. best salsify or vegetable oyster, to Theo. Allen, of Hyde-Park.,......................	1 00
One doz. best onions, to Edward Fortune, ...	1 00
Half peck best Lima pole beans, to Judge Woodworth,................................	1 00
Half doz. white carrots, (disc. pm.) to C. N. Bement,..................................	1 00
Half doz. yellow tomatoes, (disc. pm.) to T. Booth,	1 00
Three varieties seedling potatoes, (disc. pm.) to Thos. Dowling,.........................	2 00
German greens, (disc. pm.) to P. Henry,.......	1 00
Kobl rabi, (disc. pm.) to P. Henry,.............	1 00
Two Spanish pumpkins, (disc. pm.) to Daniel Payne,................................	1 00

ANDREW E. BROWN,
CHA'S BUEL,
JESSE BUEL, Jr.

The committee appointed to award premiums on *Fruits*, would award the following premiums:

Prem. 1, 2 largest bunches grapes, to J. Whalen,	$5 00
“ 2, Next largest bunches Isabella grapes, to R. Neely,........................	3 00
“ 3, For white Sweet Water grapes, to Mr. Benson, of Hudson,................	2 00
“ 4, 1st on pears, to C. Gilchrist,..........	5 00
“ 5, 2d on pears, to Gen. Dix,............	3 00
“ 6, 1 doz. best variety apples, to Wm. Buel,	5 00
“ 7, 1 doz. next best variety apples, to Cha's Gilchrist,........................	3 00
“ 8, 1 doz. best peaches to Wm. Buel,......	2 00
“ 9, 1 doz. best quinces, to Joseph Hall,....	1 00
“ 10, 4 water-melons, large size, to E. Fortune,	3 00

ISAAC DENNISTON,
R. M. MEIGS,
A. P. HEARTT.

The committee appointed to decide the premiums on *Flowers, &c.* would report that they have awarded the premiums as follows:

1st premium for 25 best dahlias to G. C. Thorburn, New-York,.....................................	$20 00
2d prem. for 25 next best do. to James Wilson,.	15 00
3d prem. for 25 next best do. to J. Buel & Co.,.	10 00
4th prem. for 25 next best do. to Prof. Jackson,.	5 00
5th prem. for 25 next best do. to A. P. Heartt, Troy,..................................	3 00
1st prem. for best design for a centre ornament of a table of flowers, to J. Buel & Co........	5 00
2d prem. for do. do. to Wm. Buel, ...	3 00
1st premium for best boquet of flowers, to W. Elder,..................................	2 00
Premium for greatest variety boquet flowers, to J. Buel & Co..............................	3 00
Premium for best specimen green house plants, to James Wilson,.......................	2 00
Premium for greatest assortment of plants in pots, to J. Whalen,.....................	2 00
Premium for greatest assortment of hearts' ease, to W. Elder,.........................	1 00

ALEXANDER ROSS,
WALTER ELDER,
MARTIN LOWE.

W. THORBURN, *Recording Secretary.*

Acknowledgements.

☞ We acknowledge the receipt of a small box of the Scuppernong Grape, from David White, Esq. of Newby's Bridge, N. C. in fine condition. Fruit very large and highly perfumed.

Also, some fine Quinces, being the product of two small stems, from Lemuel Bassett, Esq. Ovid, Seneca county, N. Y.

CORRESPONDENCE.

On Sea-Weed.

Wheat-Sheaf Farm, Staten Island,
Sept. 16, 1839.

J. BUEL, Esq.—Dear Sir—In your last number, you expressed a wish "to receive a communication from some person familiar with the subject, as to the best mode of preparing sea-weed, and of applying it to the soil." I will not say that I am myself as familiar as I may become on further experience, with the *best* mode; though I have read much of it, and, as attentively as I could, have noticed the practical coincidence of what I have read with the result of my own, and the usual neighboring modes of using it; and I believe I have read essentially all that can be found published, as the result of practice or science, in relation to it.

On turning to page 135 of your same number, among the very excellent observations of Henry R. Madden, Esq. of Edinburgh, we find much of what may be said of it. The sea-weeds of the coasts of Scotland and Ireland are, no doubt, in most respects, similar to ours. Those of our coast, as well as theirs, fall within the general botanical descriptions of *Algæ*, *Fuci*, and *Confervæ*. The similitudes may be traced distinctly in Loudon, where the forms of the entire plants are given.

Though beneficial to a sandy soil of good composition, they have been found, I believe, mostly so to a clay, and well calculated to divide its tenacious or adhesive qualities. They are here usually ploughed in with ordinary manures, after they have become dry and short, through the limited fermentation spontaneously occurring in the sea-weed heap; or after they have been taken thence, more or less dried, used as barnyard or way litter, and thus become incorporated with the manure. On such applications, a free use of the sand of the seashore is also made, intermixed with it, if intended for a clay soil, for several reasons—on account of its saline humidity, and the known attraction for moisture of stony or silicious substances once wet with salt water; of the superior influence of sea sand (in which of course no clay is to be found) above ordinary sand, in amending the composition of a clay soil; on account of the frequent admixture with beach sand, of the granulations or particles of minute sea shells, which the frictional action of the sea on its stones breaks up, and intermixes with it; and also of the operation of the sand on the vegetable substances brought into contact with it by the tread of cattle, and which the acute angles of the sandy pebbles cut and divide, thus accelerating the division of the vegetable matter, and hastening its preparation as a manure.

Sea-weed is also in some instances wind-dried, with little or no fermentation, and thus used for littering horses and cattle, thence finding its way to the manure heap. This practice is well enough *with such surplus* as may be gathered over and above all the farming supply that can be *ploughed in green*, which has ever been considered, *elsewhere than here*, the best course with every description, except that particular species of the *Fuci* class known as the *Zostera marina* (wrack grass,) a long (say two or three feet) flat leaf or spear, a sixteenth of an inch wide, which, in the heap, hangs together in large masses. This is more difficult to decay than the rest; but when short, answers a very useful object, over and above its saline and vegetable properties as an amendator of the texture of clays, in which its detached short pieces will remain visible for many years, dividing its particles. This weed could be readily and expeditiously broken or cut fine by a horse-power operation and machine, similar to the teeth and concave and convex of the common thrasher; and then that too would be best ploughed in green. Its length entire would render the operation of ploughing it in, if at all possible, extremely difficult, and then it would remain undivided by decay too long for free tillage.

Although I, for my own part, entirely disagree with the practice, so often urged, of applying lime, *out of the earth*, to vegetable manures *which have been cured*, or in any way deprived of their succulence or mucilage, or to animal manures or substances in any shape, I would use it freely with all kinds of the sea-weed *while green;* because the lime in that contact will become effectually divested of all its causticity, be thus readily fitted for immediate action on vegetable growth and the soil, and will by its heat overcome the check to fermentation which the saline impregnation of the weed gives to them. If the heap in this state be occasionally wet, it will aid the operation by preventing the excessive heat which the lime would engender.

Lime, as I understand it, not only betters the texture of a clay soil, but its causticity particularly is *destructive of any acidity in it;* and so are the saline parts of sea-weed, as I believe, and propose explaining presently. Perhaps before the causticity of the lime is exhausted by a contact with green vegetable fermentation, or with the soil, but assuredly after, its greatest use is as a stimulant or solvent of the vegetable or animal manures within the soil, and for whatever of pabulum may be requisite to the fibre or rigidity of the plant in sustaining itself against the influence of the winds while attaining its maturity. We have a familiar exemplification of the action of lime on dried vegetable substances, on boards and pickets. The minute splinters left in boards by the teeth of the saw, if soggy or prone to rotting, *whitewashed*, become hard and indurated, and seem checked in their progress to decay by the lime, and the wood is perfectly solid. The same result will be visible if it be applied while yet caustic to dried hay or straw. When lime is brought immediately in contact with animal substances, as with oils, it corrodes and solidifies them; with animal juices, it assails and operates similarly on them, leaving nothing but the mere aqueous fluid; with animal flesh, it checks its putrifactive progress, and as it were petrifies it; with effluvia, it absorbs it. The chemists say, probably with truth, what the lime takes up, or renders *insoluble*, in time it will give back again. This, though true as to a *part* of the substance imbibed, may or *may not* be as to *much of it:* but if even so, it should be recollected that the object of applying manure is to benefit *the first*, as well as the future crops; and the first is dependent entirely, whatever may be the supply put into the soil, upon that portion of the manure which *is immediately soluble;* and if that be held in suspense by the lime, the first crop at least will suffer. This not unfrequently happens with the farmer as to his manure. For the want of an admixture of a portion which is *readily soluble*, his crops come up *ahead of the manure*, and leave him to suppose it not so effectual as he had anticipated; an argument, by the by, for blending manure with the soil before its moisture is assailed and evaporated by the drying influence of the sun, and for that humectation which could be given to it from a reservoir in or about the barnyard for the liquids, and an admixture of it at the moment of taking it out for use. But I am digressing. To return: as to sea-weeds—

I would then *first use them green*, as far as my farming wants might require or permit.

Next. If the supply be sufficiently extensive, (with me it probably is 800 two-ox cartloads annually,) I would use it liberally as litter in every and any shape about my stables, cattle stalls, hogpens, barnyards and muck roads; and that too in opposition to common practice, as far as practicable, *while green;* because, it will be perceived by those who use it, that as (with the wrack grass more visibly) the weeds dry, a white efflorescence of salt gathers upon the surface, which rains wash away, and this salt is one of its most valuable properties. If, while passing from its green state, its succulent, mucilaginous and saline properties escape into the materials for manuring which environ it, the vegetable remains of the weed, divested of its natural juices, will, in escaping, serve as an absorbent of other useful liquid brought in contact with it.

A *third*, and very beneficial mode of using sea-weed, is by *incineration*. Reduced to ashes, its properties become concentrated, and it is both powerful as a manure and useful *commercially*. The carbonate of soda of commerce is obtained by lixiviating the ashes of sea-weed. The best variety is known by the name of *barilla;* an inferior kind, known by the name of *kelp*, is prepared from sea-weeds on the northern shores of Scotland, and may be so anywhere where it is to be found. The purest barilla always contains potassa and soda, and the chlorides of potassium and soda; each of which, though perhaps most profitably employed in the manufacture of soap and glass, would, if applied as a manure to the soil, operate powerfully, and at the same time, from its strong alkaline influence, serve as a solvent to other manuring substances in the soil.

I believe the sea-weed, though best in this point of view if ploughed in green, even in its dry state, a corrective of *the acidity of a soil*. On a field, the soil of which was probably the poorest of my farm, and in which I was preparing to put rye, my carts had deposited some green sea-weed in heaps, with the intention of spreading it before ploughing. A want of time prevented the execution of this purpose in the way proposed, and it was thinned with a fork around the small heaps as it lay, after it had become dry, and ploughed in with the manure for the field. As the crop grew, the grain rose in its growth most visibly within the circumference of the sea-weed thus spread around the heaps, and so much so as to be remarked by all about the farm, and to leave no doubt of its influence. The next year, as the grass came in succeeding the rye, some *sorrel* was seen generally over the field, but *none* was visible within the circumference of the sea-weed; and the grass, in comparison with the rest of the field, was visibly improved, and yet continues so. The sea-weed used on this occasion was of the species familiarly known by the name of *chowder;* a very thin leaf, very aqueous, and prone to rapid decay.

The *principal* kinds in use as a manuring material on my shore, and generally in this vicinity, are the *Zostera marina* above alluded to, (sometimes called, here and in England, *wrack grass;*) the *chowder* also before named, and *rock weed*. There is also occasionally intermixed a dark brown, broad, long and gelatinous leaf, the name of which I do not know.

Sea-weed, particularly the latter and rock weed, are eaten with avidity by swine; and where continual access is had by them to it, will promote their growth and fatten them, though the flesh is far from palatable, if they are not fatted, for two or three months before killing, exclusively on other food better fitted for putting good flesh on them. Some farmers give them little else, up to within that period of fatting time. When thus permitted, however, to range for food on the seashore, they feed exclusively on muscles and such shellfish as they can crush with their teeth, are fond of fish generally, and particularly so of the description known as *horsefeet*.

The wrack-grass sea-weed may also be used as a thatch, and forms a more durable defence against the violent winds and heavy rains than straw.

The latter also is used as a substitute for horse-hair in stuffing matrasses and furniture. For this purpose, it is carefully washed twice in fresh water, and then dried quickly, the intermixture of other sea grasses less fitted for the purpose being picked out.

It is very convenient and effectual for sheltering a manure heap from the drenching of rains, and protecting it from solar heat; for covering plants in gardens, vegetables left in garden grounds, or buried for winter keeping; or for young trees, to protect them from the rigorous frosts of the wintry season, and for a variety of purposes about farming buildings.

An opinion of the practical estimate of its utility may be formed from the fact, that for manuring purposes, it is carted in Ireland to the distance of forty-five miles inland from the seacoast.

Ezra L'Hommedieu, Esq. formerly senator from Suffolk, a very intelligent and skilful agriculturist of his day, in a communication made to the Agricultural Society of this State in 1791, says, "Many farmers are of opinion that one load of sea-weed as a manure, is equal to a load of cowyard manure for raising wheat." And he says, "that within the two years then preceding, he had used more than 200 loads for wheat only, but he did not find it equal by five loads in thirty; that it was found in some respects superior to any other kind for Indian corn, *as it prevents worms and injury from drought;* that the preceding summer, much Indian corn had been cut off by that means, but where the lands were manured by this weed, *the corn was not affected.*"

It may not be amiss here, while quoting from this writer, whose authority is too well remembered to permit a question as to the authenticity of his statements, to notice what he says of the *manure of mud* taken from salt-water creeks and swamps, and in which the weed often grows:—

"Mud from the creeks on Long Island and on the seacoast of some parts of Connecticut, has been made use of as a manure, with *success in some instances*, when *in others no benefit was experienced.* This is owing to their using *two kinds* of mud. In order to determine which is fit for manure, if you run a paddle or a pole into the mud, and it sticks so fast that it is with some difficulty you pull it out, you may determine *that mud unfit for manure,* it being only loam or clay soaked with water; but if your paddle or pole is drawn out easily, the mud is fit for manure. This mud being *taken out in the summer and exposed to the frost during winter*, in the spring, becomes as fine as leached ashes, and is a good manure especially for grass; being spread on poor loamy land, it brings up white clover similar to ashes, though it takes a larger quantity."

To return particularly to sea-weed, and to direct attention to facts, which here have been little if at all noticed. There are many of the *Fuci* class of sea-weed which elsewhere *are*, and here may become *edible.* They are used as condiments by families living near the seacoast in other countries, and by the poor, because in seasons of scarcity they furnish articles of resource as a food.

There are numerous species employed in gardening as manures.

The *Laminaria saccharina* (sweet fucus or sea beet) is sometimes boiled by the common people of England as a pot herb. The Icelanders, Audubon says, boil it in milk to the consistence of pottage, and eat it with a spoon. They are also said to soak it in fresh water, dry it in the sun, and then lay it up in wooden vessels. It soon becomes covered with a white efflorescence of salt, which has a sweetish taste, and in this state they eat it with butter. They also feed their cattle with this species.

The great value of the Iceland and of the Carrigan moss, or *lichen*, in consumptive or pulmonary complaints, is well known every where.

The transparent *edible nests* of the East-Indian swallow, so much in repute at the luxurious tables of the rich in China and the East, are now generally believed to be almost entirely composed of gelatinous fuci, and more especially of the lichenoides. The *plant* also is in high estimation for the table in India.

Of the *Halymenia palmata* (L. dulse,) both the tender stalks and young fronds are eaten fresh from the sea, commonly without any preparation. They are sometimes considered as forming a salad, but more generally are used as a whet. It is said that the inhabitants of the Greek Islands are fond of this species, adding it to ragouts and olios, to which it communicates a red color, and at the same time imparts some of its rich and gelatinous qualities. The dried leaves infused in water exhale an odor somewhat resembling that of sweet violets, and they communicate that flavor to vegetables with which they are mixed. Lightfoot mentions that in the Isle of Skye in Scotland, it is sometimes used in fevers to promote perspiration, being boiled in water with a little butter. It is soft and limber, and does not become rigid in drying, being of a more loose texture than many other sea-weeds.

The *Halymenia edulis* (red dulse) is by many preferred to the *H. palmata*, especially for cooking in the frying pan. Like that species, its smell somewhat resembles sweet violets.

Lmainaria esculenta, (badderlocks or henware.) The midrib, stripped of its membrane, is the part chiefly eaten. In Orkney, the pinnæ are also eaten under the name of *pickles.*

Sphærococcus ciliatus (ciliated dulse,) and *Laminaria digitata* (fingered dulse, sea girdle and hangers,) are sometimes gathered and eaten, like the *Halymenia edulis, palmata,* and other species.

Laminaria digitata. In Scotland, the stem of this species is used for making handles to pruning knives. A pretty thick stem is selected, and cut into pieces about four inches long. Into these, while fresh, the blades are stuck; and as the stem dries, it contracts and hardens, closely and firmly embracing the hilt of the blade. When these handles have become hard and shrivelled, and have been tipped with metal, they are hardly to be distinguished from hart's horn.

Chondria pinnatifida (pepper dulse,) in Scotland, is eaten along with the *Halymenia palmata;* and in Iceland, it is used instead of spice. This species is common to Scotland, Iceland, the Red Sea, and the shores of Egypt.

Floating fucus. The succulent fronds, Turner mentions, are selected and pickled like samphire; and the young shoots are eaten as a salad, seasoned with juice of lemons, pepper and vinegar.

Ulva lactuca, (lettuce leaves or oyster green.) The thin green pellucid membranes, of which this vegetable is composed, are eaten raw as a salad, and esteemed a great delicacy by such as are accustomed to the use of marine vegetables.

Thus, sir, in answer to your wishes, I have given you what I know, or have read of sea-weeds, and their various uses and applications. It may serve to show us that the vegetable kingdom of the ocean, if not as extensive as that of the dry land, has at least its treasures, not only to fertilize the earth, to minister to the weak and the infirm, to feed the poor and the needy, but even to gratify and to satiate the ever-craving and the pampered appetites of the sensualist; that as yet we have not learned fully or perhaps fairly to appreciate them, or this among the many bounties of an ever-good and an all-wise Providence. Yours truly,

W. A. SEELY.

Patent Sausage Cutter.

Fredericktown, Md. Sept. 25th, 1839.

J. Buel—Sir—Please be so kind as to inform the public thro' the columns of your valuable paper, of a newly invented and useful machine, denominated the "Patent Sausage Cutter," the elaborate invention of Mr. A. Henkel, of New-Market, Va. It is erected on a small bench, enclosed by a perforated concave; a crank turns a cylinder, on which are fixed eight revolving knives, which pass through as many upright steel bars, forming a comb. The meat, when cut sufficiently fine, makes its escape through the concave into a vessel set as a reservoir. It manufactures with ease 200 pounds per hour; if pushed and well attended to, much more. The machine is, without difficulty, removed by hand from place to place, to answer the demands of a neighborhood. The knives are readily taken off, when grinding is necessary, and from the neatness and simplicity of the structure, is easily kept in order. To which is added a stuffing machine, which greatly facilitates and expedites that process. We do not hesitate in saying, that every reader of the Cultivator would do well to make further inquiry of its great utility, especially as the price is so moderate as to place it in the reach of the most ordinary circumstances. Price $10. Yours most respectfully,

M. W. WEATHERS.

Proposition for Tow-Path Railway.

Schenectady, September 26, 1839.

Dear Sir—Many years ago, a very aged Englishman, named Johnson, kept a school in this city. He said that he was born in England, but was bred at the *mouth of hell!*—that is, on board of a ship of war.

Those who have dwelt in seaport cities or towns, have had the opportunity of seeing the lives and manners of that class called *old jack sailors.* The term means that class of sailors who do not aspire to office, but they go to sea merely for support of their lives and vices. They are considered to be the most depraved class of men, as to drunkenness, profane swearing and vice.

We who dwell near the Erie canal, have the opportunity of seeing greater depravity in the same vices, in the boys employed to drive the horses used in towing the canal boats. Those boys become abominable blackguards, and swear most profanely. As they are in service at night and in storms, they learn to drink whiskey, and become more wretched than salt-water sailors. Their stopping places, in rum holes, are various; they meet opposition from the same class, and become worse than sailors on board of ship, where their home is limited. The numerous young women and girls also employed in those boats, have the reputation of becoming very degraded, as well as the boatmen. The poor horses too drag out a most severe and destructive service, in being whipped and urged by the driver boys, and are soon destroyed by the cruel service.

Since the canal commissioners will persist in enlarging the canal, instead of using the rivers, I use the freedom of asking you to advise them so to construct the new towpath as to make it the base of a railway, which can most easily be done; and then, by placing rails on it, locomotive engines may run on it and tow all the boats, thereby saving the destruction of the poor horses, and leaving all those numerous driver boys to be employed in some useful calling, and become wholesome citizens, and not worthless and vicious men, as is the present consequence.

Locomotive engines could tow a fleet of boats at the rate of ten or twelve miles an hour. Both the engines and boats could carry lamps, so as to see and travel safely at night, and transport passengers, goods and produce nearly two hundred miles in twenty-four hours, probably from Albany to Buffalo in little more than two days, and thereby reduce the price of freight to a very small sum, probably a barrel of flour to ten or twelve cents from Buffalo to Albany. The saving of time and board to passengers would be so great, as to enable emigrants to remove to the western states at trifling charges. The produce of the *very* far west may be transported through the lakes and canals to the seaboard, at as small expense as formerly they were transported from the Mohawk.

What an immense improvement this would be! It would equal the steam-ships on the ocean for speed and saving of time. It would be truly a new era; and before another century shall pass, men may leave this for the far west, to the Pacific; cross that ocean by steam, and Asia by railways to the Mediterranean, to France and England; and then take the steam-ships as ferry boats to New-York, and thus encompass the globe in a month.

This improvement would save the numerous boys and girls from such exposure to vice, and reserve them for moral service. What a wonderful improvement would be accomplished in the moral, as in the pecuniary world!

If your mind shall accord with mine on this subject, let me ask you to give your advice. I ask this of you, sir, because you have undertaken to instruct and improve all the operations of common life, in agriculture, &c. &c. in your Cultivator.

If the canal commissioners were to furnish the engines and tow all the boats, that may be a source of revenue to the State; and they must do so if engines are employed. Their stations may be at the difficult passes, and where the locks cluster, as the Little-falls, &c.

Most respectfully,

DAVID TOMLINSON.

Judge Buel.

Urate and Poudrette.

New-York, 21st Sept. 1839.

Sir—The New-York Urate and Poudrette Company, finding that gentlemen who had purchased their manures, had been experimenting with the articles, some advisedly and others mistakenly, it became desirable, for many reasons, to learn,

1. On what particular grains or garden vegetables the manure was used, the quantity applied, and the result.
2. To know the precise manner and result of each trial.
3. How the urate and poudrette compare with other manures in their effect, and
4. Generally, whether it was not desirable to the farmer and gardener, to have the contents of sinks and privies made into *inodorous* manures.

In answer to their circular, sent to Mr. Linn, of Schenectady, they have received a letter of so interesting a character, that we ask the publication of it, at as early a day as your arrangements and convenience will permit.

Amended instructions, the result of information received, will be published in a few days, for *gratuitous distribution* among those who have or may wish to use the manures. Yours, &c. A. DEY.

(Copy.)

Schenectady, Sept. 19, 1839.

The N. Y. Urate & Poudrette Co.

Gentlemen—In answer to your "Circular," I would say, that I obtained from your company a barrel of poudrette last spring, intending to test its value as a manure, by a few close and accurate experiments. It came to hand, however, so late in the season, that I was unable to apply it as I intended, or to arrive at results which would in all respects prove the value of the substance as a manure, or the best modes of applying it. I applied it to a variety of vegetables in my garden, and also to a small portion of a field of corn of about five acres, at my farm in the vicinity of this city. The vegetables in my garden have grown with unusual richness and luxuriance, and have most evidently felt the effects of the application. Of the results at my farm, I can speak more satisfactorily, because there I can compare the portion which *has*, with another portion of the same crop, in the same field, which *has not*, received the poudrette. This crop is upon a strong, rich soil, which had been slightly manured in the hill, from the fold-yard, at the time of planting. At the first hoeing, and when the plants by reason of the unfavorable season, were extremely backward, I directed my farmer to apply to a corner of the field, where the crop was the least promising, a handful of poudrette to each hill, covering it at the same time with a thin coat of earth.

This was faithfully done, until the poudrette was consumed. The remainder of the field received, a part the usual dressing of *plaster*, and a part of *ashes*. The plants to which the poudrette was applied, were the first to change colour, throwing off the sickly yellow hue and adopting a deep green. At the period of the second hoeing, the same plants retained not only the appearance of better health, but had obtained greater vigor and more size than any others of the same crop.—They have held the same distinction throughout the season, and it is now plainly visible, although the entire crop is a fair one, that when we come to harvest, we shall gather a greater weight of stalks and more grain from the portion where this manure was applied than from the same space at any other point in the field.

We have certainly no experience proving that the same results could have been reasonably expected from the application of any other of the various manures in common use. With us, plaster has long been considered the grand restorative for this crop, and ashes with many farmers almost a specific; and, indeed, that both substances are very useful as manures on most varieties of soil, is universally conceded. Mills to grind plaster for manuring purposes, are as common throughout the country, as those devoted to grain, and I have seen boats, loaded with *leeched ashes*, toiling their way from the far west, in order to enrich farms on Long-Island. In this experiment, poudrette was applied side by side with plaster and ashes, under circumstances in favor of the latter, and yet they have most indisputably yielded the palm to the former; and all this is not without reason. Heat and moisture are the sources of vegetation: poudrette, if it have it not in itself, will generate more heat and for a longer period than either plaster or ashes, and will absorb and retain more moisture. It seems, also, to decompose inanimate vegetable substances in the soil with which it is mixed, and so to diffuse and incorporate itself with the soil as to change its colour around the plant to which it is applied. Like most other manures, only more sensibly and rapidly, it imparts of its qualities to every substance with which it comes in contact; and by the aid of its own and borrowed heat and moisture, assimilates all to itself, and thus exercises, although applied in most inconsiderable quantities, a certain and immediate influence on vegetation.

I regret that I did not receive the article so as to apply it at the time of planting. I am not sure that the results would have been more successful, and except for the purposes of experiment, I should be content to use it hereafter on most crops, as I have done this season.

Desiccated manures have long been appreciated in Europe. There, one ton of them have been estimated to be equal in fertilizing properties to thirty-six tons of barn-yard manure. At this rate there is a large balance on the score of economy in favor of the former; and when it is remembered that the manures as prepared by your company, are wholly inodorous and may be conveyed in barrels to the most remote parts of the country as commodiously as flour, and at a trifling expense, our agriculturists should be moved by every consideration connected with cleanliness, rural economy, the productiveness of the soil and the right use of the means which Providence places before them, as incitements to industry, to promote the use of substances, which left undisturbed, are worse than useless, scattering, in our large cities and towns disease and death, and which, when submitted to your *alchemy*, spreads health and verdure, and blesses and rewards both the citizen and husbandman.

I shall be pleased to receive your "*Improved instructions for using the manures*," of which you speak, and to know at how early a day this fall, I may order a few barrels for future experiments. Very respectfully yours, &c. A. L. LINN.

Plans of Farm Houses.

Lake C. H. Ia. Sept. 5, 1839.

Hon. J. Buel—My worthy friend—I am much pleased with some of the plans in your last (August) number. That to which you have awarded the premium, certainly is a very convenient house for any family, farmer or other occupation: and I certainly think that that single number of the Cultivator is worth more to every person expecting to build, than all he ever has or ever will pay for the paper.

That the "bump of design and constructiveness," is not possessed by a very large majority of mankind, I think is, or can be fully attested, by viewing the thousands of piles of brick and mortar, and lumber, called dwelling-houses, throughout the country. It seems to me, that if the builders of a great many houses which I have seen, had put all their art and skill in play to make them *in*convenient and *un*comfortable, they could not have succeeded better to their wishes.

But the truth is, that men would rather build a convenient than an inconvenient house, if they knew how; but unfortunately they cannot tell how their own design will suit, until the house is built and tried. And where is a farmer to find good plans of farm buildings? Can you tell, sir? I think not. For in all the architectural designs that ever I have examined, I never have found them. And yours is the first paper that ever I have seen such very useful things published in. I hope you will continue the good work. And I hope every one of your readers, whose *wife* thinks he has a very convenient house, will furnish you at least the ground plan; so that out of a great variety, you might select the best for publication, and out of these certainly every person, by adopting one plan, or parts of several, could always suit his own taste better far than he could do by adopting an original design of his own. I think it will be conceded, that you cannot fill a portion of the Cultivator with more useful matter than such drawings. I hope the additional expense to you will not deter you.

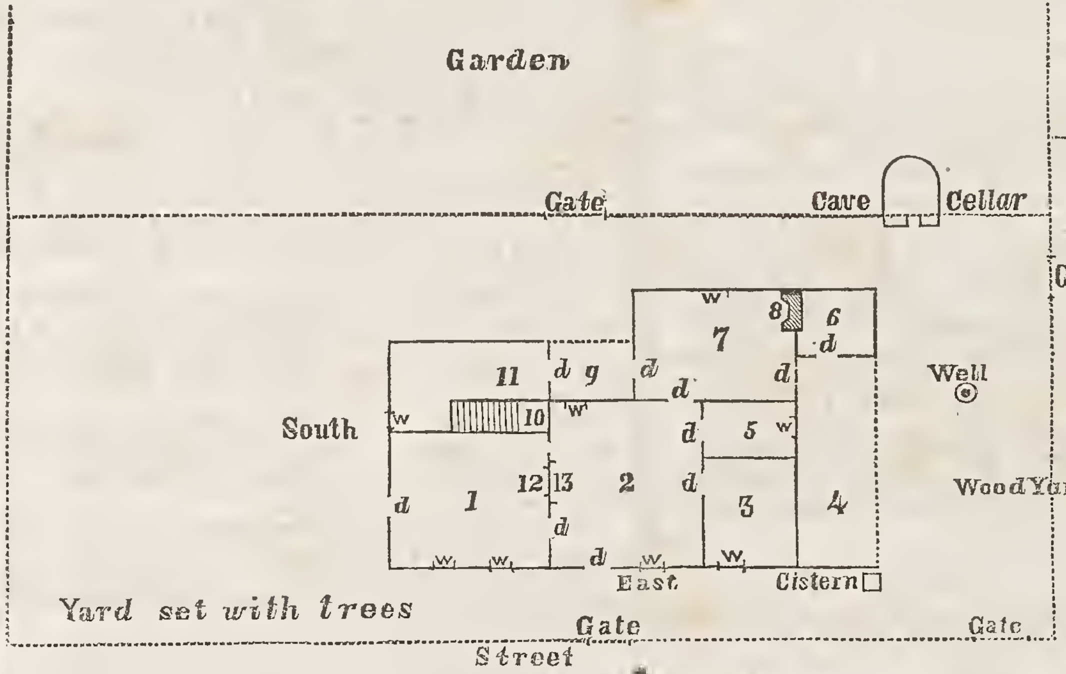
To begin, then, I offer you the ground plan of my own house. It is not of so much consequence to give the elevation, unless where a detailed bill of expense is given.

You have heretofore given a great many excellent plans of out buildings, &c.; that ought also to be continued. No one is fully aware how valuable such plans are, until he commences building himself, and then he sees the want of them. Furnishing farmers with good cheap plans will also tend to prevent another error that some have committed—that is, building a house so big that the whole farm, stock and cash, are sometimes all swallowed up in the house, before it is completed.

It is said that the author of the Declaration of American Independence, swallowed up $70,000 in building a "great house," which has been since sold with 200 acres of land, for $2,500, and now stands a monument of the lack of any proper design in the builder. We all know that the owner died, lacking that independence that he declared all ought to enjoy. This great misshapen mass of materials, was the great cause of his pecuniary embarrassments.

Then let all builders beware, that they do not build a house so big that they cannot live in it, nor so good that when done they cannot use it. I remain, as usual, your friend, SOLON ROBINSON.

Plan of a Western Prairie Cottage.—[Fig. No. 42.]



Explanations.

1. Spare room in the southeast corner of the house, 16 by 16 feet.
2. Common family room, eating room in summer, and cooking room in winter, situated in the centre of the house, so as easily to be kept warm; 15 by 18 feet.
3. Bed-room, 9 by 11 feet.
4. Wood shed in winter and wash shed in summer, 10 by 21 feet.
5. Pantry, 7 by 9 feet.
6. Room for soap, meat, &c. 7 by 10 feet.
7. Kitchen, 12 by 14 feet.
8. Kitchen fire-place.
9. Open passage, to give light to west windows of common room, 6 by 9 feet.
10. Chamber stairs.
11. Buttery, 9 by 16 feet, excepting stairway.
12. Parlor stove.
13. Cooking stove.

d. Doors.
w. Windows.

In the draft, I have sketched the position of the well, cistern, garden, yards, &c. which I consider as a necessary part of the "fixings" about a farmer's house.—Upon our soil, cellars under the house are not admissible; and in my opinion, should never be made under a dwelling-house, only in very dry soils, and then *always kept clean.*

My house is built of hewn logs, but the same plan might be adopted in using any material. It is esteemed a very convenient house, without a foot of waste room.

The south part is a story and a half, the ridge running east and west; the other part one story, the ridge running north and south, and roof extending down over the kitchen. The wood shed is a "lean-to" on the north end.

I am much in favor of one story farm houses. They are much easier for the good woman, and I believe the extra cost of roofing is fully saved in several ways. The frame need not be near as strong for a single story, particularly in a windy situation; and comfort and convenience never should be dispensed with by a farmer for show.

If you think the plan would be of sufficient interest to your readers to warrant its publication, and if I could ever be assured that it added an hour's comfort, or saved a dollar of expense to one of them, I shall be happy to think I have given it. I hope you will be furnished with numerous other plans, so that all tastes may be suited. Your friend, &c.

SOLON ROBINSON.

Farm Dwelling Houses.

Grand Rapids, Kent co. Mich.
20th August, 1839.

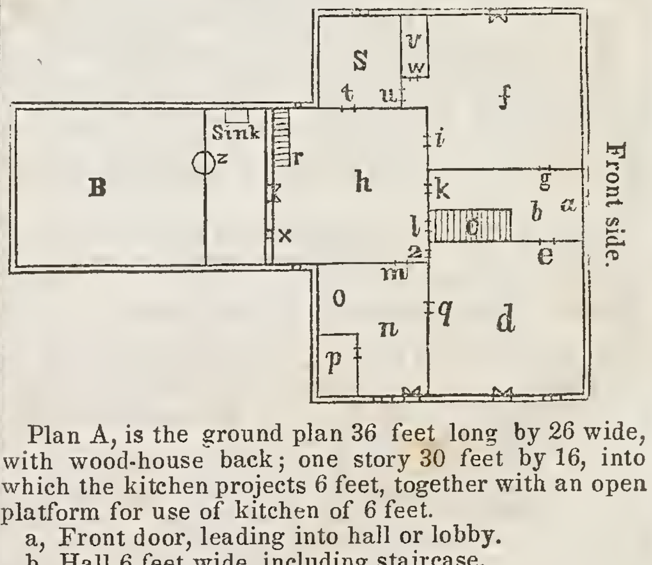
Judge Buel—Sir—Although too late to compete for the premium so liberally offered in your most valuable publication, yet thinking it might (if you deemed it worthy of publicity,) benefit some one else, who thinks as I do in relation to building, I send you the enclosed plan of a dwelling house, to be built of brick, which I commenced making preparations for building the spring past. As I am not a mechanic, but a farmer, unused to drafting, and besides have no other implements than a carpenter's square and compasses and my pen, the drafts will of necessity be rough, but may serve to give an idea of my plan.

In the erection of a dwelling house, there are three things which I consider essential, viz.: First of all, convenience and suitability to the wants of the family who are expected to occupy it. Secondly, economy in the expense of its erection; and lastly, (and by many, perhaps, not thought at all essential,) its beauty or pleasant aspect, which I think ought not to be overlooked. Upon these points I will make one or two remarks. As to the convenience in the arrangement of rooms, the increase of a few additional steps in a part of a house which has to be traversed fifty or one hundred times in a day, would, in the course of the common period of a person's life, amount to a distance of travel that would surprise and astonish us. I have, therefore, endeavored to place those apartments contiguous to each other whose uses have the greatest connexion.

I have always been of the opinion that unnecessary expense in building, is one of the poorest of investments of money, as you receive no profit in return, but are subject to the expense and loss of keeping in repair, and the sure although perhaps slow decay of time. I have, therefore, adapted the size and plan of my house to the wants of that of a common or small farmer, (which I am,) who cultivates and tills from 100 to 125 acres of land, which class, I presume, constitute the largest portion of your subscribers. Many a man has entailed upon himself and family, perplexity and misery by running into debt in the erection of a large and showy "castle," (as some traveller has termed our large country houses,) a portion of which he could neither use nor needed. I always esteem a small well finished and furnished house, preferable to a large unfinished (or finished) empty one.

As to appearance, nothing, I think, which tends to render home delightful and pleasant, which is consistent with convenience and economy, should be neglected. Upon this rule I have endeavored to project my plan.

Plan A.—[Fig. No. 43.]

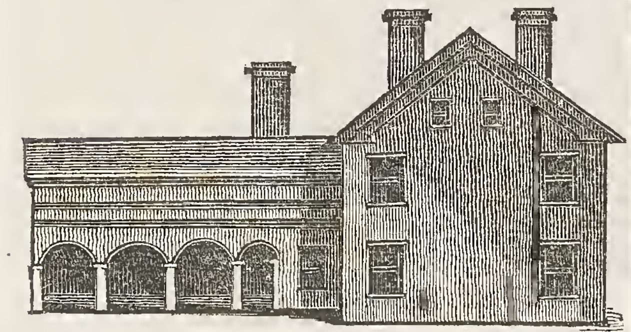


Plan A, is the ground plan 36 feet long by 26 wide, with wood-house back; one story 30 feet by 16, into which the kitchen projects 6 feet, together with an open platform for use of kitchen of 6 feet.

a, Front door, leading into hall or lobby.
b, Hall 6 feet wide, including staircase.
c, The principal staircase.
d, Parlor 16 feet square.
e, Door leading from hall to parlor.
f, Dining room, 16 feet square.

g, Door, leading from dining room to hall.
h, The kitchen, 16 feet square.
i, Door, leading from kitchen to dining room.
k, Door from kitchen to hall.
l, Door to cellar stairs.
2, Door from kitchen to parlor.
m, Door from kitchen to bed-room.
n, Bed-room, 10 feet by 12, including clothes-press, with a small fire-place.
o, Bed recess, size of bed.
p, Clothes press.
q, Door from bed-room to parlor.
r, Back stairs to kitchen and wood-house chamber.
S, Buttery, 7 feet by 8.
t, Door from kitchen to buttery.
u, Door from buttery to dining room.
v, Clothes press.
w, Door from clothes press to dining room.
x, Door from kitchen to platform and wood-house.
y, Platform, open to wood-house, with sink for wash-dish, 6 by 16 feet, &c.
z, Well of water.
|||| Windows.
B, Wood-house.
M, Fire-places.

Plan B.—[Fig. No. 44.]



Plan B, is the elevation view of the end of front part and side view of wood-house. I have thought it unnecessary to draw plans of cellar and chambers. The cellar is intended to be divided in two parts, with windows, and one outside doorway, with steps. One part with fire-place and kettle set in an arch, for coarse kitchen work; cellar wall to be laid in lime mortar; cellar bottom to be floored with hard burned brick, to prevent rats digging under the wall and entering cellar, and no hollow space left for rats or mice, from cellar to garret. The front building to be two stories. The chamber to be divided into four bed-rooms on back side and two rooms with fire-places on front side. As chimneys in brick houses against outside walls, take up very little room and little additional expense, I have prefixed a chimney to each fire-place on ground floor. This will give one to the kitchen, to which is attached the fire-place in cellar; and two to the end of the front part which has the bed-room, and one for dining room at the other end, coming out of front side of roof; another false chimney, for the sake of uniformity of appearance, might be added at trifling expense. This gives the fire-places in the centre of the side of each room.

A house, according to my estimate, of this description, would, at ordinary price of materials and labor, cost about $1,300 dollars, finished in a plain handsome style. Respectfully yours,

J. F. CHUBB.

On Education.

Yates, Orleans County, Sept. 16, 1839.

Hon. J. Buel — Sir — I have come to the conclusion, although personally an entire stranger, of addressing you on the (now much agitated) subject of education; and if business is pressing, you will only need to cast your eye on the signature at the end of this (at least, what I intend shall be,) long communication, to know that its perusal may be dispensed with, till an hour presents in which you can give it your attention without an infringement on your own more important concerns. My apology for thus intruding upon the notice and time of a person of your high standing, will better appear in the importance of my subject, than it could in any words I might utter.

I am well aware that those moral reformations which most materially benefit community at large, originate with, and are most successfully carried on by, those whom Providence has placed high in society. Happy would it be for us as a nation if all great people understood this, and entered as cheerfully into the work for which Infinite Wisdom seems to have designed and fitted them, as do many whom I could name as inhabitants of the truly benevolent city, of which you are both a resident and (forgive merited praise) ornament.

Though I do not belong to the class mentioned above, and am too sensible of my want of talents to think I could do much good if I did, yet since philanthropists have become so deeply engaged in the cultivation of the human intellect, I have felt an almost irrepressible desire to offer my mite of aid; not as one fitted by education to instruct the public—a position I could not maintain — but as possessing some little experience as an *American mother* — a word, a name, sir, as you are already aware, of no small import. I have observed with some regret, that in those eloquent appeals (of late so frequent) to public sentiment, on the subject of education, that a reference to the duty of mothers has not been so often had as I think the public interest requires. There are, indeed, very few who really consider how much the state is dependent on our exertions to cultivate, to refine, and to direct into the proper channels of usefulness, its choicest wealth, the intellect and strength of its junior population. When I reflect on what has been done by some, to educate their families, in this late wilderness of Western New-York, with comparatively no public aid, and then look at the facilities now so liberally held out to parents by the State, I cannot but feel an anxious desire that they may so accept and apply them as shall not only bring comfort and credit to themselves, but enable them also to return to the State "other" with the five talents they are receiving at its hands.

Now, sir, one of the objects of this communication is to suggest to you the idea, that it might be proper to give mothers a more general invitation to enter into the labors of this field of usefulness, than they have yet had. There are many who only need to be reminded of their duty, in order to do it. There is an energy natural to woman, that when once awaked and directed to one object, accomplishes great things: witness the thousands of garments and materials for such, that have been provided and sent off by them to heathen nations within a few years. Now I would not propose to stop these benevolent operations; but I would make them the "mint and cummin of their tithe," that need not be neglected while the "weightier matters" of providing for, of governing, and of instructing their own offspring, must be attended to. I would not be understood to mean that mothers should provide for the temporal support of their children, but for their present and future happiness, by an unremitted attention to all their doings for a number of the first years of their lives. We have divine authority for saying that this duty, when faithfully performed, never fails of being attended with success. I know there would seem to be some exceptions to this rule; but 'tis a great thing to have done our duty. Oh! that parents could be led to realize this while their children are young! How much misery would be avoided, both in time and eternity!

Some years since, I saw a woman at her tub, washing; her two children were in the same room, making cob-houses; a lad some older than her son was visiting there, and at play with them. When they had laid up all their building materials, and not finished their houses, the little girl offered to go and bring more, if her brother and his visitor would not take any of hers in her absence. Both promised faithfully that they would not. As soon as she was out of sight, the visitor proposed that they should each take a few of hers, in order to make their houses the highest; the brother at first refused, but was finally persuaded. The mother was one that (whatever might claim her attention) kept an eye, and an ear open to the doings of her children. She had made up her mind that to "guide the house," meant something more than to keep the clothes clean, though she knew that to be essential. She believed that to have "brought up children," would be to have grown up herself into that perfection of character which the gospel enjoins, and to have led her children up with her. Happy will it be for America, when all its young mothers shall begin with, and adhere to, such principles while rearing their families! She took her seat by her children, and spent the next half hour in obedience to that divine command respecting laws, which says to parents, "thou shalt teach them diligently," &c. Those boys are now young men, both only sons; both their fathers upright, honest men. The visitor has not been under the care of a mother like the one described above; he is now a noted thief, and has been taken up by the public authorities as such. The other is what chivalrous people would call the "soul of honor:" none that know him, would be afraid to trust him with thousands. Now who can say that he would not have been a thief as well as the other? He was persuaded to break his word, and to take what was not his own, and might have been again and again, but for his mother's watchful eye, which was his constant guard until his feet were fairly set in that path from which Infinite Wisdom has said "he will not depart." When I reflect on the incidents of this nature that have come under my own observation, I feel an almost uncontrollable desire to impart the little knowledge I possess to those who are just beginning the fearful task of training immortal beings for everlasting bliss or woe.

'Tis true, yet I know not why, that whatever of reform is started in your city, has a better effect on this part of the State, than if it had originated elsewhere. It was at Albany that, with regard to intemperance, the mighty deep of public opinion was so effectually agitated as to cause its swells to roll with so much force, even o'er this distant land, that almost every distillery was swept from its foundation. Some say, because those first powerful risings of the public mind have subsided, that the temperance cause has died away. I will tell you how it has died away in this little town. At the time of its commencement, there was scarcely one of the beautiful streams with which it is so well watered, but that had one of those public nuisances, a "still," located on it; there was not a church here; the people seemed every day to be growing more and more intemperate and vicious; wives and mothers began to tremble for the fate of their husbands and sons. Ah! and some of them trembled from a cause which even now to write would make my hand tremble. Now our atmosphere is cleansed; the streams of water from which arose such nauseous vapors as distilleries always produce, flow unobstructed and pure into the noble lake to which they are tributaries; we have three large and well-finished churches; and best of all, we have added to the many that may be supposed to have been kept through temperance exertions, some in each church who were called confirmed drunkards, now each Sabbath "sitting clothed and in their right minds," meekly worshipping Him who came to seek and to save that which was lost. The dissipation that seems most prevalent now, is a propensity to waste time. District libraries will prove one of the most effectual remedies that could have been offered for its cure, if the people can be persuaded to apply it; but there are many, very many, not only fathers but mothers, who will not stay at home enough to read and know what they contain. The libraries are a system worthy of New-York and its rulers. But I cannot say what I desire to, on this subject here; therefore I shall accept as a great favor, a sincere opinion expressed by you, whether I had better say any more with my pen at all or not. My husband wished me to consult some of the "learned" of our own county, but as I could not agree with him in thinking there were any superior to himself in literary judgment or taste, I obtained his consent to address a resident of my (once) own Albany county. I thought of D. D. Barnard; of G. Hawley; and indeed I should not hesitate to address that man of powerful mind, William H. Seward, did I not know that the benevolent schemes in which he is already engaged, together with the duties of his station, must fill up his time. Think not it is because we esteem you less, or think your time less usefully employed, that this "lot" of intrusion has fallen upon you. I wish you to tell me, if you think any person in your vicinity would accept an address to parents, scribbled by me, and dissect it, take my ideas, clothe them with their own more eloquent words, and present it to the public. Remember, I speak as a mother that (illiterate though she be) may understand the infantile mind better than man, with all his knowledge of abstruse sciences. Ill health has deprived me of the privilege of laboring as usual in my dairy; so I have turned my attention to writing, and why not as well as though I had been a play-actress and parted with my husband, &c. Respectfully yours,

SELINA TYLER.

On Educating Children at Home.

Schenectady, May 9, 1839.

Friend Buel—In the April number of your Cultivator, under the head "We spread our nets too broad," page 38, the writer says, "The worst place to educate a boy, so far as depends on the advantages of the school, is his native village, where he is wont to lean on parental support, and to remain a mere succor. Send him among strangers, and he will learn *to go alone*, and to depend, for knowledge and character, upon his personal application and good conduct," &c. &c.

These assertions may be plausible to some of your readers; but so far as I have experience, the contrary is the safest course as to the government of children by their parents.

So soon as my children could recognize me, I delighted them by the greatest attention to amuse and please them. This daily attention and fostering care for their comfort and amusement, soon produced their warmest affections and supreme love. They were the most happy when in my care, and were unhappy in my presence, if not in my care and attention. As their knowledge increased and faculties improved, we were extremely careful not to promise the least thing that we did not most rigidly fulfil; so that when they were told any thing, they were certain of its truth, and faithful fulfilment of every promise. Their supreme love and perfect confidence in us was established. If they showed the least disposition to disobey, I told them that I could not love a child who did not love and obey me. This was sufficient for their immediate compliance, for the greatest pain would be the loss of our love, and the birch was never needed nor used. The poet's remark on the influence of love was verified:

> In kindred minds it flourishes alone,
> And claims attachment equal to its own.

We never gave them any *pocket money*, to absorb their thoughts, and to spend at their pleasure. Money was never given them but for specific purposes, although they were always allowed to have free access to it, and were told its objects and uses. They were provided at home with all that was deemed proper, and they had no desire to enter the attracting and debasing cellars and shops for fruit and luxuries, which are the pests of good morals, and ruin of multitudes of otherwise good children.

Before they reached their seventh year, (the age when the human organ of faculty, the brain, is fully developed and matured in volume,) they were manly and womanly enough for that age; for they were spoken to as rational and adult beings, and not in trifling language. They were told that God was the author of them and their kind parents, and all good things; and that their love to him was paramount—next they might love their parents, &c. These are duties not to be looked for from strangers; nor will children receive moral instruction with the same faith from them, as from parents.

When their age increased, and their manners and principles were formed, they travelled without us. They were furnished with money liberally, and were told not to spend money because they had it, but to pay for all useful and honorable wants — to spend nothing in vice nor evil company. They always had enough and to spare, and never asked for a dollar that I had the least hesitancy to furnish, for it never was misused or abused. We are now happy in their reverential and filial obedience and love, and they share in the esteem of society; and the injunction of the wise man, "bring up a child in the way he should go," &c. is fully illustrated in them.

To show the effects of this mode of government, I'll quote one instance in their early years. When their second set of teeth began to appear, I observed that they stood too close, and would crowd some out of regular place. I told them that it would be proper to extract one from each side the upper jaw. They answered that it would hurt. I replied that it would hurt, but that the pain would be short, and the benefit would be ornamental and useful; that if omitted, they would reproach me in riper years for neglect of duty from tenderness, and asked if they would have the teeth taken out on my judgment; they answered in the affirmative. The dentist was sent for, and a beautiful sound tooth extracted from one side; and after a few minutes pause, till the pain was abated, they were asked if they would have one taken from the other side, and it was assented to, and the tooth extracted without further trouble. I then embraced them, and applauded their fortitude and obedience, and they were happy at such result.

I have seen many very fine children, of good and fine minds and manners when they left their parents, ruined, and their manners and morals completely destroyed by being sent from home for education.

I have before heard it said — sending children among strangers makes them manly and womanly. I know it makes them bold; and in some cases they appear in manners to be men and women at twelve or fourteen years, but they are more frequently boys and girls for ever after.

The manners are best formed under parental care: when the first impressions are correct, they will not afterwards be easily rubbed out by improper examples. If they should, through evil communications, be guilty of aberration from duty, their early impressions from kind parents will rise up in their minds, and influence their hearts to repentance and return to duty.

Teachers often make specious promises of useful culture, to influence parents to send their children from home for education and manners; and it often proves useful, particularly to those whose parents cannot, or will not, devote proper care to their children. To such it is often a boon.

When you urge farmers to improve their breeds of sheep, cattle and other farm stock, do you advise them to send them abroad? or to give their best attention to every thing in relation to such stock, if they expect to be successful? And ought not our children to claim so much from us as our cattle?

When children are sent from home for their education, it is not only fourfold more expensive in money and clothing, but often with the loss of good manners, or the acquaintance with evil habits and manners, particularly if they are furnished with plenty of pocket money to use at pleasure while they are not yet qualified to judge of its value and uses, but to be enticed by evil companions to seek opportunities and objects for spending the money merely because they have it.

I can now call to mind many fine children whom I have seen ruined through such means, when they had the promise of fine talents, to become the ornaments of society, had they been prudently educated in early life by examples and precepts of industry and morals. Indeed, I conceive that the most valuable legacy parents leave to children, is a strictly moral and useful education. The want of such education is the direct cause of most of the evils in society. When will the law-makers and conservators of public morals understand and apply these principles, and learn that their true duty is to prevent evils and crimes, rather than the punishment of criminals?

My dear sir, you'll forgive me, I hope, for these observations, as I assure you that I give them to you merely to correct what I conceive to be wrong opinions, and to exhibit a better example. Let parents who have the means, be liberal in establishing good schools at or near home, and employ competent teachers at some additional cost, and save their dear children from exposure to vice, greater expense and ruin, if they believe there is any value in these opinions and experience.

Yours respectfully, ———.

Remark. — If all parents could, and would, imitate the example of our worthy correspondent, it would go far to invalidate our position—that *boys learn best from home to depend upon good habits and good conduct, for reputation and wealth.* There are no teachings so impressive and lasting as parental examples; yet we must take things as they are. Many parents lack either the opportunity, the faculty, or the inclination, to train their sons as they should train them, during their academic years; and where either of these contingencies happen, we are still of the opinion, that the boy is likely to do much better under a good master abroad, than he will do under a slack discipline or misapplied indulgence at home. The master will, or should, be more watchful of the habits of the stranger boy, than of him who is, in other than school hours, under the nominal control of his parents. If the question be tested by the examples of the age, we are inclined to believe that the answer would be in our favor.—*Cond. of Cult.*

Rohan Potatoes—Chinese Tree Corn.

Friendship, Md. October 10th, 1839.

J. Buel, Esq.—I planted two Rohan potatoes, weighing each half a pound, on the 15th March, and dug them the 30th September. The product was one bushel, weighing forty-one and a half lbs. they were planted in drills, 40 inches apart; the pieces about eight inches apart in the drills; the potatoes I cut into 26 pieces, made four short rows, rolled them in lime before planting, hilled them slightly twice, by putting some rich yard manure on them.

A gentleman in this vicinity, planted half an ear of the Chinese Tree Corn, and got about one hundred and fifty good ears from it, and he says it was but partially attended to; he thinks if he had worked it more, the product would have been greater.

I planted a few grains in my garden after the other kind of corn was up, and the tree corn was fit for use the earliest. I remain yours, &c.

ROBERT S. D. JONES.

Chinese Corn.

Albany, Oct. 3d, 1839.

Mr. J. Buel—Dear Sir—I feel called upon to give some explanation respecting the Chinese Corn, I sold the last spring. From a number of communications received from different persons in the northern and western part of this state, the corn has not succeeded at all. It proves a very late variety; I am satisfied this variety of corn will not answer north of this. I have been charged by some correspondents with *intentionally* committing a deception on the public. *This I disclaim.* No one regrets the disappointment more than myself, and I am willing to render every satisfaction in my power. I am not a practical farmer; I was induced to recommend it to our farmers, from the following high recommendations, and sold it in good faith. I will state the experience of three respectable farmers and unprejudiced men, viz:

Mr. Coombs, of *Upper Freehold, N. J.* planted last season, six ears of the Chinese corn, which produced him thirty-two bushels of ears. His general crop of other kinds of corn, last year, was nearly a failure, and is decidedly of opinion that this corn will produce one-third more than any corn grown in that district, and he this seasons rejects all other sorts to plant this on his farm.

Mr. Hendrickson, of the same place, had a great proportion of his corn the last season, destroyed by the cut worm, and replanted his field with the *Chinese Corn* which overtook what was left of the other, and was fully matured some time before corn that was up and well under growing way when the Chinese was planted, and produced the best corn in the field—nor had it any treatment different from the common corn. He this season planted ten acres of it.

Mr. Prentiss, of the same place, planted last season, this same corn, from the 16th to the 21st May. It was perfectly matured and ready for husking on the 1st of September, and on the 16th of September, the whole crop was cut down and stacked. His crop, however, was materially shortened by not then understanding the peculiar branching properties of this variety; notwithstanding this, and the severe drought, his crop was a full average. *Grant Thorburn's* recommendation has been fully before the public.

Under these circumstances, I leave it to the public to say, whether I was not justifiable in recommending it as a new and early variety. Respectfully yours.

WM. THORBURN.

P. S. If it is not asking too much, please add the following, from *E. P. Roberts, Esq.*

[*From the American Farmer.*]

THE CHINESE TREE CORN.

"*John S. Skinner, Esq.*—Dear Sir—I purchased last spring, of Gideon B. Smith, Esq. an ear of the above corn, which had been grown by Mr. Grant Thorburn, of Hallett's Cove, New-York, a part of which I planted in a bed in my garden, and as the success which has attended this experiment may, in part, be owing to the preparation of the ground and mode of culture, it may be as well to detail it.

"The bed was at first highly manured with fresh stable dung, then spaded deep. The ground being thus prepared, I had holes dug four feet apart, about four inches deep, in each of which I dropped two grains of crop, the which I covered with a compost of equal parts of spent ashes and rich mould. When the corn first came up it looked yellow, and supposing that it might be owing to too much acidity being in the ground, I sprinkled over each hill about half a gill of equal parts of air-slaked lime and plaster of Paris, which I mixed with the soil by gently stirring the earth around the plants of corn. I subsequently gave it three thorough weedings and hoeings, taking care each time to make my hoe penetrate deeply into the earth, and each time increasing the size of the hill around the roots. As directed by the notice published by Mr. Thorburn, I have suffered the suckers to remain, and from the luxuriant appearance of my corn, and its prolific yield, I have no doubt he has hit upon the right plan of cultivating it.

"Attracted by its fine appearance, I was induced a day or two since to go into the patch and count the number of ears upon some of the hills. Upon one I counted ten, upon another fourteen, and upon a third, nineteen ears. This, being from two grains of corn planted, must be considered a good yield. This corn is a pearly white, of the flint variety, the ears medium size, and I have no doubt will make an excellent crop of corn. It grows to the ordinary height, yields a great abundance of fodder, and is withal an early corn, having been sufficiently advanced two weeks since, for roasting ears. On strong ground, well manured, with suitable culture, I have no doubt it may be made to yield an average acreable product of a hundred bushels. In the fall I will measure my little patch, and give you a faithful account of its yield in *long ears* as well as *nubbins*, by which you will be able to form a correct idea of its adaptation to field culture.

"By some mistake, two dozen ears of the same corn were pulled some days since for table use, and I have no hesitation in saying that it is equally as sweet as the sugar corn, with this in its favor, that the ears are nearly twice the size.

"Whether this corn originated from a few grains found in a chest of tea, as asserted by Mr. Thorburn, I will not pretend to say; but of this I am certain—it is a most excellent variety, and is worthy of extensive cultivation.

"Should this hastily written note be deemed worthy of insertion, you can give it a place, and oblige your obedient servant, EDWARD P. ROBERTS.

"*Mulberry Grove, Baltimore Co. July* 31, 1839."

Uses of the Sunflower.

Oneida county, Oct. 7th, 1839.

Mr. Editor—Can you or some of your correspondents, inform me, and your subscribers generally, of all the uses of the "Sunflower," and what would be an average yield per acre? &c. &c. and much oblige,

A READER OF THE CULT.

Not having a thorough knowledge of all the uses to which the sunflower is applicable, we copy the following from the London Farmers' Mag.—*Cond.*

"*Cultivation of the Sunflower.*—On inquiring into the use made of this plant, we were given to understand that it is here (in Tartary) raised chiefly for the oil expressed from it. But it is also of use for many other purposes. In the market places of the larger towns we often found the people eating the seeds, which, when boiled in water, taste not unlike the boiled Indian corn eaten by the Turks. In some districts of Russia the seeds are employed with great success in fattening poultry; they are also said to increase the number of eggs more than any other kind of grain. Pheasants and partridges eat them with great avidity, and find the same effects from them as other birds. The dried leaves are given to cattle in place of straw; and the withered stalks are said to produce a considerable quantity of alkali."—*Bremner's Excursions in the Interior of Russia.*

Mammoth Sunflower.

Lake C. H. Ia. September 23, 1839.

J. Buel Esq.—Dear Sir—Enclosed I send you a few seed of what appears to me as a remarkable prolific sunflower, and also as illustrative of the fact, that all of our domestic plants may be greatly improved by care in selecting seed. I have practised for several years past, saving seed from the principal head on the most prolific stalk, and last year I thought I had nearly arrived at the heighth of bearing power, when I had a stalk with forty heads. But the seed which I now send you, is from a stalk with sixty-five seed heads, which grew in my garden the present season. I venture to say there would have been at least ten more heads, but another stalk grew so close on one side that it prevented the branches from spreading in that direction.

Perhaps however, that all this, to you may not be in anywise remarkable or worth notice, but to me, and others who have seen it growing, it is considered so.—It is a well known fact that parsnip and carrot seed, and probably many others of similar branching kind of plants, should only be saved from the principal head. And it seems reasonable to me, that every vegetable may be improved by care in selecting the seed, as easily as I have improved this sunflower.

Many may ask what is the use of raising the sunflower? I reply that it is worth as much or more than corn, and is exceedingly healthy to feed all domestic animals, and particularly hens and horses, and whenever it is raised in sufficient quantities to warrant it, oil mills will be built that will create a good market for the seed. And if no other use than mere ornament was made of it, I should much rather see it growing in waste corners, than useless noxious weeds. I hope you will do me the favor to plant a few of the seeds that I send you, if for no other purpose, that when you look upon their growth, it may be a happy memento to you that there is one other than yourself, that rejoices in every improvement he sees made in the agricultural pursuits of a country, that must soon degenerate below the regard of some of her warmest friends, unless the present awakening spirit of improvement, is made to assume an ever waking watchfulness throughout the whole community.

I am proud to subscribe myself one of your agricultural friends. SOLON ROBINSON.

Mixture of Fruits, Grafting, &c.

J. Buel—Dear Sir—You answered well, all the queries of your correspondent, dated "Michigan, 14 June, '39," except the last query, viz. "Will the trees from the stone of the peach, plum, cherry, apricot, &c. produce fruit the same quality as did the trees on which they grew?"

From my observation, nature is correct and regular, like producing likeness in the vegetable as in the animal kingdom.

The seeds and stones of the fruit of any tree or plant, standing alone, and when the blossoms or the generative organs in them are impregnated from its own genitals, will uniformly produce a progeny of trees and plants, which will produce fruit like the parent tree or plant, lusus naturæ excepted.

We set in the same garden, fruit trees of all sorts, and vegetables to produce seeds of all kinds, near to each other. Those which are in blossom, (their bridal habiliments,) at the same time, and of the same genus, will cast the pollen from their stamina or male organs on the pistils or female organs of their neighbors, and thereby produce hibrids, mules, mulattoes.

I once planted pits of fine yellow gage plums, from a tree in my garden. Two of the trees produced common blue plums, nearly alike; one a large blue plum, tinged with red, late to ripen, and excellent for sweetmeats; and one produced a yellow gage, about half the size of the parent tree, and of inferior quality. The parent tree stood near to blue plum trees, and the progeny were all hibrids.

I planted the pit of an egg plum from a garden of plum trees of various sorts. The egg plum is nearly the size of the hen's egg, yellow, acid, and ripens in September, and probably the best for sweetmeats. The seedling tree produced plums of similar color and shape, of less than half the size of the egg plum, and ripened the first week in August. The flavor was sweet, except near the stone it was acid, like the egg plum.

I reared a peach tree in the same garden. The first season of bearing, the peaches were large, yellow, and very fine; the next season it bore peaches of red blush. An early red peach tree stood a short distance east of the tree in question, and I presume the east wind prevailed when they were in blossom at one time.

Most persons who have planted the sweet boiling corn near to the hard yellow or white corn, and even fifty rods apart, have noticed single kernels of the hard, on the ears of the sweet corn; these kernels appear to be wholly of the hard corn, studded by the side of the shrivelled sweet corn. So all the other trees and vegetables mix in the blossoms, and produce new varieties. Some are inferior; but we are now enjoying some most delicious new varieties of plums, of much larger sizes and of superior flavor: they are hibrids.

Apples are improved in the same way, or are rendered inferior. The flavor of choice apples grafted on the stocks of *sweet* apple trees, is more mild than the flavor of those grafted on stocks bearing *sour* apples.

If you plant potatoes of one color and kind, which were produced near to those of another color, you often collect both colors and sorts from the hill planted of the one color only.*

I have said enough to those who observe the works of nature, to establish the proof of the cause of hibrids and varieties in fruits.

It is often asked, which is the best method to transplant trees? The most successful mode that I have practised, has been, to open a hole sufficiently wide to permit the roots to extend in their natural position, not to be cramped. Fill the hole full around the tree with dry and loose earth, such as of onion beds in the garden, and of good quality; then dash in a pail of water, and shake the tree gently. The water converts the fine earth to liquid mud in the hole around the tree; the mud will cling to all the roots; the water will soon sink below, leaving the mass of mud compact around the roots, and no cavities of air. Then fill up the hole again with dry earth, and press it gently down.

If the tree is set in dry earth, filled in, it leaves vacancies of air under the roots, and they starve and perish. Many fine trees are lost in transplanting, by saving the handsome top. The roots of the newly set tree cannot receive immediate nourishment from the loose ground, sufficient to support a large top; and while the roots are connecting with the ground, the top dies from want of nourishment.

It is best to graft trees immediately after transplanting them, because you then cut off the top to insert the graft, and leave but little of the top, that the scion may not be starved. The roots will support and nourish the trunk and scion, if the season is not too dry. Trees are saved by watering the first year, in dry seasons, when they would perish with a large top, which is apt to be retained if the tree has been grafted in the nursery.

Some persons have great objections to cut off the top of trees. It depends on the treatment, whether it injures the tree. To be perfect, (and we should attempt perfection in all things,) the grafting salve should always follow the pruning knife. The most economical and effectual mode of applying the salve is to get a small furnace of sheet iron, of the size and shape of a lump of refined sugar, such as the tinsmiths use for heating their soldering irons. Let a small hole of about an inch and a half in diameter be cut out near the bottom, with a slide door piece of the iron to cover it, large enough to be fastened above with a rivet, so as to slide the door open when heat is wanted, and to cover the hole and shut out the draft when the draft should be stopped. Get a tin or sheet-iron vessel made, of the shape and size of a tin quart measure, to fit into the top of the furnace, with a flange at top to prevent it from sinking below the top of the furnace, and a wire handle or bail to lift it out by. On the side of the furnace opposite the door, let a small tube be added, or a groove to serve as a chimney for draft, to make the charcoal burn in the furnace, to melt the grafting salve in the quart or pint cup, according to the quantity wanted for few or many trees. When the grafting salve is melted to a liquid state only, you may dip in a painter's brush and apply it to the wound, like painting, when the limb is cut off. It being in a liquid state and warm, it will adhere to the raw wood, and shut out the caustic air, like as balsam of fir does in a cut on the finger, applied before the air inflames it; it heals by what is called first intention, or natural growth of the flesh on the finger, or the bark on the tree.

Some persons prune trees in the month of March, because they then have leisure time. The best time to prune in this climate is about the first of June, or after the juices or blood of the tree is in full and steady circulation. Then, if covered with the salve as above advised, it will exclude the caustic air and rains from injuring the wood and lips of the wound, where the bark must begin to furnish a covering, like the skin on animals, over the raw place. If trimmed in March, or left without a cover of salve or soft cowdung, or something to exclude the air and rains, the wind will dry the raw wood, it will shrink and crack, and let in rain and produce a rot, which will always remain in the trunk to the age of a century, and often cause the trunk to become hollow and die.

Scions should be cut in February or March, here; or before the buds have swelled by the vernal heat, while in their state of hibernation. Place the scions on the damp ground of a cold cellar bottom, cover them with wet straw, and place a piece of board on to keep them wet and from warm air. The scions should be thus kept till about June, and then grafted. If the grafting is performed early, as in the warm days of April, and the cold winds from the west and northwest blow within a few days thereafter, they will check the supply of sap in the stock, starve the scion, dry it, and it will perish.

The safest time to graft, is after the season is advanced so far that the stock receives a full and regular supply of circulation of blood, to nourish the scion. After the scion has begun to receive nutriment from the stock, it will soon starve and perish if the nourishment is stopped by cold and dry winds.

Young plants and animals are prone to life. If scions or plants are once wakened from their state of hibernation by supply of nutriment, they will easily perish if that supply is discontinued. So young animals, if food be withheld from their birth, they will not perish for a long time; but after they have once fed, and become dependent on nourishment through the stomach and alimentary canal, they will not long exist if deprived of nourishment. The house fly, and other dormant insects and animals, will hibernate and lay all winter without food, and waken in the spring in vigor and health, but soon perish of hunger if deprived of food while in active life.

Some fishes also follow this course. The mackerel becomes blind in winter, and sleeps in the deep till spring, when the scales fall from their eyes, and they come on the shoals to feed. The black fish, or rock fish of the rocky places in the sea, hibernate at the commencement of winter, and sleep till spring, like the bear, racoon and squirrel, &c.

It is best to set young forest trees a mere bare pole, except a few buds of the size of a knitting-needle. The roots will supply the trunk the first year, and feed the aftergrowth, and the top will grow regular and handsome. If a small limb be left on one side, it will take the growth, and the tree will be one-sided. Large trees of any size may be transplanted, if the earth is permitted to freeze around the roots, after digging a trench around beyond the small roots, so that the tree may be set in a hole prepared.

Make salve for grafting, of one part tallow, two parts beeswax and three parts rosin, to be melted together, and thrown into water; and while warm, well worked by pulling and doubling and pulling, &c. It should be so hard as not to run off by heat of the sun, and not so hard as not to yield to the growth of the scion.

Most respectfully,
DAVID TOMLINSON.

Schenectady, September 5, 1839.

Queries.

Essex Co. Va. Oct. 1, 1839.

The subscriber will thank Judge Buel, or any of his contributors, to answer the following inquiries, if they can do it by stating the results of actual and careful experiments. He asks not for mere opinion, pro or con, —having quite enough of his own, and some to spare, —relative to the matters in regard to which he is anxiously desirous to be informed by some of his brethren, who have more experience than himself.

1st. What are the indications (if any,) by which we can certainly know, when the beet, the mangel wurtzel, the carrot and the parsnip come to maturity?

2d. Does either, or all lose any portion of their nutritive properties by remaining in the ground after that time?

3d. Which (if either,) loses most?

4th. In digging them up, is there any difference as regards their preservation, between cutting and twisting off their tops?

5th. Is it not best to feed away those tops in their green state, rather than to steam them?

6th. What is the most profitable distance at which to cultivate beets and mangel wurtzel?

7th. Which is preferable in cultivating any or all of these root crops,—to manure broad-cast on a level surface, or to manure in furrows and sow on the ridges formed over them,—the quantity of manure being the same in both cases?

The subscriber believes that he has some good reasons for doubting the propriety of the common practice in most, if not all of these cases, and would therefore be glad to receive any information which experienced root culturists can give him, since the culture of roots is becoming daily more important throughout the Atlantic states.

In stating that he has no wish to receive mere opinions in reply, he begs not to be understood as objecting to them altogether, for he is entertained by many which he reads in your paper, while some are well calculated to excite inquiry, if not to convey instruction. To all such, he always pays due attention; but he must avail himself of this occasion to say, that if that portion of the contributors to the Cultivator who are so fond of indulging themselves in this easy kind of writing, would give us more facts,—more results of experiments fairly and accurately made,—and less speculation, they would greatly increase the value of your excellent paper, to all who seek improvement in the theory and practice of husbandry. J. M. GARNETT.

The Season, Crops, Mode of Culture, &c.

Salem, Indiana, 9th Mo. 17th, 1839.

We have had an extreme drought in this part of the west, which has extended from the middle to the eastern part of this state, a part of Ohio, and the central part of Kentucky, which has affected our corn and root crops very much. We shall not realize more than half a crop of corn or potatoes, and our crop of turnips, &c. will be almost a total failure, though we are not much in that line yet. I planted a few ruta bagas last year; I did not much more than save seed; this year I planted about one-quarter of an acre, early in last month; they have but lately come up, having lain in the ground about six weeks, without moisture sufficient to make them vegetate. One of my neighbors, who takes the Cultivator, put in one-quarter of an acre early in the sixth month, in a piece of new ground, and notwithstanding the drought, his bids fair to be pretty good.

We had an abundant crop of wheat and oats; grass light.

I have not used any other plough in my corn crop this season, since I planted, than the cultivator, and a double shovel, which is similar. I kept them pretty constantly moving, and I find that my corn is much better than my neighbors.

I rented a field on my place to a man, and he worked it well in his way; that is, with a Carey or bull plough, which makes a large open furrow, and there is only a lane between his and the piece that I tended, and his is on much the best and freshest ground, and mine is the best corn.

I should like to see more frequent remarks of the conductor of the Cultivator, as I rely much more on his than the opinions of his correspondents; yet I am well pleased with the Cultivator, and think that I have been and expect my neighbors much benefitted by its excellency in the art of farming. I remain thy friend,

MICAH NEWBY.

Lunar Influence.

Newby's Bridge, N. C. 9th month 26th, 1839.

Respected Friend J. Buel—I have many times heard the remark, that pork killed on the increase of the moon was better, or would waste less in cooking than that killed on the old or decrease of the moon; and that corn, beans, peas, &c. would grow and yield better, planted on the increase, and potatoes, turnips, parsnips, &c. were best planted on the decrease of the moon.—These things I have usually disregarded in my practice.

In the tenth number of the 5th volume of the Cultivator, Calvin Butler states his experience in regard to pork, and on speaking of the subject, among some of my neighbors, one observed, he did not care about the moon, when he killed his pork; if the wind blew from the south at the time, his meat would not shrink in cooking? Another said "if his pigs were littered on the increase of the moon, it was of no consequence to him about the moon or wind when he killed them."

Among my hogs intended for my own use the present year, were two of the same litter so near alike in colour, shape, size, and fatness, that it was not easy to see any difference. I therefore determined to try the matter for my own satisfaction. Accordingly, on the 28th of the 12th month, two or three days before the full moon, one of them was killed with the rest of my hogs, which weighed 103 pounds, was cut up in the usual manner, marked No. 1, and salted away. Two weeks afterwards the other was killed, weighing 118 pounds, was cut up and salted as the other was and marked No. 2. About two months afterwards a ham, No 1, weighing 11½ pounds was boiled whole, except the shank, which lost three ounces; two weeks after that, a ham, No 2, weighing 13 pounds, was boiled as the first, which lost four ounces in cooking. About the first of the summer, the other ham, No. 2, was boiled and lost four ounces; the other No. 1, was used without knowing when, consequently without weighing. Since that time two of the middlings have been used in my family, alternately boiling a piece of one and then the other. I have not, neither has my family, been able to discover any difference in the shrinking of the meat: it was evident that the last killed was the fattest, and if there was any difference in the flavor of the meat it certainly was in favor of that last killed.

I may here remark that in North Carolina and Virginia, hogs designed to make bacon for our families' use, is preferred that will weigh 100 to 150 pounds each, consequently the greater number of hogs when killed, does not exceed the latter weight. Our method of curing bacon is, after the hogs are cold, take off the head and separate the ribs from the back bone, with an axe, split the hog open, take out the back bone, and flakes; then divide each side into three parts, ham, shoulder, and middling; trim the joints smooth; then to each ham or shoulder, put a tea spoon full of salt petre, rub it on the flesh side; then salt it well with common salt, made pretty fine, and pack it away in casks or in bulk:—in a week or ten days overhaul it, arrange the salt on the meat again, and if necessary add more salt, and lay it away again; in two or three weeks after, wash off the salt and hang it up and smoke it a brown colour, and let it remain hanging until used or taken to market.

---

* Doubted by the Conductor.

If I can have hogs of about a year old, with small bone well covered with meat and fat, managed as above, whether the moon be old or new, or the wind blow from the north or south, when they are killed, I have confidence that I shall have good bacon, and that it will not waste much in cooking. Thy friend,

DAVID WHITE.

EXTRACTS.

On the Preservation of the Fruits of the Earth by Secluding them from the Action of Air, Water, and Heat.

[*From Chaptal's Chemistry applied to Agriculture.*]

The atmospheric air coming in contact with fruits deprives them of their carbon and forms carbonic acid.

Fruits exposed to the solvent action of water suffer decomposition by having the affinity existing between their constituent principles weakened, and at length destroyed.

Heat dilates the particles of bodies, and thus diminishes the forces of cohesion and attraction, and favors the admission of air and water.

The combined action of these three agents produces very speedy decomposition: the effect produced by any one of them is slower, and the results different. So that in order to preserve fruits from decomposition it is necessary to guard them from the power of these three destroyers.

In several European countries, particularly in the north, roots of all kinds are preserved merely by secluding them entirely from air, heat and water; this is done by digging deep ditches in a dry soil upon a spot a little elevated, and depositing in them the roots, which are afterwards covered over with a layer of earth of sufficient thickness to prevent them from suffering by the frost; over the whole is then laid a bed of straw, broom or fern, in order to protect them from rain and from the water of melting snows, which might filtrate through into the pit.

Roots, to keep well, must have their surfaces entirely free from moisture before being thus buried.

The roots have in themselves a preserving principle, which does not exist in a dead plant or one that has terminated its period of vegetation: they have as yet lived but a portion of their vegetable life; thay have not formed the seeds, which secure the continuance of their species; and to fulfil this great design of nature they profit by every circumstance, which can favor and confirm their vegetation; but when placed for a time beyond the action of air, water, and heat, their organs remain at rest till again excited by the presence of these powerful agents.

As dead bodies do not retain this animating principle, the energies of which are only suspended in roots, grains, &c. during the winter, so they suffer decomposition, though less rapidly, from the contact of air, heat, and water.

In the way of which I have just spoken, beets, carrots, potatoes, and many other vegetables may be preserved uninjured till summer.

A very simple method of preserving them at least free from decomposition, is, to heap them up in piles upon a very dry soil, and then to cover them upon all sides with straw enough to protect them from rain and frost: in England, this is esteemed the best method of keeping turnips.

Vegetables may likewise be preserved by heaping them up in barns to the height of five or six feet, care being taken to cover them well with straw or hay at the commencement of the severe cold weather. Should the roots in these heaps begin to vegetate, they must be removed, and thus their farther development checked.

Thomas Dallas has published some very important observations* upon the modes of treating potatoes which have been affected by the frost. With us such potatoes are rejected, as being unfit either for food or for furnishing fecula. The able agriculturist above mentioned considers them in three different states; 1st, when they are slightly touched by the frost; 2d, when the outer portion of their substance is frozen; and 3d, when they are frozen throughout.

In the first case he finds that nothing more is necessary, than to sprinkle the roots with lime to absorb the water formed under the skin, which would speedily occasion their complete decomposition. In the second instance he causes the potatoes to be pared and thrown for some hours into water slightly salted. When the potatoes are completely frozen, he finds them to yield, upon distillation, a spirituous liquor resembling the best rum, and affording much more alcohol, and that of a better quality, than can be procured from the roots before freezing.

The preservation of grains has always been an object of much consideration both to governments and agriculturists, and it is a peculiarly interesting one, because bread forms so large a portion of the nourishment of Europeans, and because the scarcity and high price of it have been the cause or the pretext for popular discontents and insurrections.

The art of preserving grains unchanged, besides obviating this evil, presents the additional advantage to the agriculturists of enabling him to make a good harvest, compensate for a bad one, by maintaining the price of bread stuff at a rate suitable alike for the consumer and the producer; and thus avoiding those periodical successions of high and low prices, of abundance or scarcity, which disturb social order, and give rise to excesses prejudicial to all.

It appears that the people of the most ancient times preserved their grains uninjured through several years, merely by secluding them entirely from the action of air and moisture.

The Chinese have from time immemorial preserved their grains in pits, which they call *teon:* these ditches are either hewn out in rocks, free from chinks and humidity, or what is still better, they are dug in a firm, dry soil. If there be any danger of humidity about the pits, they are lined with straw, or wood is burned in them to harden and dry the earth. The grain is not put into the pits till some months after the harvest, nor till it has been well dried in the sun; it is then covered over with mats made of the chaff of the grain or of straw, and this again by a bed of earth well beaten down that it may not be penetrated by water.

Varro, Columella, and Pliny inform us, that the ancients proserved their grain in ditches hollowed out of rocks or dug in the earth, the sides of them being lined with straw. Quintius Curtius relates, that the army of Alexander experienced great privation upon the banks of the Oxus, because the inhabitants of the country preserved their corn in subterranean pits, the situation of which was known only to those who dug them.*

I have several times had occasion to visit in Amboise what are called Cæsar's granaries, and from examining the place, I think there can be no doubt that it was intended for the preservation of grain. About thirty feet above the level of the waters of the Loire, there are dug in a dry and solid calcareous rock, deep and broad excavations arranged in three stages separated from each other by vaults. Behind the first excavations, there are formed others, and separated from them by a wall of rock six or seven feet thick, and within these are built, of brick and mortar, circular granaries of about fifteen feet in diameter: the upper part of the granaries is contracted, and the aperture, which is that by which they are filled, is covered over by a stone: the grain is taken from them through a hopper placed at the bottom. To avoid all dampness, the space contained between the walls of the granaries and those of the rock is filled with fine and very dry sand from the Loire. A gallery formed also in the rock communicates on one side with the granaries, and on the other with a staircase cut in the rock, which conducts directly to the banks of the river. It would seem that the excavations served as magazines of stores for daily consumption, and the granaries for reserved supplies. It is difficult to conceive of any arrangement more suitable for preserving grain, or of a situation more favorable for obtaining or for transporting it.

In some warm and dry countries, it has been customary from time immemorial to preserve grain, with less precaution certainly than in the granaries above described, but in situations where it could be kept for six or seven years. Prosper Alpinus relates, that not far from Cairo there was a high wall built, enclosing a spot of ground of about two miles in circumference, which was filled every six or seven years with heaps of wheat: he adds, that the abundant dews of night softened the outer portions of the grain and caused it to germinate but that in a short time the sun dried the young shoots, which then formed a hard covering to the mass, and did not permit either air or moisture to penetrate it. In a similar manner individuals may preserve their grain upon floors in the open air, merely by covering the heaps of it with mats.

In the Basilicata, according to the report of Intieri,† the farmers form their corn into heaps upon the borders of the sea; these are soon covered, in consequence of of the rains, with a strong vegetation, which forms over them a layer impermeable by air or water. * * *

The grains which are consumed in Algiers and Tunis, or which are exported thence, are, after having been well dried in the sun, deposited in trenches cut in the rocks, and having their sides lined with straw. The Count of Lasteyrie has found the same mode followed in Malta, Sicily, Spain, and Italy. There are even some countries where the governments have caused trenches to be constructed, in which the cultivators of lands might deposit their harvest till a favorable season for selling them.

In order to secure a perfect preservation of the grain in trenches, it is necessary to make use of certain precautions, without which the entire loss of it must be hazarded: the means of security are as follows.

1st. The grain should never be put into trenches till it is perfectly dry; it must therefore be first exposed to the sun for several days, and during that time be often turned, that every part of it may become equally dry.

2d. In constructing the trenches, choice must be made of a dry soil, or a rock free from chinks, that there may be no danger either from dampness or the filtration of water. The walls of the trenches may be made with such cement as the Romans used in the construction of their aqueducts; this is composed merely of lime and pebbles; the walls of these aqueducts were raised in frames, and the surface of them carefully polished; I have visited the remains of some of them in various parts of France, and have found them everywhere present the same appearance; I am convinced that this cement is impenetrable by water, and of a solidity more than sufficient for constructing the sides of trenches.‡

3d. The third precaution consists in excluding the air completely; if this fluid should gain admittance, it must necessarily convey in at the same time moisture and oxygen, the two principles of germination; the presence of air will likewise favor the existence and multiplication of insects: whilst if the trench be full of grain and well closed, all the air which it contains will be changed into carbonic acid, (as I have explained in speaking of the action of air upon fruits,) and the insects will remain torpid. This last assertion is, as we shall shortly see, supported by the results of the experiments which have been made by the Board of Provisions of War, for the purpose of ascertaining the best mode of preserving grain.

But the construction of these trenches, as it involves some expense, and requires much care, will be for a long time rejected by mere farmers. However advantageous this arrangement may be, it belongs entirely to public authorities, great cities and governments, to set an example of the use of it, by withdrawing from circulation, during years of abundant harvests, large quantities of corn to be deposited in trenches and preserved against years of scarcity. Much has been written within a few years, upon the best methods of preserving grain; but all those that have been proposed were founded upon the same principles.

The Board of Provisions of War, under the direction of Count Déjean, has performed a series of well directed experiments, from which excellent results have been obtained: the apparatus used in them consisted of lead receivers hermetically sealed and having all their joinings soldered. Meal and grain full of weevils were enclosed in three receivers; when these were opened, at the end of a year, it was found that no injury had been done by the weevils; they were all either dead or in a state of torpor. In one of the receivers there was found a collection of grains adhering to each other in a mass about as large as a middling sized apple; this arose from the entrance of air and moisture through a hole the size of a pin, accidentally left unsoldered in one of the joints.

The elder M. Ternaux caused trenches to be formed and filled with Corn in the beautiful field of Saint Arven; in order to be sure of the preservation of the grain, he caused the trenches to be opened from year to year, and the results were always satisfactory.

Corn, well dried and guarded from air and moisture, may be preserved in the ear for a long time, and it is a well-known fact that in some agricultural countries the sheaves are formed into stacks which are taken down either for consumption or the market, at those times when the laborers upon the farm can be employed only in threshing in a barn.

Instead of constructing trenches of stone without the farm buildings, there might be built, within them, bins of stone, of a size proportioned to the produce of the farm, and with the openings covered in such a manner as to exclude the air. The same purpose may be answered by chests and tubs of wood having their outsides covered with a thick coat of oil paint. The great earthen jars in which oil is kept at the south, are likewise very good for keeping grain in.

Either of these methods is preferable to that of storing grain in such granaries as are commonly used, since the utmost care will not entirely protect it from moisture, insects, mice, &c. nor will it often remain in them unchanged beyond three or four years.

Corn which is housed without being thoroughly dried, or which is stored in a damp place, acquires a musty smell and taste, which render it unfit for the customary uses: but as this alteration affects only the outer covering, and not the substance of the kernel, it may be easily removed by throwing upon the grain double its weight of boiling water, carefully stirring the mass till the water becomes cold. The spoiled kernels which swim upon the top, must then be removed, the water poured off, and the grain spread to dry. M. Peschier preferred employing for this purpose boiling water rendered slightly alkaline, and afterwards washing the grain in pure water.*

When corn has been heated or injured in a perceptible manner, the vegeto-animal portion is almost always changed; in this case the farina is not susceptible of a good fermentation, and the bread made from it is unwholesome: such grain is fit only for the manufactory of starch.

The modes of preserving vegetable juices and other articles of food deserve also much attention.

The substances of which I shall now speak present the alimentary principle so mixed with, or dissolved in the aqueous fluid, as to render them exceedingly susceptible of alteration and decomposition. It is not sufficient to seclude these from the air, since they contain for the most part within themselves those principles of fermentation, which, acting upon each other, produce decomposition.

Seclusion from the air alone will not preserve these substances; the nature of some of the fermentative principles must be changed; and for effecting this I would recommend the preserving process made use of by M. Appert and confirmed by numberless experiments. I shall here only make mention of the mode of preservation; as the work of M. Appert is before the public, it may be consulted in regard to the necessary details respecting each operation.†

* Des Fosses propres à la Conservation des Grains; par M. le comte de Lasteyrie.

† Della Perfetta Conservazione del Grano; 4to. p. 12.

‡ The mode of building may be used which the Count of Lasteyrie has proposed in his work entitled, Des Fosses pour la Conservation des Grains.

* Annales de Chimie et de Physique, tome VI. p. 87.

† Le Livre de tous les Ménages, on L'Art de conserver pendant plusieurs a nées toutes les Substances Animales et Végétales. 1811, 2e édition; par M. Appert.

The process consists,

1st. In putting up, in glass jars or bottles, those solid or liquid substances which are to be preserved.

2d. In corking the bottles carefully.

3d. In placing these vessels upright in a boiler filled with cold water, as high as the ring of the bottles.

4th. In causing the water to boil, and continuing the ebullition for a longer or shorter time, according to the nature of the substance contained in the vessels.

In this process we see that nothing more is required than a boiler and some bottles or jars; it is one that may be practised in the smallest domestic establishment. In order however to avoid accidents and insure success, certain precautions in each part of the process are necessary: the principal of these, especially those that are indispensable, I shall here point out.

The choice of bottles is a matter of some consequence: the form of the champaigne bottles is the best, and as the glass of these is of a more uniform thickness than that of others, it is generally better annealed; these bottles then should be preferred, particularly if they have proved their soundness by having resisted the action of the compressed air contained in foaming wine.

Too much care cannot be taken in the choice of corks; only the superfine should be used, and these should be free from defects. The length of the corks should be at least eighteen or twenty lines, and the diameter a little greater than that of the mouth of the bottles, into which they must be forced by blows of a mallet.

The bottles must be filled within three inches of the ring; the corks selected for them must be softened a little in water; in stopping a bottle, put the small end of the cork into the mouth of the bottle, and force it in as far as possible with the hand; then wrap the bottle in a towel, and, holding the neck of it firmly in the left hand, drive the cork in by repeated blows with a mallet; a few lines of the length of the cork must be left beyond the mouth of the bottle to receive the wire or twine with which it is to be secured. Each bottle is then to be put into a bag of strong linen, which will cover it to the cork, and placed in a boiler filled with water to the rings of the bottles. The boiler is to be covered, and over the lid must be placed a damp linen cloth, to secure the retention of the heat. The apparatus being thus prepared, the water may be heated to boiling, and continued in that state as long as the nature of the substance to be preserved requires.

When the fire has been removed from the fire-place a quarter of an hour, the water must be drawn off by means of a siphon, or of a stop-cock placed near the bottom of the boiler; the cover must not be removed to take out the bottles till fifteen minutes after the water has been drawn off.*

When meat or other solid food is to be preserved, wide mouthed bottles or jars may be used in the same manner as the narrow-necked bottles mentioned above.—Good gravy of meat, and beef three-quarters cooked, when prepared according to the foregoing directions, have been found as good after being eighteen months at sea, as when first put up. Attention must be paid in putting up solid articles in bottles, to pack them closely, in order that as little air as possible may interpose between the pieces. *Consommés,* strong decoctions,† and jellies of meat containing all those portions of it most nourishing to man, may be thus preserved uninjured for a long time.

Before milk is put into bottles for keeping, it should be evaporated in a water or vapor bath, and the scum which forms upon the top carefully removed; half an hour before evaporation is completed, there should be mixed with every pint of the reduced milk, the yolk of an egg well beaten. After being thoroughly cooled the milk must be put into bottles, and corked tightly to undergo the second scalding. Milk preserved in this way has been found at the end of two years to be unchanged, and to afford butter and butter-milk the same as if new. It is not however pretended, that it preserves all the qualities of new milk; it almost always has a peculiar odor and taste, but such as it is, it forms an agreeable and a valuable article for sea stores for long voyages.

Cream evaporated one fifth-part and put into bottles after having had the skin coagulated upon the surface removed from it, and then subjected to a second scalding for an hour, has not been sensibly altered at the end of two years.

Those vegetables of which so much use is made in all families, may be preserved in the same manner; they are, however, boiled a shorter time, and some of them must previously undergo a degree of preparation. For instance, in preserving asparagus it is necessay, after having washed it, to plunge it first into boiling and then into cold water, to deprive it of its acrid taste; it afterwards receives but a slight scalding.

To preserve the color of the small bush-beans, bottles filled with them are plunged into very cold water where they remain for an hour; they are then drawn out, corked, wired, and scalded for an hour. Artichokes, after having had boiling water poured over them, are washed in cold water, drained, and scalded in the bottles for an hour. Cauliflowers are prepared in the same way as artichokes, excepting that they are boiled but half an hour. Legumes in general, prepared and seasoned, and put into bottles when three-quarters cooked, will keep very well with being scalded twenty minutes.

Antiscorbutic plants, and the juices which are extracted from all fruits and vegetables require only to be scalded. When juices are to be kept, they should be carefully strained and clarified; plants require to be well washed, picked, and dried, and to be crowded into the bottles. When any of these preparations are made use of, they should be dressed in such a manner as to give them the appearance of those prepared daily in our kitchens.

Those articles that have been cooked before being put into bottles, only require to be heated.

The strong decoctions will need the addition of nothing but water to become good broth.

The jellies of beef, veal, mutton, chickens, &c. when diluted with water, and seasoned with salt, make excellent soups.

The legumes must be washed upon being taken from the bottles, and then prepared as if fresh.

The juices may be appropriated as usual, either for food, drink, or medicine.

I shall close this article by observing, that some bodies are preserved from destruction, and guarded from the attacks of insects, and the action of air and water, by means of a coat of varnish laid upon the surface of them; this practice has become very common, and when the varnish is applied to bodies well dried, and does not scale off, it preserves them a long time. Oil paints and tar produce the same effect.

The custom of preserving eggs by immersing them in lime water has lately been introduced into Paris; the shell of the egg thus immersed becomes covered with a thin coat of lime, which preserves its contents unchanged.

[* The translator of this work has preserved the most delicate fruit by a process somewhat similar to the one here described, but with one pretty important difference. As the preservation of the fruit seems to depend wholly upon the exclusion of the air, which would not be effected by corking the bottles before exposing them to heat, and as the bottles would be in great danger of being burst by the expansion of the air contained not only in the fruits themselves but in the interstices which must unavoidably occur between them, the above method appears to be an imperfect one; she therefore takes the liberty of inserting in this note the process which she has used successfully, and particularly as she has found fruit thus preserved exceedingly grateful in sickness at those seasons of the year when no fresh fruit could be procured, and when that which was done with sugar was neither suitable nor agreeable.

Pick carefully over the fruit to be bottled so as to take only such as is perfectly sound, and put it in bottles having wide mouths with closely fitting corks, shake the fruit well down so as to leave as little space unoccupied as possible in the bottles; when they are quite full, set them uncorked into a boiler of cold water over the fire, raise the temperature of the water as quickly as possible to the boiling point, and as soon as ebullition takes place, put the corks into the bottles, and remove them from the boiler; some ready melted cement, such as is commonly used for closing bottles, must be immediately applied over the corks, and the fruit having been freed by the heat from the air contained within the bottles will thus be protected from the action of the external air, and may be preserved fresh for many months.—Tr.]

† Answering to "portable soups."

Memoir on the Classification of Soils.*

BY M. DE GASPARIN.

[*From the Edinburgh New Philosophical Journal.*]

It is undoubtedly a matter of surprise that in an art which engages the attention of so many distinguished men,—which is the great basis of national prosperity, and which excites so many different energies, a name has not yet been devised for the expression of the different qualities of earth which form the theatre and principal material in all its operations. Attempts have been made to confer upon it a nomenclature, one of the first requirements of a rising science; but before success can be obtained, it must make the same attainments that the other natural sciences have recently done. For the discovery of the appropriate characters of his classification, the author has directed a particular share of attention to Chemistry and Natural Philosophy, to Microscopic Observation, Geology, and Botany; and the soils have been analyzed, experimented upon, and observed in relation to all these sciences. As it is impossible, in this place, to enter at length upon the consideration of these laborious researches, we must confine ourselves to the citation of some of the facts which result from the investigation. 1st, The author points out the small quantity of carbonate of lime which is sufficient to change the character of soils. It is known that the five or six per cent of this substance which is supplied by marling, produces very remarkable effects, whilst the one-hundreth part which is contained in the soil of Lille, as analyzed by M. Berthier, likewise sensibly affects its nature and vegetative power. Lime gradually disappears from soils, being changed into a bicarbonate. The enclosure of *la grande Chartreuse,* which is formed of the debris of rocks which contain lime, does not now furnish a single particle of this earth. 2d, The carbonate of magnesia modifies soils in the same way as the carbonate of lime. This earth is contained in great quantities in the soils of the valley of the Nile; and those of *Bas-Languedoc* often furnish from eight to thirty-three per cent. 3d, It has often been attempted to ascertain the characters which distinguish those soils in which gypsum produces an effect upon vegetables, and those in which it has none; but hitherto without success. The author has ascertained that gypsum has no action upon recent alluvial soils, and that it produces a beneficial effect upon all more ancient soils, beginning with the diluvian. 4th, He has found sal-ammoniac in all the clays belonging to the vegetable stratum of soils.—This observation shows the importance of clay as a magazine of the materials which favor vegetation. 5th, If by washing we separate into several portions the coarser and finer parts of earth, we find that the tenacity of such soil is in proportion to the quantity of the latter kind, except in a small number of cases. 6th, Upon examination with the microscope, it is ascertained that these exceptions are owing to a coating of ferruginous clay which adheres to the surfaces of the mineral particles,—that washing separates it with difficulty, and that it serves as a cement, forcibly agglutinating, and increasing the tenacity of the whole.

On the Principles of the Classification of Soils.

If we study the objects which we find in nature, that we may know them as they really are in themselves, under all the relations of their organization and their properties, it is in their innermost existence,—in the relation of their parts,—in their resemblances and dissimilarities, that we must seek for the means of grouping them together, without any regard to the circumstances which are foreign to their peculiar and proper existence.

It is thus that Jussieu established the several families of plants, Cuvier those of animals, and M. Beudant his orders of minerals. Each of their groups collects together the beings or the substances which bear the closest resemblance to each other, under all the appreciable relations of their organization or of their texture, but without intermingling therewith any idea concerning their utility, which could only be considered as foreign to the subject; and this forms pure natural history.

But if we regard it in another point of view, if it be not the being or the substance in itself which we wish to study, but only such and such a property of the object, the classification then ceases to be a natural method or arrangement, and becomes a common classification.—Accordingly, when we would study plants in an agricultural point of view, the consideration of families should not mislead us; as it would be impossible to establish any one agricultural principle which would be common to an entire family. That of the Gramineæ, for example, presents us with oats, wheat, rice, and the sugar-cane, which require different cultures, and serve for very different purposes. Besides, the number of plants which are the objects of agricultural interest is small, and were we to conduct a course of agriculture, according to the order of families, we should have only shreds of these families, which, detached from their natural alliances, would exhibit nothing but disorder, so soon as the intermediate links were withdrawn which maintain the order of their connection. What, then, under these circumstances, is to be done? The answer is clear,—we must combine together the plants whose kind of cultivation has the greatest analogy, and we should thus have, for example, 1st, trees; 2d, the trees and shrubs which yield an annual crop (such as fruit-trees, mulberries, vines); 3d, the feculent grains (wheat, oats, buck-wheat, &c.); 4th, the plants with oily seeds (the poppy, colza); 5th, the plants which yield fodder (lucerne, spurry, ryegrass); 6th, plants used in weaving (lint, hemp); 7th, plants used in dyeing (dyer's woad or glastum); 8th, the oleraceous plants (pot-herbs, spinage, chiccory); 9th, roots (beet, carrot, madder,) &c. &c. According to this method, classes are formed in which the natural affinities of plants are often broken, but which, on the other hand, present another kind of affinities, such as proceed from their mode of culture. They are, therefore, natural classes in relation to farming, whilst they cease to be so considered in the light of natural history. This is a method which has been followed in regard to medical substances, articles of food, &c. Chemistry itself classes natural bodies in a manner different from what mineralogy does, because the view it takes of them is different. Thus, not only the practical arts, but the pure sciences themselves, modify classification, according to the object they have in view, without at all changing the natural relations of bodies; they determine that one of their properties which ought to predominate in the order they impose.

In agronomy, therefore, it is no longer simple substances, or bodies in their individual condition, such as a plant, or crystal, we have to examine; but it is mixtures of many of these substances, of which we form individuals only by abstraction, as we do in rocks, formed as they are by the union of many minerals. But this intellectual operation which regards the habitual union of several substances and forms from them one collective being, is much more natural in practice, than that which would consist in considering in granite only the three minerals which compose it, without regarding their aggregation; and still more than that which, decomposing these minerals into their last chemical elements, would remove granite from mineralogy, and view it only as a compound of oxygen, silicium, aluminium, potassium, magnesium, and iron. It is thus too with soils, although some may present only a single mineral element, as for example, silex; and though others, as much oftener happens, contain many, and these associated with vegetable and animal debris. We can consider abstractedly each of these mixtures as a pulverized rock, and deal with it, as we do with rocks, in forming a systematic whole.

After having thus demonstrated that both reason and custom authorize us to propose a classification of soils with a special relation to agriculture, we may examine; 1st, what the characters are which agriculturists should examine in soils; 2d, the relative value of each of these characters; and, 3d, their application to classification.

---

* Report of a communication presented to the French Academy of Sciences. This Memoir is the first part of a work upon Agronomy, which is that branch of the science of agriculture which has for its object the study of soils; what belongs to their susceptibility of cultivation, and to their relative value, is reserved for another publication, the author confining himself on the present occasion to the consideration of their classification.

§ I. *The Characters of Soils in relation to Agriculture.*

When an agriculturist devotes himself to the investigation of a soil, it is a matter of indifference to him whether it is composed of alumina or silica, or whether these substances are in the state of quartz or felspar, or that by their aggregation they form the debris of granite, or finally, that they belong to primitive, transition, or alluvial formations: what he requires, is to know what kind of plants the soil will produce with the greatest advantage, the trouble it will require to put it in a state of culture, the manuring it will need, the quantity of this manure it will yield to the plant, and the portion it will retain in its own substance, these are its agrcultural characters,—those which adapt it to the objects of agronomy, and which shed light on his researches.

What we have already said of the composition and properties of soils, demonstrates that certain of their scientific elements have a relation to the properties which are inquired after by agriculture. Thus, as to the nature of the crops which may be expected from different soils, those which contain carbonates of lime and magnesia are eminently qualified to produce wheats and leguminous crops; the siliceous clay-lands are the soils peculiarly adapted to forests; the siliceous are proper for plants which vegetate in winter, as rye, &c.; mould favors the vegetation of those pot-herbs which are cultivated for the stems, leaves, &c. As regards the facility or difficulty of working soils, those that are siliceous are easily dressed, as well as those which have an organic origin; whilst calcareous and clayey present great differences in this respect, according to the diversity of their composition. Finally, sandy and calcareous soils require frequent manuring, and this addition they decompose to the immediate profit of the plants, whilst clayey ones retain the manure, may have the process of manuring postponed to greater intervals, and receiving at the same time a larger quantity of manure. Diluvian soils admit of improvement with gypsum, and siliceous clays with marl; whilst lands rich in organic matters require the dung of animals to facilitate and promote the decomposition of the mould.

Thus, we find in the mineralogical characters we have examined in detail, whether physical or geological, certain relations with the agricultural characters. There are whole groups of soils whose natural characters answer to those agricultural characters, and reproduce properties which are common to them all. After having recognized and distinguished them, we must next recognise those of them which from their importance and generality will most naturally form the primary groups.

§ II. *Relative Value of Characters.*

For the appreciating of the relative value of the agricultural characters which we have enumerated, it is necessary to discover which amongst them is the most indispensable, and those whose absence would be most hurtful to agriculture; the degree of their importance and necessity will then indicate the relative subdivisions.

The appropriation of lands to the different kinds of cultivation seems to possess these qualities in the highest degree; and here, in fact, must begin every kind of agricultural improvement. It is only after having destined a particular soil to an appropriate culture, that we can begin to consider the labor and improvement it requires. These labors and improvements will be without an object and a bearing, if we are still ignorant of the plant to which they would be useful. And, moreover, this investigation of the appropriation of soils to particular cultures, is connected with the most natural classification, in a mineralogical point of view; it breaks the smallest number of affinities, and consequently renders the determination of soils more easy and more satisfactory.

The labor required for bringing the soil into good working condition, is also a matter of great importance; for if the appropriation of soils decides the phytological or botanical part of the question as to cultivation, this other consideration bears on the question of economy. It modifies the plan of regulating the soils which might be determined on from the first consideration taken by itself: it has also a very decided influence upon the choice of the means to be employed in overcoming the resistance upon the number and kind of animals, and upon the implements to be procured. But were this circumstance taken as the primary basis of the classification, we should then break all the natural affinities of soils; for all the mineralogical kinds are, in a greater or less degree, susceptible of tenacity. Besides, it is evident that this greater or less degree of facility in working soils, dissociated from their capability of producing the most useful plants, is a quality of very little value; that it is of no great moment, for example, that we can easily labor a dry sand, and a rich marl only with difficulty; and that, in short, in the examination of an estate, it is the character of the plants we inquire about, before we calculate the expense of their production.

As to improvements, and the necessary means of enriching vegetation, they are without doubt the sign and consummation of good farming; but their use is much less frequent than it ought to be: most lands are cultivated without their aid; and we cannot, therefore, consider an exception which, we trust, will soon cease to be one, in the light of a character so general as the preceding.

Upon the whole, therefore, we establish the subordination of the agricultural characters which ought to be considered in soils, in the following method:—1st, The appropriation of soil to plants; 2d, the tenacity of the ground; and 3d, the aptitude of the soil to receive certain kinds of manures or improvements.

§ III. *Primary Classification of Soils after their appropriation to particular cultures.*

The Cerealia are every where throughout Europe the basis of rural operations. They succeed more or less in all the soils which supply them with a firm support, and which at the same time allow the air to penetrate to their roots; ranging from sandy soils which do not contain less than 80-100 of sandy or rocky materials, to stiff clays, provided that the soils do not contain 2-100 of sea-salt, or any sulphate of iron. The soils or pure mould are also excluded from this kind of cultivation, from the defective cohesion of their elements, and their frequent change of volume. Allowing for these exceptions, there are three principal groups of soils. 1st, the saliferous; 2d, the sandy, which contain even as much as 8-10 of sand or of rock; and, 3d, organic soils, which contain ¼ of mould. This division, it should be remarked, agrees not only with the results of the mineralogical study of the soil, but also with its tenacity; and hence it is perfectly natural.

There remains, moreover, a great number of soils in which wheat thrives, when they contain, besides, a sufficient quantity of organic matter; but they are not all equally favorable. For its successful cultivation, those which contain only silex and clay must have lime added, a principle without which they will scarcely yield any return. As soon as this is supplied, their product immediately increases in a remarkable manner, to the extent of a fourth, a third, and even a half. The vegetation of the Cerealia, therefore, indicates a grouping which subdivides lands into soils containing carbonates (of lime or of magnesia, the latter supplying the place of the former), and into silico-argillaceous, or clayey soils, which do not contain carbonate of lime or of magnesia. Hence the agricultural principle is, in its turn, in agreement with the principle drawn from improvements, and no longer with that of tenacity; for in these two classes of lands, we find that, according to the proportion of the mineral principles which they contain the soils possess a different degree of tenacity.

Other kinds of culture confirm this view. Fruit trees thrive admirably in siliceous and clayey lands, and these are generally the soils of forests; leguminous plants prefer soils in which there is a carbonate, and then they appear naturally; and it is only in the same circumstances that dye-plants afford vivid colours.

We have already remarked, that we cannot avail ourselves of the characters which are drawn from the tenacity of the soil, without destroying the groups which we had previously formed. We can, however, reserve them for the formation of secondary groups, which will subdivide the primary classes. It will be the same thing with those which are derived from the property which gypsum possesses of rendering certain soils eminently productive of vegetables; but we have seen that it is the geological position of soils, more than their composition, which has hitherto contribted to designate them. But each of our groups contains earths of different geological formations, so that we should run the risk of breaking them up if we were to introduce this consideration into the formation of our primary groups; and, upon the principle above insisted upon, this character will rank after the one derived from tenacity.

These principles being allowed, we now proceed to the exposition of the classification of soils, which they snpply.

FIRST DIVISION.—*Soils having a Mineral Basis.*

Character.—These soils do not lose a fourth of their weight upon heating them till they emit no more vapor.

FIRST CLASS.—*Saliferous Soils.*

Character.—Soils with a salt or styptic taste, containing at least 0.005 parts of hydrochlorate of soda, or sulphate of iron.

1*st, Saline Soils.*—Water digested with these soils, gives a precipitate with nitrate of silver.

2d, Vitriolic Soils.—Hydrocyanate of potass gives a white precipitate with the ferruginous salt which is contained in the water digested with this soil.

SECOND CLASS.—*Siliceous Soils.*

Characters.—Producing no effervescence with acids; affording by levigation at least 0.70 for their *premier lot.**

THIRD CLASS.—*Clays.*

Characters.—Not yielding effervescence with acids, and affording by levigation less than 0.70 of the first portion

FOURTH CLASS.—*Calcareous and Magnesian Soils.*

Characters.—Producing effervescence with acids; lime, or magnesia, or both, are found in the solution.

FIRST SUB-ORDER.—*Chalks.*

Characters.—Leaving no residue after the action of the acid, or only leaving a siliceous residue less than 0.50.

SECOND SUB-ORDER.—*Sands.*

Character.—This soil contains at least 0.50 part of siliceous or calcareous sand, which does not escape from a sieve whose division or holes are the 0.02 of an English inch in diameter.

THIRD SUB-ORDER.—*Clays.*

Character.—This soil leaves a residue of 0.50 of clay after effervescence and levigation.

FOURTH SUB-ORDER.—*Marls.*

Character.—After the action of acid, a clay remains whose levigation does not remove more than 0.10 of free silcx.

First Section.—Calcareous Marls.

Character.—Having at least 0.50 of carbonate of lime or magnesia in their composition.

Second Section.—Argillaceous Marls.

Character.—Having at least 0.50 of clay.

FIFTH SUB-ORDER.—*Loams.*

Character.—After the action of acid, the residuum presents clay and free silica, which, by their levigation, give each more than 0.10 of the weight of the soil.

SECOND DIVISION.—*Soils with an Organic Base.*

Character.—Losing at least a fiftieth of their weight when they are heated till they do not emit more vapor.

FIRST CLASS.—*Fresh Mould.*

Character.—The water in which this mould is digested or boiled does not redden litmus paper.

SECOND CLASS.—*Acid Mould.*

Character.—The water in which this mould is digested or boiled reddens litmus paper.

In each of these classes, the *genera* are formed by the consideration of the tenacity of the soil, which is so very important an element in its characters.

The work concludes by laying down rules for the description of *species,* and with *examples* of all the methods of description. In reading these, we at once perceive how precise an idea of soils is conveyed in a manner that cannot be misunderstood by any agriculturist.—The possibility of transmitting these clear and pointed descriptions to a distance, follows as a matter of course; and we shall in this manner be freed from all that vagueness which has been so long a just cause of complaint.

"If I have succeeded (concludes the author) in what I have proposed in writing this book, the study of agricultural treatises will be greatly facilitated; the different methods which are followed in distant countries will no longer appear so marvellous, and will become more intelligible; we shall comprehend better the considerations which limit or extend the several cultures, and a necessary link being established between the science of agriculture and other natural sciences, it will become more intelligible to all, and will more readily profit by the progress of all the other branches of human knowledge."

Upon the Respiration of Plants.*

BY MESSRS. EDWARDS AND COLIN.

In the interesting science of vegetable physiology few or no facts are to be found more beautiful than those connected with the respiration of plants. The same remark, however, can by no means be made concerning the theory which combines these facts, and undertakes to explain them. In fact, we have always experienced the greatest difficulty in admitting this theory, whether considered in relation to the respiration of the seed or of the leaves: and, in truth, scarcely any other phenomenon has been recognized in the respiration of the seed than the disengagement of carbonic acid. This is usually explained by the combination of the oxygen of the air with the carbon of the seed. According to this view, the seed is supposed to be affected only by the atmosphere; the influence of water in this vital act of plants is considered either as absolutely nothing, or is limited to that of preparation and promotion, and it is held in no way to contribute to the production of the gas which is disengaged. This, then, is the first difficulty respecting this theory of germination which presents itself; and those which occur in regard to the explanation of the respiration of the leaves are still more serious. During the night, it is said carbonic acid is disengaged, whilst during the day it is absorbed, and oxygen appears under the direct rays of the sun. Here, then, are the facts, and here the explanation which is afforded: the absorbed carbonic acid must be decomposed by the plant, which again must appropriate the carbon, and disengage the oxygen.

But this capability of decomposing carbonic acid is conferring upon the plant a power which it is very difficult to admit; and it is very seldom found in the mineral kingdom, where the very great simplicity of the composition of bodies increases their decomposing power, and where the much greater number of elements, scattered throughout the different compounds of this kingdom, renders it probable that we should discover some endowed with this property. Finally, water, according to this supposition, is of little or no use in this action, although it is absolutely required for plants, and we are perfectly ignorant of the part it plays. These are some of the considerations which have induced us to undertake the examination of this function in plants; to which we were also conducted by some facts brought under our notice in agricultural physiology, to which we shall solicit attention in the sequel.

Up to the present period, experiments upon the respiration of seeds have always been made in the air; or if made in water, the phenomena which occurred in the liquid have been limited to the explication of what took place in the air; the gas disengaged in the liquid has not been examined, and consequently its proportion has not been determined. What follows is an account of what we have done in relation to this point, and which has yielded very extraordinary results. Our operations were conducted on a great scale, that the effects of the experiments might be more distinctly brought out.

---

* The "*premier lot*" comprehends the large particles which are deposited when the water in which the earth is dissolved, is strongly shaken.

* Read to the Academy of Sciences, Nov. 1838. From Annales des Sciences Naturelles, for December, 1838.

On this account, we selected for our operations a great ball-shaped bottle with a narrow neck, capable of containing six or eight pints of water. We filled this bottle, and introduced forty garden beans of a large size, without any fissure in the husk, or any other defect whatever. To this great bottle we adapted a bent tube, also filled with water, which finally was introduced into a receiver full of the same liquid.

By this arrangement, the beans were in contact only with water, and with the air which it contained, air which, under the circumstances, could not be removed; and this was one of those important circumstances which led to all the success of the experiments. The first phenomenon which presented itself was the disengagement of air-bubbles, which proceeded from the beans. These bubbles were at first very minute, insensibly they increased in size, and in the space of twenty-four hours they were very conspicuous.

This evolution of gas was itself a very extraordinary circumstance which had not previously been pointed out, and which scarcely seemed to agree with the received ideas upon germination; still less with the supposition that this disengagement proceeded from air contained in the beans; which idea soon became wholly improbable from the unceasing continuance of the disengagement of the gas, and to such an extent that it could not by possibility be attributed to this cause.

First of all, it is certain that the gas came from the beans themselves, for before we introduced them into the apparatus, we were careful to put them in water and shake them well, thereby detaching all the air which was attached to their surface. For a long time after they were plunged into the water of the bottle, no gas was seen to issue from their surface, and it made its appearance only by degrees. Besides, on other occasions when the beans were cut through, we have seen it proceed from the parenchymatous substance itself.—Many of the beans were actually made to float by the air-bubbles which adhered to them, and fell to the bottom so soon as the bubbles burst.

After a period, which was never less than four days, we put an end to the experiment. Our first care was to weigh the beans, that we might thereby determine the quantity of water which they had absorbed, and we invariably found that it exceeded their own weight. In reality, the mean weight of the beans employed was 1,540 grains (avoirdupois), and the moisture which swelled them amounted to about 1,848 grains.

The most essential point of all in this investigation was to certify that the beans were alive, and in a state of germination; for it is evident that it is a condition which must indispensably be established, that the disengagement of the gas which is effected in the water is the result of a natural and normal function.

When taken out of the liquid, some of the beans had a chink opposite to the point where the radical is situate; but there were only three or four in this condition.

If the beans were living, the function was normal; so we planted them, that we might have an apportunity of comparing them with the same number of other beans which had not been subjected to any experiment, and we had the pleasure to see them spring up quite as well as these. The best method, however, of conducting the experiment is to keep them in moistened paper between two plates. Next day, during summer, they had all completely germinated, and the radicals had projected some four or five lines.

As to the production of the gas, we shall observe that that which was disengaged, traversed the water, and passed through the tube into the receiver, was only the sign of the function; and nothing more than the overplus of that which was dissolved in the water at the moment it was formed; it must also have been in very small quantity. The proportion of air which had traversed the water without being dissolved by it, amounted to between 20 and 40 millilitres; but that which was dissolved in the water, and which was disengaged by boiling, was very considerable, and might well, as it did, surprise us.

The whole interest of the experiment here depends upon the quantity of the air naturally contained in the water, compared with that which had been produced by the seed. Accordingly, we made many experiments to ascertain the proportion of air contained in the water of the well which we used; and we found that the water in our bottles before the experiments, as the mean of our observations, contained 7.5 centilitres of air, and after the experiment 55.5 centilitres, in an experiment of five days' continuance. Hence, after subtracting the air naturally contained in the water, we find 47.7 centilitres of gas, produced solely by the action of the water and the beans. The result of another experiment, which lasted for six days, after making the same subtraction, was 50.5 centilitres of gas, produced above the quantity of air naturally dissolved in the water of the bottle. There was, therefore, disengaged by the sole action of the seeds and the water, after subtracting the air which the latter contained, more than half a pint of gas; a very remarkable effect, and which, when seen on so great a scale, leaves not the slightest doubt as to the action of water in the respiration of beans, abstraction being made for the air contained in the liquid.

Our next object was to ascertain what information analysis would give us respecting the nature of the gas supplied by the seeds. And first, there was an enormous proportion of carbonic acid. Of the 55 centilitres produced by the experiment of five days' continuance in summer, 48 were carbonic acid. 2dly, An infinitely small quantity, 2.5 millilitres was oxygen, and about 3.5 centilitres, which appeared to be nitrogen. In short, there was, 1st, an enormous quantity of carbonic acid; 2dly, scarcely any oxygen; and, 3dly, a quantity of gas, which, in the mean while, we shall regard as formed entirely of nitrogen, and which amounted to somewhat less than the quantity of air contained in the water.—On another occasion, we shall consider whether any other gas was present.

Whence, then, proceeded this enormous quantity of carbonic acid, in the production of which the air contained in the water must be counted for nothing? It is clear, that since the oxygen does not proceed from the air dissolved in the water, it must be derived from one of the elements of the water itself. The water, therefore, is decomposed; the oxygen, one of its elements, unites itself to the carbon of the seed, and forms the carbonic acid which disengages itself in whole or in part; a question into which we shall enter upon another opportunity.

It now remains to inquire what becomes of the hydrogen, the other element of the water? We suppose, for the moment, that there is no trace of it, as we have stated provisionally above; and since it is not disengaged, it must evidently be absorbed by the seed.

Hence, the results which follow from the experiments which we have detailed, from seeds placed in the conditions stated, are, 1st, that the water is decomposed; 2d, that the oxygen of the decomposed portion, unites with the carbon of the seed, and forms carbonic acid gas; 3d, that this carbonic acid disengages itself from the seed, in whole or in part; and 4thly, the other portion of the decomposed water, the hydrogen, is absorbed by the seed, in whole or in part. These are the four fundamental propositions regarding the respiration of seeds, to which we shall confine ourselves on the present occasion.

It is not a matter of very great moment to ascertain whether all the carbonic acid is completely disengaged. Nor is it of more consequence that we should know at present if all the hydrogen, rendered free by the decomposition of the water, is completely absorbed by the seed; subjects which, however, we shall discuss on another occasion. The great fundamental fact brought out by these researches is the decomposition of water, a fact quite foreign to the popular theory of the present day.

It also results from the facts which we have propounded, that respiration is not, as it has hitherto been considered, solely a function of excretion; but it at the same time exhibits, according as we have demonstrated, a fundamental fact concerning the nutrition and the development of the embryo by the absorption of hydrogen.

In addition to the respiration of seeds, a great variety of which we have examined, we have also investigated that of bulbs, twigs, leaves, and flowers, the results of which we hope to have the honor of presenting to the Academy. We may, however, remark, that the facts detailed in this memoir, regarding the respiration of the seed, form the basis of the respiration of other parts of the plant, as will be more clearly exhibited in the sequel, as well as the part which the air plays in this important function.—*Edinburgh New Philosophical Journal.*

Visit to the Farm of Elias Phinney, Esq. of Lexington, Mass.

[*From the New-England Farmer.*]

We have in the farm of this gentleman substantial proof of the efficacy of "book farming." He assured us that his interest in agriculture was first awakened by reading the N. E. Farmer. Having received a classical education, he has to be sure, the advantage of our farmers in general, for whom so little has been done by education—we were prepared, therefore, in viewing his premises, to witness something a little extra, from what may be seen on well cultivated farms in general: but we found that our expectations had not been raised sufficiently high: we were in fact delighted and astonished to be made acquainted with the wonderful improvements which have been effected on this place since he began to cultivate it, fourteen or fifteen years since.—It was then a poor worn out farm, covered with rocks, whortleberry bushes, and scrub oaks; while the lowlands were inaccessible quagmires and alder swamps of the most unpromising description—the whole farm, consisting of 160 acres, not affording more than 8 or 10 tons of hay, and all other crops in the same proportion—the fences out of repair—the fruit of an inferior quality, fit only for cider—and every thing upon the place at sixes and sevens, as the saying is. It does not seem hardly possible that so much could have been achieved in so short a time. It shows what can be done by untiring diligence directed by science. It is a a complete triumph of "book-farming" over the old course of husbandry, handed down from father to son. Mr. Phinney has had the boldness to strike out of the old path, and in some instances pursue a course of his own invention. His improvements may be divided as follows:

1st. In planting upon the green sward without disturbing the sod.

2.d In clearing and draining his waste swamps and quagmires, and converting them into the most productive grass and cornfields.

3d. In clearing his uplands of rocks and laying them into walls of the most durable and massive description subduing the bushes in the unproductive pastures, and bringing them into fertile fields.

4th. In his orchard of apple-trees, which for beauty, thrift and produce, can hardly be excelled.

5th. In his choice collection of fruits of every desirable variety.

6th. In his improved breed of swine.

7th. His barns and accommodations for cattle, swine, poultry, &c.

To which may be added, many other improvements of minor importance, but which add to the interest, beauty, and profit of the place.

The idea of planting upon the green sward without disturbing the sod, has been ridiculed by a writer in the N. E. Farmer, vol. 17, page 317, as being impracticable, especially in the potato crop. We saw an example of this operation, and one too of a most perfect kind, which we should suppose sufficient to convince the most sceptical. It was in a lot of three acres of potatoes. On the 20th of June, there was a heavy crop of grass upon the ground, in addition to which twenty loads of compost to the acre was spread on, and at that time turned over; after ploughing, it was rolled with a heavy roller, (an implement, by the way, which should be in the possession of every one who calls himself a farmer.) The potatoes were planted in drills—had been hoed but once—yet hardly a weed was to be seen, nor a spear of grass daring to show itself, and sufficient earth about the plants, with every prospect of an abundant harvest.—In the spring this ground will be in fine order to lay down again to grass, and that, too, without disturbing the sod; or, if advisable, planted with corn or any other crop.

Allowing the vegetable matter turned in equal to 20 loads of compost per acre, we have with that spread what is equivalent to 40 loads per acre. No wonder, then, that by following this process continually, he should be able to cut from 2½ to 3½ tons of hay per acre, which he actually does from his grass lands. He has another idea which we think important for a good crop of grass; that is, to sow an abundance of seed. His rule is 20lbs. of clover seed per acre, together with a liberal allowance of herd's grass and red top to boot. This would astonish most of our farmers, who can afford only from 4 to 10lbs. per acre.

We saw a field of six acres of corn, from which a crop of 80 bushels to the acre is estimated, and provided we have warm weather sufficient to ripen any corn, we should judge the estimate not too high; the cold weather a few days past is, however, against the corn crop. The variety of corn planted is called the Phinney—a fine long eared, twelve rowed variety, and earlier than the Dutton, to which it has some resemblance.

In another lot on his peat meadow, we saw a smaller field, on which the corn was more luxuriant and promising than on the one just named, and if that produces 80 bushels, we should not be surprised if this produced 100 bushels to the acre. Think of this, you that own unreclaimed peat meadows, and are longing for the fertile prairies of the west; before you sacrifice your farms and bid adieu to the institutions and hills of New-England, make an effort and bring them into subjection: it will prove an antidote to the western fever, or we are much mistaken.

We noticed a fine field of wheat of 8 acres, which the laborers were gathering into the granary. It appeared well filled out: the produce estimated at 20 bushels per acre: it was of the variety called the Black Sea, which we find succeeds best in the vicinity of Boston, and most generally cultivated. We were informed that about 30 acres were under the plough the present season. Besides Indian corn, potatoes and English grain, Mr. Phinney cultivates the root crop extensively. His ruta bagas, mangel wurtzels, sugar beets and carrots looked very promising, and will afford an abundance of food for his numerous family of swine and other stock.

In draining his low lands, Mr. Phinney first cuts off all springs from the surrounding hills, by a deep cut at the margin or outer edge of the piece, which is converted into a blind ditch: from this most important cut, the drains are made to the centre ditch. Where there is an abundance of stones, as in this case, all the drains may be filled and covered over, so that the operations of the plough, &c. may not be impeded. We were shown one piece over which it was dangerous for his cattle to pass, and in which they sometimes got mired, before he commenced the draining process; here his first essay on draining had been made, in which, through inexperience, he cut only the centre and cross drains, but with all he did, it would produce nothing but skunk's cabbage, hellebore, brakes, &c. and it seemed that all his labor had been lost, until he learned the importance of the ditch around the margin, which produced the desired effect, and now it ranks among his most productive grass lots, and a loaded team may be driven without difficulty over it.

We were pleased with his system of digging peat, of which he has ample an supply. Where peat is generally dug, the grounds are left in the roughest state, and present an unpleasant and unsightly appearance, and remain an unproductive waste: but it is his rule to have the top spit, a depth of ten inches or a foot, (the portion unfit for the fire,) thrown over and levelled as the work of digging proceeds: in this way it soon becomes covered with grass, which answers very well for stock hay.

One peculiar feature of this farm is the massive stone walls by which it is enclosed and divided. It would seem a Herculean task to build the wall that has been put up under the care of the intelligent proprietor. In the measurement of the length of wall upon the farm, we may safely say there are miles of it—we know not how much there may be—on this subject we are not informed—one piece of considerable length, is 10 or 11 feet thick, 7 feet high, and covered with grapes, which have been set out on the south side of it; a fine native variety found on the place. The vines were loaded with fruit, and bring by the quantity from 8 to 10 cents per pound; we should judge there might be a ton of them. All the other walls are double, from 5 to 10 feet thick and 5 to 6 feet high, and must have consumed an enormous quantity of stone. We noticed grapes upon many other portions of wall.

The orchard on this farm is equal if not superior to any we have seen. It contains from 400 to 500 trees, principally Baldwins, Russets, and Rhode-Island Greenings. It produced a very abundant crop last year, but this year there is scarcely an apple upon it. It was planted somewhere about 14 or 15 years since. The soil is generally a light rich loam, upon a gravelly, and in some places, a rocky foundation. The trees were taken from the nursery in autumn, and placed in trenches until the following spring. They were planted near the surface, and in many instances, upon the surface, without digging any holes, and the dirt placed upon the roots. The orchard is situated on a side-hill, having a south and southeast exposure. Many of the trees were severely injured by the hard winters of 1835 and '36, which caused the destruction of some of them. Their places have since been supplied with young trees. The mice injured some of the trees a number of years since, by gnawing the bark, so that in some cases the trees were completely girdled, and to all appearance lost. An ingenious method was devised to save them. Having prepared some large scions, five or six of them were inserted in each tree, below the wounds in the bark, and then connected with bark above by the common operation of side grafting; in this way the sap was conducted from the roots to the top, and the trees saved. We saw some of the trees thus operated upon: the scions had increased to the diameter of three or four inches, and had nearly come in contact with each other; we should doubt, however, whether the trees would be long-lived, as the old wood must be unsound, and an early decay must be the consequence. The trees appeared now as vigorous as any of their neighbors. The orchard has never been laid down to grass, but kept in constant cultivation. The trees are finely shaped, having been pruned with a skilful hand, and just high enough from the ground to work under without inconvenience: the trees are about two rods apart: in some places they nearly cover the ground. We do not remember how many barrels were gathered for the market last year, but the quantity was great. Besides this orchard, there is another that has been set out only two or three years, of 200 or 300 trees, all of which are sweet apples, designed expressly for the swine. All the refuse apples are fed to the hogs, and considered much more valuable for that use than for cider.

The farm is abundantly stocked with pears, plums, peaches, grapes, &c. There are more than 2,000 fruit trees of various sorts upon the place, and all have been reared and pruned by the hand of the proprietor himself.

One of the most pleasant sights is a trellis 30 rods in in length, covered with the Isabella grape, from which was gathered last year two tons of grapes, which found a ready sale in Boston market at 10 to 12 cents per pound. The crop was said not to be so heavy this year, but to us it appeared very great. There is also a small house where the more delicious foreign grapes are grown.

The plums had suffered severely from the curculio, and most of the trees had lost their fruit. There is a disease upon the currant bush, which we have noticed in many other places as well as on this. The bush loses its leaves prematurely, and the fruit becomes withered and worthless. We have in vain sought for the cause. Can any of our readers inform us, and prescribe a remedy? The vegetable garden is large and well stocked with every variety: what is not consumed in the family is marketed or fed to the swine.

Mr. Phinney has taken great pains to improve his breed of swine, and probable there are none superior in the state. As we have a promise from him of a description of his pigs and piggery for the N. E. Farmer, we shall not enlarge upon this subject. He prefers a cross of the Berkshire and Mackey to any other, and most of his pigs for slaughter are of this description. He has the full blooded Berkshire, Mackey and other breeds, and mixes to suit himself. We noticed a sow lately imported from England, called the Essex half black: the hinder part of the animal is jet black, and the forward half white. There are some good points about her, and she may prove a valuable acquisition to his stock: not having recovered from her sea voyage, she does not appear now as she will after a few weeks of good keeping. There is an old sow here, quite an object of curiosity, (we do not recollect the breed,) that weighs 900 lbs. a monstrous overgrown animal; she had been turned out of her pen to enjoy her liberty a little, which she did not, however, seem to appreciate much, as all the room she wanted appeared to be enough to turn round and lie down upon. She looks as though she might be the parent of a most numerous offspring, but we understood she was without issue, having apparently no inclination to form an intimacy with the other sex. The number of swine is about 140, the care of which employs one man constantly.

The barns and other buildings for the accommodation of stock, are convenient and comfortable, with sufficient room for the hay and grain produced on the farm.—About 100 tons of hay are cut annually, part of which is sold. For every ton of hay sold, one cord of manure is purchased. To improve the land and keep it in high tilth, it is necessary of course to manufacture a large amount of manure. This is first done by the hogs. The man who has the care of them is constantly employed at odd hours in furnishing them materials, such as meadow mud, peat, weeds, &c.: second, by sheep: in autumn 150 or 200 wethers are purchased from the droves, and fed through the winter: by March they are in good flesh and bring a high price, and pay well for their keeping; their yards being furnished with plenty of mud and litter, when mixed by their excrements makes a rich compost: third, by the other stock and the manure purchased, which is carefully mixed with twice the quantity of meadow manure. One cord of this composition is considered about equal to one cord of stable manure alone.

In making our observations upon this place, we feel as if it was not in our power to do it justice, as we spent but a few hours upon it. Every part of it shows, that by science, industry and skill, it has been rendered worthy of being ranked among the first of well cultivated farms in New-England, and its proprietor worthy of all praise for the laudable example he has set for the imitation of his agricultural brethren. J. B.

On Bones as a Manure for Turnips.

[*From the Farmers' Magazine.*]

Sir—Seeing in your excellent periodical, *The Farmers' Magazine*, several opinions respecting the efficacy of bones as a manure for turnip land, some stating its beneficial effects to have been astonishing; while others assert, and with equal truth, that from trials made by them, no benefit whatever has resulted from their use, it would seem very difficult to account for this difference of opinion, more especially when trials have been made by intelligent and practical farmers for several years. Those who found it beneficial, continued its use; while others, who, upon trial, experienced the reverse, gave it up as not answering their purpose, without further trials or further investigation as to the cause, why it is not beneficial to the crops on all soils. Now, if its salutary effects are as stated by its advocates, it must surely be worth inquiry, and ought to be investigated by scientific men, who would render a lasting benefit to the farming interest, by showing on what soils it could be used with advantage, and also those soils where its application would be nugatory. This would save many from a heedless expense and a consequent disappointment in the crop.

It appears, by an article in your number for June last, that an excellent lecture had been delivered, at the Woodbridge Literary Institution, by a Mr. Webster; in the course of which he alluded to the merits of bones as a manure, and briefly described a method whereby their adulteration might be detected; and this adultera tion may be done in various ways, and for very different purposes, and appears to me to be a main cause, though not entirely, why on some soils they succeed well, why on others partially, and why again on others a total failure.

As it is necessary, for the investigation of this subject, that the component parts of bones should be understood by every one interested in their use as a manure, I beg to submit, for the benefit of those of your readers who may have not seen a better, an extract from an analysis by that eminent chemist, Mr. Hatchett. He says—

"The component parts of bones are chiefly four, viz. the earthy salts, fat, gelatine, and cartilage.

"The earthy salts are three in number—

"1. Phosphate of lime.

"2. Carbonate of lime.

"3. Sulphate of lime.

"The proportion of fat seems to vary from one-sixth to one-fourth of the weight of the bone."

Annexed is also a table, calculated from experiments made from bones, both of the human species and also from various animals (by the same chemist) :—

100 parts contain of the	Gelatine.	Phosphate of Lime.	Carbonate of Lime.	Loss.	Total.
Human,.	23	63	2	2	100
Horse,..	9	67.5	1.25	22.25	100
Ox,....	3	93	2	2	100
Sheep,..	16	70	0.5	13.5	100
Swine,..	17	52	1	30	100
Calf,...	25	54	...	21	100
Elk,....	1.5	90	1	7.5	100

This it appears, that the bones of the Human species and of the calf afford the most gelatine, and those of the ox and horse the least except the elk.

The gelatine, the most beneficial portion to the land, is also an important ingredient in making portable soups, and also in the manufacture of glue; and there can be little doubt that, in most cases, the gelatine is, with the fat, extracted from the bones, by boiling or otherwise, before they are sent to the mills to be crushed the manure. The weight of the gelatine is about one sixteenth of the bone.

Thus the bones, after the gelatine and fat have been extracted, are divested of their most enriching properties, and little remains but lime, which on some soils will do good, but not to the degree it ought, and on others none at all; and, as Mr. Webster observes in his excellent lecture, that "the farmers can purchase that in great abundance, and at a much cheaper rate." He is also of opinion, "that for every cwt. of bones carted upon the land in an unadulterated state, you have one one-fourth hundred of flesh; and is not animal matter (he continues) the food of plants?" He also quotes, in corroboration of his argument, some experiments made by the late T. A. Knight, Esq. of Downton Castle, the eminent horticulturist, relative to watering plants with broth made from bones.

If we were to notice the great difference in the essential parts, by a reference to the annexed table, it might lead into an inquiry why the vast quantity of bones, imported from the continent a few years ago, were found so excellent in quality, and so stimulating in their effects.

Vast quantities of bones are collected in carts, from the butchers' shops in the metropolis, in their raw state, all the meat having been previously cut from them; these bones are taken to persons who, by roasting and boiling, extract from them every particle of gelatine and fat they contain; nothing then remains to benefit the land but the cartilage contained in the earthy salts. By the above process, a great quantity of nutritious food is extracted for the service of man, and other purposes connected with his comfort and advantage, and consequently to the general advantage of the public: and although there is nothing to regret that their essential parts are extracted for such valuable purposes, still we must not be surprised that bone manure is found, in many cases, deficient in its fertilizing effects upon the land, and often disappoints the sanguine expectation of the industrious cultivator. I remain, sir, yours, &c.

THOMAS JOY.

On Influenza in Sheep.

[*From the Veterinarian.*]

TO THE VETERINARY MEDICAL ASSOCIATION.

Gentlemen,—You having been pleased to elect me one of your corresponding members, renders it almost imperative that I should attempt some return for that distinguished honor. As an humble member of the veterinary profession, I am willing to contribute the little that I am able towards the advancement of our common science; and therefore I venture to lay before you a few observations on the disease to which sheep are liable in this locality, and which is often attended with considerable loss to the grazier.

The treatment of cattle and of sheep is a division of our art by many contemned. Such, perhaps, have not resided in districts that have called forth the energies of their minds; nor have they seen the ravages which disease often produces: had they, I feel assured, that the comments which from time to time are made, would be thought unworthy of scientific men, and especially of those to whom the health of our domesticated animals should have been, and even now is, in a great measure entrusted. There are many cogent reasons why instructions should be commenced in good earnest at our *alma mater* on this division of our art; but, as the full consideration of this would lead me into a field of argument I am not, at present, desirious of entering on, I will leave it, and pass to the more immediate object of my paper; craving, however, permission to say, that I am glad to see that reform has been commenced. I feel assured that steps will be taken to ensure its progress, and to perfect the system. Thus, I trust, speedily and for ever will be wiped away a stigma which has been long attached to the profession of a veterinary surgeon in country practice. These are not days in which we can retrograde; but we must continue the onward march which has been so nobly begun, and to which the association lends its powerful aid.

The malady to which I refer is INFLUENZA IN SHEEP; at least I call it by this name, because it bears so great a resemblance to that disease in the horse.

The situations in which I have found it most prevalent, are the marshes near the sea. The land there is very good, but much exposed; there being no hedges nor inclosures for many square miles. Cases are most abundant during the months of March and April, and especially when easterly winds prevail. It generally attacks young sheep, such as are called *lambs hogs*, and almost always those that are in the best condition, and of the largest size.

To prevent repetition, I will give you an account of a flock of 180 that I attended, in April 1838, for these presented the general features of the many, and may therefore be taken as a type of all the other flocks which were affected. They belonged to a wealthy grazier, Mr. G. Curbets, residing at Croft, near this place.

It was on the 19th of April that I was first desired to attend them. On my arrival, I found seven or eight dead. They were observed to be ill on the day previous to my seeing them. There were eight more that could not stand; and when lifted up, they had entirely lost all power of motion. On examining the remainder of the flock, I found some scarcely affected at all, while others were gradually going on in the same way as those that had died.

The first symptoms exhibited were, dulness of countenance, and a disinclination to join the rest of their companions, or to look out for food. They soon became more dull; a thin mucous discharge made its appearance from the nose and eyes, the tissues being highly injected; the ears drooped; a grating of the teeth was heard; and a staggering gait evinced in walking. As the disease advanced, all the above named symptoms became more manifest. The animals were able to walk at a slow pace, but if urged into a quicker one they would fall down on their knees, and then on their sides, throw their heads back, and grate their teeth as if in pain. After lying a few minutes they would get up again, although with difficulty; and their manner of walking in this stage of the disease very much resembled a horse laboring under inflamed laminæ. When the disease had been allowed to run on to this height the sheep often became affected with spontaneous diarrhœa, the fæces appearing to come away involuntarily. Those that did not purge, usually voided much mucus encoating the dung.

After this they quickly became worse: they would lie perfectly still, as far as the limbs were concerned, but they continued to grate their teeth, and a rattling noise was heard in the windpipe, accompanied by a frothy discharge from the mouth and nose, and an occasional cough. To this death succeeded in a few hours.

The post-mortem appearances were very unsatisfactory, as no particular part appeared to be more affected than another by the disease. On examining the windpipe the lining membrane was found to be slightly inflamed; the bronchi contained a frothy kind of fluid; the substance of the lungs was a little engorged, but this was not invariably the case; the lining membrane of the chest was also sometimes a little tinged, and most altered in character about the sternum and cartilages of the ribs; the heart appeared quite healthy, as did the abdominal viscera, except the peritoneal and mucous coats of the small intestines, which were now and then tinted with an inflammatory blush.

Generally speaking, if any part more than another could be said to have taken on active inflammation, it was the kidneys, these organs being not uncommonly found discoloured in their emulgent portion, but nothing like approaching mortification. The tubular part was also a little darker than natural, and easily broken down by the fingers; but the pelvis had not undergone any structural disorganization. The urine appeared to have been naturally secreted, and the coats of the bladder were healthy; but sometimes this viscus was distended more than is usually found. The brain presented no abnormal appearance. Such were the lesions observable on the examination of several of them.

The treatment I pursued with those which could not stand, was first to place them under a shed, with plenty of dry straw to lie upon. To those affected with diarrhœa, astringents were administered, such as catechu, chalk, &c. combining them with an aromatic tonic and the spiritus etheris nitrici: while to others that were constipated in the bowels I gave a gentle laxative, following it up with a vegetable tonic. This course of procedure appeared to be attended with benefit; for, out of the eight that could not stand, four recovered, and were able to provide for themselves in two or three days. After the exhibition of the medicine to the diseased, the remainder of the flock was removed into as sheltered a situation as could be found; or sheds were erected for them, with plenty of dry straw to lie upon. A liberal diet of oats and hay was allowed, while their general comfort was as much attended to as possible. To many that gave indications of the approach of an attack of the malady, a laxative and a tonic combined was given.

On April 21st, the sheep were not only looking better, but had very materially improved. The above-mentioned treatment was continued, with occasional variations, according to the circumstances of each case; and in five or six days they were all out of danger. I am happy to be enabled to say, that after this there were not more than two or three sheep out of the flock in which the prostration of strength became so great as to render them unable to stand; and I would add, that I never knew one case to recover without the aid of medicine, after the disease had existed so long as to produce this loss of power. I am, &c.

Vegetation—(*Concluded.*)

The sap ascends to the leaves, where it undergoes certain alterations, and is converted into the peculiar juices, which like the blood in animals, are afterwards employed in forming the various substances found in plants. Great part of the sap when arrived at the leaves, is thrown off by evaporation, by means of particular organs. What remains must be very different in its proportions from the sap. It is performed chiefly by the upper surfaces of leaves.

Leaves have also the property of absorbing carbonic acid gas from the atmosphere, and have been supposed to exhale much pure air. Hence they have been universally deemed highly useful, when planted near a house, but though useful as a source of shade, yet the following observations will shew that their benefit does not depend upon the supposed addition of pure air, derived from them, to the atmosphere.

The air of the atmosphere, according to the most celebrated chemists, is composed of twenty-two parts of oxigenous gas or air, and seventy-eight parts of azotic gas. There is a constant consumption of the oxigenous portion of this air, by the burning of combustible bodies; by the respiration of animals; by the fermentation and putrefaction of vegetable and animal substances; and by the calcination of metals. The oxigenous gas, decomposed by respiration and combustion only, in the city of London, is supposed to amount to the enormous quantity of five millions cubic feet an hour. (Nicholson's *Philosophical Journal*, vol. v. p. 184.)

The atmospheric air of Great Britain, France, of parts of Africa, and of America, has been examined by philosophers, and has been found to be exactly of the same degree of purity.

The oxigenous gas contained in it, is in the same proportion, at all times and in all places, in rainy or in dry weather, in depth of winter, and in the middle of summer, on the land and on the ocean, in the crowded city and remote village.

In consequence of a most valuable discovery, made by the illustrious Dr. Priestley, that growing vegetables under certain circumstances, exposed to the light of the sun, yield oxigenous gas: an opinion has been adopted, that they are the sources of the oxigenous part of common air.

This sentiment has been adopted by the chemists of all nations, but has been controverted by Dr. James Woodhouse, formerly professor of chemistry in the University of Pennsylvania. (Nicholson's *Philosophical Journal*, June, 1802.)

The Doctor reasons in the following manner.

1st. He says, whenever oxigenous gas has been obtained from vegetables, carbonic acid, (or fixed air,) has been present. Upon reviewing the experiments of Dr. Priestley, he finds that this circumstance has actually taken place. The Dr. exposed plants to the influence of light, in atmospheric air, in which spirit of wine, and wax and tallow candles, had burned out; to air which had been vitiated by the death or putrefaction of mice and fishes; and to air which had been frequently taken into his lungs; and found that the purity of the air, was in every instance restored. Priestley on Air, vol. iii. p. 247 to 347.

In all these cases carbonic acid, (which is composed of carbon and oxygen) was formed; the vegetable devoured its coal for food, by which means its oxygen escaped, in the form of pure air.

2dly. The seeds of Zea mayz (Indian corn,) of *apium petroselinum* or parsley, of *lactuca sativa* or lettuce, of *cucurbita citrullus* or the water-melon, of *phaseolus sativus* or beans, and of *raphanus sativus* or radishes, were planted in earth, and made to vegetate in atmospheric air, confined over water in vessels of white glass, and exposed to the action of solar light. This air, when examined at various times, was found to be reduced in purity, and when its oxigenous portion was completely absorbed the plants died. Its oxygen united to the coal of the cotyledons of the seeds, or to that of some animal or vegetable matter contained in the earth, in which they were planted, or to that of some decayed portion of the living leaves, and formed carbonic acid, quicker than the living plant could decompose it. To these experiments, we may add that the celebrated and accurate Scheele observed that beans growing in atmospheric air, always rendered it impure.

3dly. Young plants of *datura stramonium* or Jamestown weed, of *phytolacca decandra* or the poke, of Zea mayz or Indian corn, &c. growing in earth, were exposed to solar light in from forty to eighty ounce measures of atmospheric air, which was examined at various times, from one hour to thirty days after the plants had been placed in it. Carbonic acid gas was generally formed, and whenever this circumstance happened, the purity of the air was diminished.

When a plant in perfect health, growing in a soil which contains little vegetable or animal matter, is confined in atmospheric air, it will live a long time without producing any change in it. Many of the vegetables which were the subjects of these experiments, did not affect the air in five days; some diminished its purity in three hours, and others altered it in a most slow and gradual manner, causing little change in it, in 20 days.

4thly. Many of the same kind of vegetables were also confined in forty ounce measures of oxigenous gas, which had been well washed in lime water, and the purity of this air was very generally lessened, carbonic acid being formed.

5thly. A small handful of the healthy leaves of a variety of plants, containing no decayed parts, were exposed during four, six, and eight hours to the influence of the light of the sun, in atmospheric air confined by water, and its purity was found to be neither increased nor diminished.

6thly. The leaves of various vegetables gathered promiscuously, exposed in the same manner, generally diminished the purity of atmospheric air, several degrees.

7thly. A handful of the leaves of several hundred different plants, among which may be mentioned, those of the apple, pear, peach, poplar, fringe, and persimon trees, were separately exposed during several hours in glass vessels to solar light, in forty ounce measures of pump water, and from five to nineteen drachm measures of oxygen air were produced in each vessel. Upon analyzing the water, it was found to contain carbonic acid, with which it had been impregnated from a necessary, which stood within a yard of the pump.

8thly. The leaves of 13 different plants were separately exposed in the usual manner, in forty ounce measures of the water of the river Schuylkill, and about ten drachm measures of air were procured, the principal part of which was azotic gas, which was disengaged from the water. No carbonic acid could be detected in the water of this river.

There are three wooden bridges erected over the Schuylkill, which rest upon large wooden logs, upon which great quantities of a species of conferva grow, and which is covered by the water. Upon viewing this vegetable when the sun shone upon it, for several hours, at different times, for several years, no air could be seen to form upon it, or to rise through the water.

9thly. The leaves of the same vegetables were exposed to light, in the same manner, in the same river water, impregnated with four quarts of the water, saturated with carbonic acid, from the carbonate of lime and the sulphuric acid: and 77 drachm measures of oxigenous air of a very high degree of purity, were obtained.

10thly. No oxigenous air could be procured by exposing vegetable leaves in boiled, distilled, rain, or lime water; a proof that they do not decompose water.

11thly. Atmospheric air was impregnated with carbonic acid gas, and a handful of the leaves of nine different vegetables were separately exposed in it, to light, seven hours. The fixed air disappeared, and the atmospheric air was greatly increased in purity.

12thly. The limbs of trees covered with healthy leaves, and some vigorous evergreens growing in their natural soil, were confined from one day to a month in atmospheric air, over water, and exposed to light, and its purity was never found to be increased, but was generally considerably diminished.

These experiments incontestibly prove, that whenever oxygen gas has been obtained from vegetables, by exposing them to the influence of solar light, carbonic acid has been present, and that it is from the decomposition of this gas, that the pure air is obtained.

As it is acknowledged that the leaves of plants separate the oxygen from carbonic acid, it may be said, that the oxygenous portion of atmospheric air is supplied by the decomposition of gas, as it is always found in the atmosphere. The quantity of carbonic acid, accidentally diffused in atmospheric air, (for it is not of its component parts) is reckoned to be about one part in an hundred. It must however vary in different places. We would expect to find the most of it in cities, where it is formed by combustion, respiration, fermentation and putrefaction. If one measure of the air of any great city, be passed up over lime-water, in an eudiometer, no carbonate of lime will be formed; so that the quantity of carbonate acid in this air, must be extremely small. As this gas is also seized upon by alkalies, earths and metals, and absorbed by water, the proportion of it in the atmosphere, may be less than one part in ten thousand.

When we consider likewise that the oxygen is never separated from the carbonic acid by leaves, but when they are exposed in contact with it to the light of the sun, and that every perforation made in a living leaf, however minute, by an insect, causes the part to decay, and absorb oxygen by day and by night; and that in the autumn, in some countries, all leaves fall on the ground, ferment and putrify, and thus diminish the purity of common air, and that the petals and fruit of vegetables have the same effect, we must pronounce, that the oxygenous portion of atmospheric air cannot be supplied by vegetation.—*Domestic Encyclopedia.*

Bees.

[*From the New-England Farmer.*]

Mr. Colman.—We wonder every body does not keep bees, such active beings as they are and so liberal in dispensing "the sweets of life." Yet we are glad they do not, for if they did, even though they had a "small beginning," they would at length become so numerous that sad consequences might result. This we have found to be the case to our cost, for in the spring of 1833, we established a colony, which, as there were none about us, did very well, and our success excited others to embark in the same enterprise, so that in two years they were "as thick as bees" through the neighborhood and town. The consequence was, all the bee pasture in the community was overstocked, and the long, severe winter which followed put an end to all our anticipated sweets, inasmuch as that there was scarcely a hive remaining in the circle of our acquaintance, whose inhabitants could be numbered among the living. We might have saved ours in a way which we shall speak of soon, but they had a usual supply of honey and we did not expect an unusual winter.

Last spring, we obtained a hive and began again.—Maugre the cold wet May and June, we have obtained three swarms from it, the hives of two of which are very heavy and the third in quite a winterable condition. Our first swarm came off about the middle of May, and lit on a current bush, consequently we had no trouble in hiving it, but the second which came off only a few days later, displayed an obstinacy worthy of the human species, for they lit on the body of a beautiful maple on one side of our yard, just at the place where the lower branches put out. We tried almost as many devices to get them off as the "old man" did to drive "the rude boy" from his apple tree and with no better success; we jarred the tree, but we could not jar them off; we tried to brush them down, but to this they objected; we confined a hive to the tree, and wound a cloth around it and them, hoping to lure them to a domicil in this way, but they had no more ambition to climb, than propensity to descend. We however secured them where they were in this way, for that day and the coming night, which brought the elements to our aid in the form of a "hoarse north easter" cold with wind and tolerably charged with rain, which two qualities united so benumbed the physical faculties of our truant friends, that we could dispose of them as we pleased; we accordingly with all care took them down and placed those which possessed animation in the hive, while the remainder we protected from the storm, and on the first sunny day laid them out *to dry*. Most of them revived and joined their family, but their tranquility was of short duration, for in consequence of their exposure, a dysentery attacked some of the community, and those in health, instead of remaining to protect the weak and heal the sick saw fit to decamp, and after enjoying a healthful sailing excursion in the air they went to the hive in which the first swarm had been put. Their stay there was not very tedious, for in a week or ten days and instead of aspiring to the trunk of a choice shade, at ten feet from the ground, their "meek and lowly spirits," led them to cluster on a raspberry bush but a few inches from the surface, from which they were taken and put in a condition satisfactory to themselves, as their quietude and thrift fully attest.

Our last swarm came off in June, and notwithstanding the old adage that "a swarm in June is not worth a spoon," we should refuse an offer of two spoons for this, and more unless they were very nice and very heavy. True, the quantity of honey which they have gathered is not very great, but with our way of managing such hives we think amply sufficient for their supply. We propose burying them, through the winter, a practice which we have adopted in two successive years, and had we continued it the third, our old colony instead of coming to an untimely end, would probably have been in existence now through its descendants.

My method of burying bees is as follows. The operation is performed the last of November. The pit in which they are to be placed is dug considerably larger than the hives, in every respect. On the bottom of the pit two sticks, say of scantling four inches square, are placed that a cavity may be left into which the water if there is any may settle and run off without injury to the bees. On these blocks I lay my floor board, which should be *sound* and full an inch thick, if more no matter.—The top of the hive should be covered with a two inch plank, or if more convenient, a piece of wide thick slab with the rounding side up, so that if the frost comes out, and heavy rains fall, it may serve as a roof to carry the water from over the hive and turn it into the pit below. Straw is then placed as compactly as may be around the hive and the earth thrown on so as to form a cone above it, which again operates as a roof to turn the water as it falls. With regard to the depth of burying we can only say, that in our former experiments, we never sunk the top of the hive below the surface.—Whether it would be well to do so we cannot say. Some when burying their bees, drive down a stake near the hive as they say to admit the air, but we do not see why a stake drove down with the earth compactly placed around it, can form an air hole more than the earth itself. And if it could, we do not see the necessity of it, for the object of burying bees, is to put them as much as may be in a state of dormancy through the winter, by which their stock of provisions is lengthened out, to secure them from sudden and often fatal changes from heat and cold and from storm and sunshine.

In selecting a place for burying, it is important that a *dry* one should be chosen; and *we* prefer one that is cold to a warm one; and could we regulate the condition of the earth around them, we would freeze it the night after their burial, and *keep it frozen* until time for their exhumation in the spring.

We in both instances of our former burying, took them up some of the last days of March, and all the dead we found from the four hives thus kept would not half fill a person's hand, and on exposure to the sun and atmosphere the living were as bright and lively as though they had known no winter, and they gave swarms earlier and more frequently than did the hives that were not buried the ensuing summer.

We have thus far kept only the old fashioned square hives, but intend during the coming winter to have some manufactured after the Griffith and perhaps other plans. We shall do so, not that we have any particular objection to the square hive, but in order to profit by improvements in the article; and to do this we wish to give each variety a trial.

Our hives have uniformly been made of pine boards, and put together in the closest manner possible, after which we have spread a salve made of beeswax, tallow and rosin over the joints within and without. This wax gives the hive an odor very pleasant to the bee, in consequence of their wax being a part of its composition. It also closes the small apertures which are most always to be found in bee-hives against the invasion of the miller, one of the most formidable enemies to bee culture; and where the hives stand out, as they often do, it prevents the storm from beating through openings, which if no preventives be employed, are always increasing in size. Any sweet wood is undoubtedly good for hives, but economy and durability should be consulted in their manufacture as well as every thing else. Hence the cheapest material that can be used, with the approbation (we can do nothing without this) of those who are to inhabit them, should be. Basswood is cheap and sweet, and we know not why a basswood hive, kept sheltered, would not last for ages. To secure its durability it may be planed on the outside and painted, and we know not why the industrious bees would not enjoy a neat white house, and are not as worthy of such a one as many *biped drones* who inhabit them. We think the practice of placing boxes on the hives for obtaining honey a good one, especially when the swarm is thrifty. After the proper season of swarming time is passed, the box may be placed on the hive and prevent future swarms from coming out; and in this way the increase of bees may be saved in the old hive, where there will be honey enough for them, and new swarms come off *earlier* the next season, while as much honey may be obtained from the box as the late swarm would collect, without the sacrifice of their lives. The honey thus obtained is of the purest quality. The aperture in the top of the hive through which they pass to the box should be closed when the box is removed, and remain so until it is replaced the next summer.

Bee pasture. The man who turns his herds or his flocks upon their own resources for a subsistence, can expect but little profit from them, unless they become highway robbers, (and then the partaker is *worse* than the thief) and enter his neighbor's fields and spoil his crops. Though we have no idea that a community of bees can be restrained by fences, pokes or fetters, yet we do think that their rambling propensities may be checked. The facilities of their labor increase their enterprise, and the *endearments* of their *home* made still *more* dear by—we should have said cultivating flowers for their benefit, but this would sound *weak* to the ears of some *strong minds*, so to such we say *allowing* them to grow.

But the ladies admire flowers—so do *gentlemen*, therefore we have no hesitancy in recommending their culture, especially when so many objects of utility demand it, as in the present case. The mignionette is a beautiful little flower, and when once sown will keep itself in, if the ground is kept clean. It continues blossoming very late, its fragrance perfumes the atmosphere agreeably, to a great distance, and bees are as fond of it as we are of honey. The raspberry and bramble flowers are favorites with them, and we never heard a person say that they did not like their fruit, so *they* should be set plentifully in the garden and *cultivated*, that they may, *at home*, produce an abundance of flowers for the bees and fruit for man. The strawberry too, that we unitedly love so well, should always be found growing for our mutual benefit in our common gardens. The poppy, though somewhat calculated to lull the drowsy faculty of man to repose, possesses not the least lethargic quality to them, but in the reverse arouses their faculties. Catnip not in mints or juleps, but in blossom, they much admire. We too have tested the efficacy of its healing qualities through strong portions of its tea.

Yours truly, W. B.

Mount Osceola, Oct. 4, 1839.

[*From the (Va.) Farmers' Register.*]

Carelessness in Saving Silk-Worms' Eggs.

Stafford, Aug. 5th, 1839.

To the Editor of the Farmers' Register.—I am highly gratified that you have given the agricultural community a caution about silk-worm eggs. At least two-thirds of the failures in rearing silk-worms in this country may with propriety be attributed to bad eggs. Many persons raise silk-worms for the *sole* purpose of speculating on the eggs, and are probably not aware of the necessity of careful management to procure good eggs. Prevailing thoughtlessness on this subject, which I know exists extensively, if not checked, will throw serious obstacles in the way of this important culture, which I firmly believe is destined to repopulate the poor land districts in Virginia and Maryland. I will add a caution which may be of service to the inexperinced. If the cocoons intended for seed are thrown into a heap, and permitted to remain for several hours, when the weather is warm, the eggs produced will generally be worthless. I know this to be the fact from dear-bought experience.

"When silk-worms are to be raised, the eggs to be procured from the cocoons, must be thought of before anything else. Now-a-days when the cocoons are collected, it is the custom to keep them altogether upon the frames. Some persons not having time to reel all their silk, butterflies are seen to go out and lay eggs almost immediately. The accumulation of cocoons produce a kind of fermentation, and the heat causes the butterflies to hatch before the proper period. This premature development has never any good results, for the butterflies are sick; and from thence it comes that the silk-worms produced from their eggs, are affected by diseases from the moment of their hatching.

"The cocoons for reproduction ought to be separated, *and put in a well aired chamber*, and spread upon very clean mats, *a layer of the thickness of a single cocoon only.*" (*Chinese Treatise, published by P. Force, p.* 150.)

I have about 40,000 silk-worms of seven varieties.—They are remarkably healthly, and a large portion of them spinning in handsome style. Respectfully yours,

LAYTON Y. ATKINS.

P. S. There is no advantage to be derived from a forced and premature development of the silk-worm in any of its stages. The nearer the time of spinning to the natural period of its life, as stated by Dandolo, the better. The *precocious* and the *tardy* are always feeble, and eggs should never be saved from them. I have made nine rearings of the "two-crop" white, and of the cocoons formed between the 25th and 30th days it has required from 700 to 800 to weigh a pound, and so of the last which spin; but of cocoons formed from the 30th to the 35th day, 350 to 400 to make a pound. Depend upon it modern writers on silk-culture are promulgating a pernicious error on this point; and before the learned *silk-worm* doctors publish any more *infallible* prescriptions, I advise them to put on their spectacles and bring their remedies to bear on four or five cases.

If a *forced* and premature development is so important, what reason or sense would there be in the following passage from the Chinese Treatise:

"The moths which come out the first day are called *grass moths.* The last of all are called *mogno*, (that is to say, the last butterflies.) *Neither* of these ought *to be kept.*"

Mark the care of this people about procuring eggs. Cocoons are first selected, and when the butterflies come out, the *first* and the *last* are rejected. Let the people of the United States make numerous and careful experiments. We *beardless* boys of Virginia at least, do not mean to open wide our mouths and swallow nostrums as an unfledged bird does its food. L. Y. A.

To keep Sweet Potatoes.

[*From the Farmers' Register.*]

Some time last fall, as well as I now recollect, one of your Virginia correspondents asked for information upon the subject of keeping sweet potatoes through the winter; and perhaps the writer was desirous to obtain Virginia practice; but if our Georgia plan should not be altogether applicable to your region, (I know of no reason why it should not be,) your correspondent may derive some useful hints therefrom; and though I give our plan too late for any practical use the present season, it will, if at all, be of service the coming one. There are various modes adopted in Georgia for saving potatoes, but as the one I practise, in common with many others, has always been so successful, I shall describe that only. As soon as the frost slightly affects the potatoe vines in the fall, (about the middle of October here,) I begin to make preparations for digging; and by the time the vines become thoroughly killed, I am prepared for the harvest. I select an elevated piece of ground, and throwing up circular mounds or hills, twelve or fifteen inches above the common surface, the diameter of which should be about ten feet, to contain sixty bushels of potatoes. The situation and the elevation of the hills are objects of importance, to prevent the possibility of the potatoes getting wet. In order to make the potatoes lie on the hill the better, the edges should be some somewhat elevated by drawing the earth from the centre, giving it slightly the appearance of a bowl. Common pine heart boards are now placed on the earth, radiating from the centre to the circumference of the hill; and on these a layer one foot thick, of dry pine leaves. The hill being now ready to receive the potatoes, I select dry, mild weather, and commence digging in the morning, and stop time enough in the afternoon to haul up all dug during the day; for if left out at night, the frost, if any, would injure them. If possible, the hills should be filled and completed the same day, but if not, the potatoes should be well covered with straw to protect them at night, and uncovered next morning. When the pile becomes two or three feet high, place a pole horizontally across, of sufficient length to pass entirely through the sill. A better ventilator would be an oblong box four or five inches square, with several auger holes in it. The potatoes may now be put on till the pile is about five feet high, and left in a conical form. Next, procure dry pine leaves and lay them all over the potatoes, at least six inches thick. Pine heart boards like those used at the bottom of the potatoes, are now placed over the straw, and a covering of earth six or eight inches thick, is put over the whole and patted smooth with a spade. A small aperture should be left at the top of the hill, to assist in ventilation; or to be neater, a short oblong box may be inserted down to the potatoes, and the earth drawn nicely up to it. If a pole is used as the horizontal ventilator, the earth should be removed from below it, where it projects from the hill. All the apertures should be left open, for a few days after the operation is finished, and then only closed during severe weather, with a handful of pine leaves. Shelters should be erected over the hills to exclude the rain entirely. I consider it important to perform the whole business in dry weather. P. C. H.

Soiling Cattle.

Soiling is the feeding of cattle either in the barn or yard, through the summer, with new mown grass or roots.

The following are some of the advantages of soiling cattle over depasturing them:

"1. A spot of ground which, when pastured upon, will yield sufficient food for only two head, will abundantly maintain five head of cattle in one stable, if the vegetables be mowed in proper time, and given to the cattle in proper order.

"2. The stall feeding yields at least three times the quantity of manure from the same number of cattle; for the best and most efficacious manure is produced in the stable, and carried to the fields at the most proper period of its fermentation; whereas, when spread upon meadows or ploughed fields, as it is too common, and exhausted by the air and sun, its power is entirely wasted.

"3. The cattle used to stall feeding will yield a much greater quantity of milk, and increase faster in weight, when fattening, than when they go to the field.

"4. They are less subject to accident—do not suffer so much heat, flies and insects—on the contrary, if every thing be properly managed, they will remain in a state of constant health and vigor."—*Von Thaer.*

To Destroy Weevils in Granaries.

[*From the London Farmers' Magazime.*]

Sir—Seeing in your paper an inquiry respecting the destruction of weevils, I send a copy of a paragraph which has been cut out of some publication. It is as follows:—

"Accident has discovered to a French farmer a very simple mode of destroying weevils in corn warehouses; happening to lay in the corner of a granary in which there was a quantity of corn, some sheep skins with the fleece on, he was not a little surprised to find them, a few days after, covered with dead weevils. He repeated the experiments several times, and always with the same success. At last he ordered his corn to be stirred up, and not a single weevil remained in it."

I remain, sir, yours,
A CONSTANT READER.

Young Men's Department.

Chemical Catechism—Chapter IX.

[*From Parkes' Chemical Catechism.*]

OF SIMPLE COMBUSTIBLES—*continued.*

What is the origin of PHOSPHORUS?

Phosphorus is a peculiar substance, both of animal(1) and mineral origin. It was formerly obtained by a very tedious and disgusting process; but is now generally procured by the decomposition of the phosphoric acid, which is found in animal bones.(2)

What is the nature(3) *of phosphorus?*

Phosphorus is a solid inflammable(4) substance, which burns at a very low temperature, when in contact with oxygen gas or atmospheric air; and, when thus saturated with oxygen, it forms a peculiar acid.(5) It may be easily cut by the knife, and melts at 90° of Fahrenheit. Its specific gravity is nearly twice that of water.

What compounds are formed by means of phosphorus?

Phosphorus may be combined with oxygen, hydrogen, chlorine,(6) sulphur, or with most of the metals,(7) and also with some earths.(8)

What is the nature of these compounds?

Phosphorus forms with oxygen, according to the proportion of the latter, either oxide of phosphorus, or phosphorous acid, except it be saturated with oxygen, and then phosphoric acid; with hydrogen, phosphuretted hydrogen; with sulphur, phosphuret of sulphur, and sulphuret of phosphorus; with the metals, metallic phosphurets; and with some of the earths, earthy phosphurets.

What is the origin of CARBON?

Pure carbon is found only in the diamond; but it may be procured in the state of charcoal, by burning a piece of wood closely covered with sand, or any other convenient material, in a crucible, so as to preserve it from the action of the atmosphere.

What compounds are formed by means of carbon?

Carbon is capable of forming various combinations: it unites with oxygen, hydrogen, nitrogen,(9) sulphur or phosphorus, and with iron.

What is the nature of these compounds?

Carbon, with various doses of oxygen,(10) forms carbonic oxide, or carbonic acid; with hydrogen and caloric, carburetted hydrogen gas; with nitrogen and caloric, carburetted nitrogen gas; with sulphur, sulphuret of carbon; with phosphorus, phosphuretted carbon; and with iron, plumbago, or carburet of iron.

Some of these compounds having been already examined, it will now be expedient to consider the other states and combinations of carbon; therefore, what is charcoal?

Charcoal, which is the combination with which we are the most familiar, is the coaly residuum of any vegetable substance that has been burnt in close vessels.(11)

What are the characters and appearances of charcoal?

Charcoal is generally black, sonorous, and brittle; very light, and destitute of smell.(12)

What are the properties of charcoal?

Charcoal is a powerful antiseptic;(13) when ignited, it has great affinity for oxygen;(14) is unalterable and indestructible by age;(15) is a non-conductor of electricity, and a bad conductor of heat; and if air and moisture be excluded, is not affected by the most intense fire.

To what uses is charcoal applied?

In the preparation of gunpowder, charcoal is a most important ingredient; it is also employed in purifying rancid oils, and abstracting the color from sirups and many other valuable preparations; for decomposing the sulphuric salts, which it effects by absorbing the oxygen of their sulphuric acid and liberating the sulphur; and for so many other purposes, by the chemist and the manufacturer (16), that it would be impossible to enumerate them.

Is charcoal a simple, or a compound substance?

Common charcoal is a compound substance: it is an *oxide* of carbon, or the woody fibre partially oxidized; it also contains hydrogen, and a portion of fixed alkaline salt and some earth, but these are rather adventitious than essential ingredients. (17)

---

(1) The real origin of phosphorus is very obscure: some have supposed it to be a product of the process of animalization, and several curious facts might be adduced to strengthen this opinion.

(2) Phosphorus was accidentally discovered at Hamburg, in 1669, by an alchemist of the name of Brandt, in his search after gold; and two years afterwards, one Kraft brought a small piece of this substance to London, on purpose to show it to the king and queen of England. Mr. Boyle afterwards discovered the process, which he described in the *Philosophical Transactions* for 1680, and in a little book which he published in the same year, entitled *The Aerial Noctiluca.* Mr. Boyle instructed Mr. Godfrey Hankwitz of London how to procure it from urine, so that he was the first who made it for sale in England; and he continued to supply all Europe with it for many years. I have in my possession a scarce portrait, by Vertue, of this chemist in the midst of his laboratory, surrounded by his chemical apparatus; the form of which shows that even at that time they had the means of accurate analysis, if they had had a rational theory to direct them. From a Latin inscription, it appears that he had this print engraved to present to his customers on his taking leave of them, when about to enter upon his travels abroad to sell phosphorus.

The discovery of phosphorus proves that valuable discoveries may be made even by men who have no means of appreciating their nature. Stahl maintained that it was the *marine salt* contained in urine, which yielded phosphorus.

(3) Phosphorus, when taken internally, is poisonous. It is related in the *Annales de Chimie,* that a great number of domestic fowls and turkeys were poisoned, merely by drinking the water in which some newly made phosphorus had been washed. Though poisonous, it has been given in *small* quantities by some French physicians, in malignant fevers, to stop the progress of gangrene, in which it succeeded beyond all hope. (Nicholson's *Journal of Philosophy and Chemistry,* vol. iii. page 85.)

(4) If a piece of phosphorus be placed on the surface of water, a little below the heat of boiling, it will immediately inflame. This is one characteristic of phosphorus, and distinguishes it from all others substances. It melts at the temperature of 90°, and takes fire at about 148°.

(5) Phosphorus is used in forming phosphoric acid, in various chemical experiments, and in making phosphoric match bottles. These bottles may be prepared by mixing one part of flour of sulphur with eight of phosphorus. When used to procure light, a very minute quantity is taken out of the bottle on the point of a match. and rubbed upon cork or wood, which produces an immediate flame.

Phosphorus should always be handled with great care, lest any part of it get under the finger nails, a small portion of which might occasion great inconvenience.

(6) Sir Humphry Davy has formed two compounds with phosphorus and chlorine; the one is a white powder, composed of about one of phosphorus, and 6.8 of chlorine by weight, and which he calls *phosphorana;* the other is a fluid as clear as water, and its specific gravity is 1.450: he calls it *phosphorane.*

(7) Phosphorus will combine with all the metals except gold and zinc. It unites with iron, and forms that kind of iron called *cold-short.* Iron of such property acquired this name on account of its being very brittle when cold, though malleable when heated. Such iron may, however, be made good and fit for most purposes, by heating it with carbonate of lime. (*Annales de Chimie,* tome xlii. page 832.)

(8) Several species of animals have the property of emitting light. The light of the glow-worm is well known, but the *Pyrosoma atlanticum* has not been described by naturalists. M. Peron, on his voyage from Europe to the Isle of France, observed this animal between three and four degrees north latitude. Its phosphorescent quality, (as it has been called,) so truly prodigious, renders it one of the most beautiful of all known zoophites, and its organization ranks it amongst the most singular. The darkness was intense when it was first discovered; the wind blew with violence, and the progress of the vessel was rapid. All at once there appeared at some distance, as it were a vast sheet of phosphorus floating on the waves; and it occupied a great space before the vessel. The vessel having passed through this inflamed part of the sea, the crew discovered that this prodigious light was entirely occasioned by an immense number of small animals, which swam at different depths, and appeared to assume various forms. Those which were deepest looked like great red-hot cannon balls; whilst those on the surface resembled cylinders of red-hot iron. Some of them were soon caught, and were found to vary in size from three to seven inches. All the exterior surface of the animal was bristled with thick oblong tubercles, shining like so many diamonds; and these seemed to be the principal seat of its wonderful powers of emitting light. In the inside also there appeared a multitude of little oblong narrow glands, which possessed the same virtue in a high degree. The colour of these animals, when in repose, is an opal yellow mixed with green; but on the slight movement of those spontaneous contractions which it exercises, or those which the observer can at pleasure cause by the least irritation, the animal inflames, and becomes instantly like red-hot iron, and of a most brilliant brightness. As it loses its phosphorescence, (if this property be phosphorescent,) it passes through a number of tints successively, which are extremely agreeable, light, and varied; such as red, aurora, orange, green, and azure blue: this last shade is particularly lively and pure. A further account of this curious creature may be seen in one of the early volumes of the *Journal de Physique.*

(9) The compound formed by the union of carbon and nitrogen, is known by the name of prussic gas. It was discovered by Gay Lussac, and by him called *cyanogen.* It is obtained from prussiate of mercury by distillation. It is a permanent gas, very inflammable, and nearly twice as heavy as atmospheric air. It affects the nostrils violently when inhaled by them.

(10) Messrs. Allen and Pepys have lately shown that charcoal ought not to be considered as an *oxide of carbon;* for that, when well prepared, it requires as much oxygen for its combustion as the diamond; and that diamond, and all pure carbonaceous substances, differ generally from each other only in the state of aggregation of their particles. (See *Philosophical Transactions* for 1807, part ii. page 267.)

(11) Charcoal, for common purposes, is made by a less expensive process. The wood is disposed in heaps regularly arranged, and covered with earth, so as to prevent the access of any more air than is absolutely necessary to support the fire, which is kept up until all the water and oil are driven off; after which the fire is extinguished, by shutting up all the air-holes. A more economical method is first to collect the pyroligneous acid from the wood, by dry distillation in large iron cylinders; and then the residuum in the cylinder will be charcoal of the best quality. By this process, His Majesty's gunpowder works have for some time past been supplied with charcoal.

(12) Charcoal is so porous that it may be seen through with a microscope; and, however large the piece, it may be readily blown through.

(13) "All sorts of glass vessels and other utensils may be purified from long retained smells of every kind, in the easiest and most perfect manner, by well rinsing them out with charcoal powder, after the grosser impurities have been scoured off with sand and potash. Putrid water is immediately deprived of its offensive smell by charcoal." (See Crell's *Journal,* vol. ii. page 170.)

Meat which is only a little tainted with putridity, may at once be made sweet by charcoal; and if common raw spirits be agitated with charcoal, they will be deprived of their bad flavour. A gentlemen in the spirit trade, however, informs me that spirits treated in this way are very apt to resume the old flavour, if kept in the cask only a few months.

(14) Charcoal, from its affinity with oxygen, will decompose the sulphuric and nitric acids. It decomposes the latter with great rapidity. If the charcoal be dry and finely powdered, and the acid strong, and allowed to run down the inner side of the vessel to mix with the charcoal, it will burn rapidly, giving out a beautiful flame, and throwing up the powder so as to resemble a brilliant fire-work.

(15) "The beams of the theatre at Herculaneum were converted into charcoal by the lava which overflowed that city; and during the lapse of seventeen hundred years, the charcoal has remained as entire as if it had been formed but yesterday, and it will probably continue so to the end of the world. The incorruptibily of charcoal was known in tho most ancient times; the famous temple at Ephesus was built upon wooden piles, which had been charred on the outside to preserve them." (See Watson's *Chemical Essays,* vol. iii. page 48.)

"It is said that there still exists charcoal made of corn in the days of Cæsar, which is in so complete a state that the wheat may be distinguished from the rye." (Willich.)

"About forty years ago, a quantity of oak stakes were found in the bed of the Thames, in the very spot where Tacitus says that the Britons fixed a vast number of such stakes, to prevent the passage of Julius Cæsar and his army. They were *charred* to a considerable depth, retained their form completely, and were firm at the heart." (Dr. Robinson's *Introduction to Black's Lectures.*) The ancients wrote with levigated charcoal, the most indestructible substance we know of; and accordingly, the writings found in Herculaneum are still a perfect black. (Ib. vol. ii. page 480.)

Casks charred in the the inside are now used to preserve water in sea voyages; and such casks are found to preserve toe water uncorrupted. (Dr. Black's *Chemical Lectures,* vol. ii. page (285.

(16.) Charcoal is used by mathematical instrument-makers and engravers to polish their brass and copper plates. Plates of horn and lantern leaves are polished with it. It is also much used by artists in tracing the outlines of drawings.

(17.) Messrs. Allen and Pepys have lately determined by experiment that charcoal properly prepared contains no sensible quantity of hydrogen, but that it absorbs moisture if exposed to the air only a few hours, which renders the result of the analysis uncertain.

*Moneys received between the 20th of Sept. and 24th October, in sums of $5 and over. The total receipts are included from post-offices marked with an asterisk.**

MORUS MULTICAULIS AND OTHER MULBERRIES, &c.—The subseriber is now ready to receive orders to any reasonable amount, for trees of the Morus Multicaulis, or cuttings of the same. The trees are genuine, all being raised by the subscriber, either at his nursery here, or at his *Southern establishment at Portsmouth, in Lower Virginia.* Also, the Elata, Broussa, Canton and Moretti or Alpine, &c.

The collection of Fruits is of the most celebrated kinds. The catalogue of *Fruit and Ornamental Trees and Shrubs, Roses and Herbaceous Plants, for* 1839, is ready, and will be sent to all who apply. In that catalogue, the very best kinds of fruits, so far as proved, are particularly designated by a *star*. All orders will be promptly attended to: and trees, when so ordered, are securely packed for safe transportation.

Nonantum Hill, Newton, Mass. 7th October, 1839.
t jan. WILLIAM KENRICK.

FARM & COUNTRY RESIDENCE. FOR SALE, a very desirable Farm and family residence, most conveniently located, in a dry, airy and healthy situation, eight miles from Baltimore, half a mile from the Philadelphia turnpike, (one of the best roads in Maryland,) and the same from the post-office at Rossville, and Depot on the rail-road from Baltimore to Philadelphia, at Stemmer's Run. It contains 90 acres, of which about 30 are in wood, and the remainder partly in clover and timothy and natural meadow, and partly arable land, easy of cultivation, and kind for the production of all farm produce, fruits, vines and vegetables. The improvements consist of a new and excellent two story frame house, comprising a spacious hall and two parlours with folding doors, on the ground floor, and six good bed-rooms above, and large dry cellar under the whole. Also, a comfortable log-house, with cellar underneath, and buildings adjoining suitable for kitchen and servants' quarters, and a spacious Barn, Stable, &c. detached; a well with pump and springs of good water, and a fine young thriving apple orchard of 250 grafted trees, of the best kinds, some of which are now in bearing, and a few Peach, Pear, Plum and other fruit trees; the whole together forming a most eligible property, rarely to be met with. Possession may be had as soon as required, and for price (which will be low,) and other particulars, apply personally or by letter, (post-paid,) to Dr. C. STREATER, Rossville, Baltimore county, Maryland. nov.1t

---

POUDRETTE and URATE—AMENDED DIRECTIONS FOR THEIR USE—(For previous directions, see Cultivator, vol. vi. No. 3, p. 60.) Poudrette *is not* dissolved in water, before being used as is Urate, but is to be used in a dry state, or by mixing it with dry soil in hills or drills, or sown in broadcast on the land, as you would lime or ashes. Experiments in this country, thus far, have proved the following methods as the most advisable in its application.

For Corn—After the furrows have been struck, sprinkle in the place where the hill is to be, before planting, a handful of Poudrette, equal to about a gill, then deposite the corn, (*double that quantity of Poudrette has destroyed corn*, and burned it up,) then cover up the corn and press the earth down over it with the foot or hoe.

For Potatoes—The same quantity, namely, a handful or gill may be used very advantageously; and it has so happened, that when the quantity was increased nearly double, no injury resulted, but rather improved the potatoes, a large handful, however, is sufficient.

Compost—It is worse than useless to attempt to make compost by mixing Urate or Poudrette with any thing but dry soil: if mixed with other manures, they operate on the other manures until those manures are consumed, before they are beneficial to plants; and in some instances it may be, that the result of the Urate and Poudrette in the *first* year of their *first* application, will not be as satisfactory to the farmer as he will think he had a right to expect: this arises from the fact that the land contains a considerable quantity of some former manure, upon which the Urate and Poudrette will first act: at the very next season, however, the farmer will find a crop far superior to his expectation, provided he will put no new manure of any description to the land lately manured with urate or poudrette. This, however, must be further explained by saying, that it applies to manure placed or dunged in the hill, or where the land is in a high state of cultivation, from having been highly manured in broadcast, which would give the poudrette an opportunity of feeding upon or consuming it. Experience has proved, this year, that where there was a moderate application of lime or barnyard manure applied to the land in broadcast, it did not appear to affect the influence of the poudrette on the crop.

The quantity of poudrette must vary from 15 to 35 bushels per acre, according to the quality of the land, and the crop cultivated; less than 15 bushels to the acre may not be very satisfactory, and more than 35 is useless. On Long-Island, the following has been adopted by a practical farmer with success, viz:—For wheat, 40 bushels of poudrette per acre; rye 25 bushels; oats 20 bushels; buckwheat 15 bushels; Indian corn one gill in the hill.

Urate and Poudrette are light substances, and liable to be blown off the ground by high winds, if sowed on the surface when the ground is not damp; therefore, it is considered best to sow the grain and harrow the land once, and then sow the manure in broadcast and cross harrow the land the 2d time.

The difference of the season, between spring and autumn, and the state of the atmosphere, are to be considered before using either urate or poudrette; damp weather is always to be preferred. Neither of them contain any seed of weeds of any description. An application of 35 bushels to the acre of urate or poudrette once in every three years is sufficient.

Urate and poudrette may be sent to any part of the country in barrels or bags—barrels are to be preferred when it is liable to get wet. Orders may be given, post-paid, directed to "*The New-York Urate and Poudrette Company,*" box No. 1211, post-office, New-York.

The urate and poudrette made by this company, is not confined to distribution among its stockholders only, and therefore farmers and gardeners may expect a supply in the order in which their application is made, without any condition of becoming a stockholder, or advancing any more money than may be sufficient to purchase what they need.

Price of the Urate 50 cents and Poudrette 40 cents per bushel, with contingent charges for bags or barrels, &c. 1t.

DURHAM AND DEVONSHIRE CATTLE and SAXONY SHEEP, for sale by the subscriber.

1. The Bull *Memnon*, ftom the herd of F. Rotch, Esq. of Butternuts, N. Y. Pedigree No. 2,297, English Herd Book.

2. A four years old full blood Cow, a beautiful specimen of the Devonshire and Durham cross, with her calf, a heifer, six months old, by Memnon.

3. A bull calf, two and a half months old, by Memnon, dam Experiment.

4. From 70 to 80 Ewes, 40 to 50 Lambs, and 30 Rams, from my flock of full blood Electoral Saxon Sheep, selected by myself from the purest race in Saxony. H. D. GROVE,
oct.1t Buskirk's Bridge P. O. Wash. co. N. Y.

FOR SALE—TWO SOUTH-DOWN BUCK LAMBS.—The subscriber imported, in the fall of 1837, two ewes and a buck, selected from the Earl of Leicester's flock, (Holkham,) of which the above is the progeny. Near Dobb's Ferry, Pa. July 28, 1839.
Sept–tf JAMES A. HAMILTON.

SOUTH-DOWN BUCKS.—Two two year old very superior South Down Bucks, clothed with fine wool and long enough for combing, were imported last April, direct from England, from the flock of the late John Ellman, Esq. of Glynde, near Lewes, Sussex, and are for sale at one hundred dollars each, or to be let for the season at fifty dollars each, by the personal friend of the breeder.

OBADIAH ELLIOT.
Elizabethtown, N. J. Aug. 20, 1839. s3t

☞ The Genesee Farmer and Farmers' Cabinet, will give the above two insertions, and send bill to advertiser.

BERKSHIRE PIGS.—The subscribers are ready to receive orders for their fall litters of Berkshire Pigs.—Several of their sows will come in from the 25th of August to the 5th of September. Orders for the south can be sent to New-York every day in the week, (Sundays excepted,) and reshipped by a faithful person, without charge, except for freight to, or cartage in, New-York. Orders or letters of inquiry, *post-paid*, will receive immediate attention.
sept–2t. H. & J. CARPENTER, Norwich, Con.

IMPORTED CATTLE—BERKSHIRE PIGS.—The subscriber intending to return to England, offers for sale his stock of Imported Durham Short Horned Cattle and Berkshire Pigs, at his residence, English neighborhood, Bergen county New-Jersey, five miles from New-York. The stock consists of 15 head of milking cows, 1 two-year old heifer, 4 one-year old heifers, and from 8 to 10 spring calves. Four of the above cows are imported, and the remainder are got by the imported Herd-Book Bulls Dishley, Durham, Wye-Comet, Hall's Comet, Memnon, Admiral, Denton, &c.

BERKSHIRE PIGS.—Ten breeding Sows, in pig and with pigs by them at the present time; from 40 to 50 Pigs ready for delivery at any time, at prices from $10 to $20 per pair, delivered in New-York.

The imported Herd-Book bred bull Bloomsbury is with the Cows for the season, and from present appearance will soon all be in calf. The yearlings and spring calves are all by my bull Snow-Ball, late Minevis, by Wye-Comet, dam Nelle, bred by Israel Munson, Esq. of Boston, got by the imported bull Admiral; grand-dam Rosa, bred by Mr. Munson, by the imported bull Denton, owned by Stephen Williams, of Northborough, Mass.: great-grand-dam Tuberose, bred by Mr. Wetherall, and imported by Mr. Munson.

For further particulars, see Herd-Book; Dishley, page 63; Durham, page 567; Wye-Comet, page 200; Admiral, page 2; Denton, page 43; Tuberose, page 524.

BENJAMIN BRENTNALL, English neighborhood,
sept–3t. Bergen co. N. J. 5 miles from N. Y.

FOR SALE—The subscriber wishing to close up his business, offers for sale the valuable Iron and Lumber Establishment, formerly owned and occupied by Penfield & Taft, situated on Putts creek, six miles from Lake Champlain, in Crown Point, Essex co. N. Y. The premises in question consist of a valuable water power, with a fall of more than 100 feet within sixty rods; on which there is now in operation a Grist-Mill with three run of stones, propelled by an overshot wheel; two Saw-Mills, one with overshot wheel and double gear, all nearly new and in good order; a Forge with two fires; and a machine shop for pounding and separating ore. The water for propelling these works is held in reserve by four ponds or reservoirs on the premises; the upper one being about 2½ miles in length, forming an ample reservoir for the whole works below, and affording sufficient water in itself for driving a forge with four fires and a rolling mill.

Adjoining the works are **600** acres of land, one-fourth of which is under good cultivation; on which are five dwelling-houses, convenient barns and out-houses, a store, blacksmith shop, and buildings convenient for other purposes.

There is also **1,000** acres of fine timbered land lying two or three miles from the above described works. Also, about five miles distant are **800** acres fine timbered land, on which are two Saw-Mills, and one of the richest, most extensive and valuable beds of iron ore yet found in the U. States.

Also, **1,900** acres of land in the towns of Schroon and West Moriah, Essex co. the greater part of which is covered with pine timber; 100 acres of which is under good culture, and on which is a good saw-mill, blacksmith shop, several dwelling-houses, barns and out-houses.

Also, one-half of a farm of 130 acres, situate on Lake Champlain, near the mouth of Putts creek, 2-3ds of it under good improvement; on which there is a large and convenient wharf.

On examining the above described premises, they will be found to combine unparalleled advantages for prosecuting an extensive business in the manufacture of lumber and iron, and for the salc of ore.

Such parts or parcels of the premises as are necessary for prosecuting the manufacture of iron and the sale of ore, will be disposed of separately from, or in connexion with, the lumbering establishment, as may suit the purchaser.

For the terms of sale, and all further particulars, inquire of the subscriber on the premises. ALLEN PENFIELD.

ROHAN POTATOES.—Orders received for Rohan Potatoes, at $5 per Barrel, to be forwarded, as may be directed, without delay, by J. BUEL. tf

---

ROHAN POTATOES.—The subscriber is now prepared to furnish the above very valuable root for transportation, at $5 pr. bbl. until the 1st Nov. delivered at Albany. Persons living at a distance, will find it to their interest to forward their orders early, so they will reach their destination before cold weather sets in. Orders enclosing five dollars, (postage paid) or more, will meet with immediate attention.

CALEB N. BEMENT.
Three-Hills Farm, Albany, Oct. 1st, 1839.–3t

MULBERRY TREES.—25,000 Multicaulis, Alpine and Expansa Mulberry trees, and a few thousand Silk Worms Eggs, for sale by S. E. GIBBS & SON,
West end of Long-Island.
Address them at Brooklyn. October, 1839. 3t.

MORUS MULTICAULIS.—25,000 trees for sale, either in quantities or all together, and to be delivered at any time that may best suit the purchaser. They are from imported cuttings, of the genuine Morus Multicaulis, were planted in May last, and are of the most vigorous growth, measuring from three to five feet in heighth, with large collateral branches. Purchasers are invited to call and see them, at the residence of Gen. Morgan Lewis, Staatsburgh, Dutchess county, state of New-York, where the owner lives, as he thinks they will not suffer by a comparison, with any in the United States. Staatsburgh, Dutchess co. Sept. 11, 1839. [oct. 4t] MATURIN LIVINGSTON.

MULBERRY TREES.—A few thousand Mulberry Trees are for sale at the Albany Nursery. They consist of the Multicaulis, Brussa, Chinese, that is, the product of Chinese seed, and the common white. The prices will depend upon size and quality. The Brussa is more hardy than the common, and the Chinese about as hardy; and the three kinds are believed to be equal, if not superior, to the Multicaulis, for silk; though it is proper to add, none of the mulberries that we have tried are propagated with so much facility, from buds and cuttings, as the multicaulis. The prices will be conformed to the average market price. tf

---

ALBANY NURSERY.—This establishment now offers perhaps the best collection of Pears now in the country; [seo the June number of the Cultivator.] Also, Apples, Peaches, Plums, Ornamental Trees, Green-House Plants, &c. &c. A catalogue will soon be printed, and forwarded to order. Address J. BUEL & Co. post-paid. tf

---

THE SUBSCRIBER has located in Albany, where he is manufacturing his machines for thrashing and cleaning grain. He may be found at **53** North-Market-st. or at his machine shop on Patroon's Creek, near the Manor House. Sept. 2, 1839. [oct. 3t] JOHN A. PITTS.

ALBANY SEED STORE, GARDEN and AGRICULTURAL SEEDS, IMPLEMENTS, TOOLS, &c. kept constantly for sale at his Seed Store, 317 North Market-street, wholcsale and retail, consisting of a large assortment. It is the intention of the proprietor to test all seeds of which there is any doubt respecting their vitality, by sowing a few seeds in a small pot, before offering them for sale. And purchasers can test for themselves, any seeds of which they are distrustful, by sowing a few in a box of fine earth, and placing it in a warm room, exposed to the sun, where, if kept moist, the seed, if good, will vegetate in a reasonable time. In all cases where seeds prove to be bad, they will be replaced by others, or any reasonable satisfaction made. The proprietor has enlarged his establishment and increased his supplies, and with his experience in the business, together with his facilities for obtaining supplies, through Mr. GEORGE C. THORBURN, and his extensive correspondence and facilities for obtaining seeds, he flatters himself he will be able fully to meet the wishes and expectations of the public, and make the *ALBANY SEED STORE and AGRICULTURAL REPOSITORY* worthy of the high character it has already attained.

Persons ordering Seeds and Implements from a distance, with whom I am unacquainted, without remitting payment, are expected to give references in this city or New-York.
Sept–tf WILLIAM THORBURN.

FOR SALE—A Splendid Country Seat in the Highlands, on the Hudson River. That beautiful country residence, known by the name of the BEVERLY ESTATE, containing four hundred acres of land, about two hundred of which are fine level arable soil, of an excellent quality, in a good state of cultivation, and not surpassed by any on the river for fertility; the remainder is fine and thrifty timber land. The situation is the most eligible on the Hudson, extending one mile and a half on the river, with a bold shore and convenient dock, nearly opposite West-Point, and within fifty miles of New-York. The prospect is extensive and diversified, reaching from St. Anthony's Peak on the south, to the bay and city of Newburgh on the north. This estate can conveniently be divided into three farms, giving an equal proportion of front on the river, and of arable and timber land to each. Almost every enclosure is supplied with living springs of the purest water. There is on said estate a plain house, (formerly the head-quarters of Gen. Arnold;) also out-houses necessary to carry on the business of the farm. The single fact that during the whole time the cholera raged throughout the state, not one case occurred within ten miles of this place, is sufficient to prove the unrivalled salubrity of the situation. The facilities of intercourse with the city, that can be reached in four hours, by means of numerous steam-boats, are great, and daily increasing, both as regards pleasure, and the convenience of a near market for produce of every description.

For conditions of sale, apply to STEPHEN A. HALSEY, 189 Water-street, New-York, or RICHARD D. ARDEN, on the adjoining farm. Ardenia, 23d April, 1839. j6t

ALBANY, N. Y.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

Vol. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. NOVEMBER 20, 1839. No. 11.

Conducted by J. BUEL, of Albany.

TERMS.—One Dollar per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—Lewis Hill & Co. Richmond, Va.; Bell & Entwistle, Alexandria, D. C.; Gideon B. Smith, Baltimore, Md.; Judah Dobson, bookseller, D. Landreith, and M. S. Powell, seedsmen, Philadelphia; Israel Post, bookseller, 88 Bowery, Alex. Smith, seedsman, P. Wakeman, office of the American Institute, Broadway, New-York; Hovey & Co. Merchants' Row, Boston; Alex. Walsh, Lansingburgh, and Wm. Thorburn, Albany, gratuitous agents; John Thorburn, seedsman and general agent, St. Louis, Mo. E. Valentine, Johnson's Springs, Va. See No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

To our Patrons.

Being of opinion that the general wish of the public is that the Cultivator should be continued, and through the instrumentality of the friends of the paper, we would with great pleasure and satisfaction state, that arrangements have been made by which we hope to not only extend its circulation and usefulness, but to have it continued in the same *form* and at the same *price* as formerly. Arrangements having been made with Mr. Tucker, the present able editor of the Genesee Farmer, to discontinue his paper at Rochester and have it consolidated with the Cultivator under the same title at Albany, cannot fail to give to this paper a more wide and extensive circulation among subscribers, but will add greatly to its correspondents and contributors, thereby enhancing the value of the paper as a standard agricultural work of reference, and (we hope) giving general satisfaction both to the patrons of the Cultivator and Genesee Farmer.

Under these considerations we would refer our readers, more particularly our agents, to the prospectus of the union of the two papers, which will be found on our last page.

☞ We would inform our subscribers that the last or next number of this paper, with the index, &c. will not be issued till about the first of January.

Acknowledgments.

☞ We acknowledge the receipt of the second series of the School District Library, from the publishers *Messrs. Harpers & Brothers*, 82 Cliff street, New-York. Their advertisement, with the names of the selection of books contained in the series, will be found on our last page, to which we would respectfully request the attention and perusal of our readers.

The price of the first and second series which are already published, is twenty dollars each, including a case.

We also acknowledge the receipt of a Native Mulberry leaf from H. Wells, Esq. of Oxford, Ohio, measuring six inches across and nine inches in length, as large as any of the Morus Multicaulus we have seen. Mr. W. says he probably could have obtained one larger had he selected it before the frost destroyed them. He also mentions several varieties, which he says grow larger in his garden than the multicaulus. He does not give, however, any specific name for them.

Comparison of the Temperature of October 1838, and October 1839,

Large Calf.

A calf of the improved Durham breed, has been raised by Mr. Winant Younghans, of West Sandlake, Rensselaer Co. which, although but five months old, weighs 554 lbs.

Constitution of the New-York State Agricultural Society.

The style of this society shall be "The New-York State Agricultural Society;" its objects shall be to improve the condition of agriculture, horticulture and the household arts.

Section 1. The society shall consist of such citizens of the state as shall signify in writing their wish to become members, and shall pay on subscribing not less than one dollar, and annually thereafter not less than two dollars, and also of honorary and corresponding members.

The presidents of county agricultural societies, or a delegate from each, shall ex-officio be members of this society.

Sec. 2. The officers of the society shall consist of a president, four vice-presidents, a recording secretary, a corresponding secretary, a treasurer, an executive committee, to consist of the officers above named and three other members, of whom three shall constitute a quorum, and a general committee, the members of which shall be located in the several counties, and be equal to the representatives in the house of assembly.

The payment of fifty dollars or more, shall constitute a member for life, and shall exempt the donor from annual contributions.

Sec. 3. The recording secretary shall keep the minutes of the society.

The corresponding secretary shall carry on a correspondence with other societies, with individuals, and with the general committee, in furtherance of the objects of the society.

The treasurer shall keep the funds of the society, and disburse them on the order of the president or a vice-president, countersigned by the recording secretary; and shall make a report of the receipts and expenditures at the annual meeting in February.

The executive committee shall take charge of and distribute or preserve all seeds, plants, books, models, &c. which may be transmitted to the society; and shall also have the charge of all communications, designed or calculated for publication, and so far as they may deem expedient, shall collect, arrange and publish the same in such manner and form as they shall deem best calculated to promote the objects of the society.

The general committee are charged with the interests of the society in the counties in which they shall respectively reside, and will constitute a medium of communication between the executive committee and the remote members of the society.

Sec. 4. There shall be an annual meeting of the society on the Thursday following the second Tuesday of February at the capitol in the city of Albany, at which time all the officers shall be elected by a plurality of votes and by ballot. Extra meetings may be convoked by the executive committee. Fifteen members shall be a quorum for the transaction of business.

Sec. 5. This constitution may be amended by a vote of two-thirds of the members attending any annual meeting.

Address of Judge Buel,

Before the New-Jersey State Agricultural Society, held at Princeton, on the 10th of August, 1839.

Gentlemen:—The short notice I had of your meeting, and of your wish that I should address you on this occasion, together with my previous engagements, have prevented my being able to give you any thing more than a brief and imperfect sketch of what it would be my wish to state more in detail, and in a less imperfect form.

The earth every where abounds with the elements of human happiness and comfort. To man has been consigned, by a beneficent Providence, the capacity and duty of cultivating the soil, and of rendering these elements subservient to our wants and our highest enjoyments. And it has been wisely ordained, that our temporal reward shall be in a measure proportioned to the fidelity with which we perform our high duties to ourselves, our fellow-men, and our Creator. The cultivation of the earth was the primitive employment of man, when

> "Adam delv'd, and Eve spun."

It is still the great business among all civilized nations, and particularly so in our country. It ever must remain so, as it is alike necessary to our wants, our happiness, and our existence, as an independent people. All other arts and employments which distinguish civilized life, have grown out of agriculture. They are necessarily dependent upon it for support and existence. If agriculture were to cease, or to withhold her contributions, all other arts, and trades, and professions, would fail, the face of the earth would again become a wilderness, and man a savage.

A cursory survey of the present condition of the globe, will serve to satisfy us, that nations are enlightened and prosperous, and, I wish I could add, free, in proportion to the improved or neglected state of their agriculture; and that the other arts of useful industry prosper or decline, as this parent art is productive or unproductive. Spain, Italy, Asia Minor, and Egypt, have, in turn, been the granaries, in a measure, of the civilized world.—While their agriculture flourished, commerce and the arts flourished among them, and they were prosperous and powerful. But as the agriculture of these countries declined, or was destroyed by the inroads of hostile armies, by the arbitrary sway of despotic power, or the corrupting influence of commercial cupidity and extravagance, the physical and moral energies of these nations were broken down, and they became impotent and servile. Some of their once fairest portions have been made desert by the violence of man; commerce and the arts have fled to countries where agriculture flourished, and their population has degenerated into a miserable set of poor, ignorant, enslaved human beings, objects of pity and christian benevolence.

The intellectual and moral condition of a people, of a district, or even of a neighborhood, may also be pretty correctly judged of from the condition of its agriculture. For if the people are intelligent and wise, this intelligence will soon manifest itself in the improved condition of the soil—for knowledge is more efficient than animal power in the labors of the farm; in comfortable and neat buildings, and in chaste and extensive rural embellishments. If they are wise, they will find in rural labor their natural theatre of action, and the sure means of improving their circumstances, and of multiplying around them the pleasures and enjoyments of life. Where the mental and physical powers are so happily combined and employed upon objects so useful to themselves and to society, as those embraced by agricultural labor, there is but little inducement—little temptation—to immoral habits. But, on the contrary, where agricultural prosperity is most manifest, we are sure to find in the inhabitants a strong disposition to maintain a healthful state of morals, and to preserve in full vigor all the relative and social virtues which constitute the main ingredients in our cup of happiness. An improved state of agriculture not only promotes intellectual and moral improvement, but it tends to lessen the evils of pauperism and crime. These are generally the fruits of indolent habits, of body or of mind, which agriculture neither encourages nor permits. Although our population are five-sixths farmers, they constitute a lean minority both in our poor-houses and prisons. While they attend to the duties of their station, they are not likely either to rob or to beg to procure bread. Scotland has but few paupers, and Flanders less.

I need not remind this enlightened assembly of the important bearing which the condition of our agriculture, and of our agriculturists, has, and ever must have, upon our political destinies. The farmers of our country will be the last class to be corrupted by the bribes and blandishments of power—the last class to part with republican habits—to degenerate, under the baleful and enervating influences of extravagance, dissipation and fashion. The higher the condition of agricultural improvement, the greater will be the intelligence and independence of the agriculturist, and the stronger his inclination and his influence in perpetuating the virtues of our revolutionary fathers, and in maintaining in their purity, the institutions which they established, and in defending them by force, if need be, from foreign and domestic foes. Cherish, then, this interest, above all others. Enlighten it, encourage it, honor and reward it—for it is the palladium of your freedom.

Whether, therefore, we regard agriculture as a *necessary* branch of industry, indispensable to our wants; as a *natural* employment, adapted to the development and useful employment of our physical and mental powers; or in its influence upon the moral, social and political aspect of society, we find in it abundant claims to our highest regards, and warmest support.

If we look back in history to the first settlement of this country, we shall recognize, upon our Atlantic border, a rich and fertile soil, bountiful in the returns which it annually made to agricultural labor, and a contented and thriving population. If we look at the same country now, what is its aspect? Or, rather, what *was* its aspect forty years ago, before the spirit of improved husbandry visited our shores—before science had descended to enlighten the husbandmen in the principles of his business, and before the example of a better system of husbandry had begun to change our practice.—Millions of our once fertile acres had been worn out by reckless management, and thrown into old fields and commons, as unworthy, any longer, of culture; and tens of thousands of other acres, possessing equal, and in most cases, greater natural fertility, had been permitted to lie uncultivated and waste, for want of draining or embanking, a nuisance to the public eye, and the prolific source of disease and death. The farmers were growing poor—were degraded by ignorance and apathy—were seeking for more lucrative employments, or flying to the west, in search of new and unexhausted soils. No cultivated grasses, no alternation of crops, no economy in manures, no thorough draining, and but poor attention to farm stock, our lands were going down, down, down, in fertility, till many of them no longer paid for their culture. The character of the agriculturist sunk in a corresponding degree. Men shunned it as an unprofitable, irksome, and servile employment; and every young aspirant to fame and fortune sought to gratify his ambition at the bar, the counter, or even in the humble employments of life, rather than in the business of farming,

Let us now cast our eyes to the parallel history of agriculture on the old continent, and see what changes have taken place there, while our own soil was being deteriorated and exhausted of its fertility. I will cite for illustration, the husbandry of Great Britain, and of Flanders, though if I should carry the comparison into the German States, Holland, &c. the contrast might be equally remarkable and mortifying.

Great Britain has doubled, and her Scottish territory trebled, the products of their agriculture. The agricultural products of Great Britain now annually exceed, in amount, those of 1775, according to President Humphreys, three hundred and fifty millions of dollars; and yet, in the opinion of her most intelligent men, the British soil is capable of being made to double its present products.

Of Flemish husbandry, I will enter somewhat more into detail; because, in climate, in soil, and in the general make of the country, Flanders bears a close resemblance to the southern part of New-Jersey. The climate of Flanders is very similar to this; the surface of the country is flat, and was naturally wet and cold; the soil generally sandy and poor, except upon the streams coming from the interior, and at their embrouchere into the ocean. And yet, with all these natural disadvantages, there is probably no country in Europe richer in the products of the soil, owing principally to her excellent system of husbandry; and no where, apparently, is the condition of the agricultural population better—and the country more exempt from pauperism and crime, than in Flanders. Every acre, it is said, is made to maintain an inhabitant. This high state of improvement, it is true, has been the work of ages. But the sooner a work of improvement is begun, the sooner it will be completed, and the sooner it will return a profit on the outlay. The difficulties to be overcome in Flanders were great. In some cases, in order to lay the land dry, it was cut into small divisions, which were surrounded by deep trenches, to receive and conduct off the waters, and the surface graded so as to slope from the centres to the borders. In other cases seeds of larch were sown upon very poor grounds, to produce, by a process of years, a vegetable mould, from the falling foliage, sufficient to nourish a crop; and when this was obtained, the trees were cut down, and the soil subjected to careful tillage. These extraordinary cases are not stated for imitation, but to show the persevering labors of that industrious people.

The characteristics which distingush Flemish husbandry, and which have rendered it so uncommonly productive and profitable, are: a thorough draining of the land; a perfect pulverization of the soil, by frequent and deep ploughings, or by trenching; the subjecting the lands to alternate husbandry; the extensive culture of clover, of root-crops, and of tares, for soiling and winter feeding their cattle; the careful extirpation of all weeds; a remarkable attention to the saving, and a judicious application, of manures, particularly of liquid manures; a constant occupation of the ground with crops or herbage; and a judicious rotation, differing in almost every district, on account of the difference in soil, and adapted and settled, after long experience, such as is best suited to the local market—as will best repay the farmer's cost and toil by an abundant return—best cultivate the soil for a succeeding crop—best enrich it for the purpose of increasing fertility, and most effectually prevent, by judicious alternation, that natural disgust which even good soils manifest to reiterated crops of the same description; the small size of farms, and the keeping them in constant crop, no man attempting to manage more than he can manage well; the cutting of the forage, and grinding the grain, for farm stock, thereby greatly lessening this heavy item of expenditure; and, finally, the farmers giving their undivided attention to their farms, and their industrious frugal habits of living—no lumbering, no fishing, no speculation, no hankering after office.

I will take the liberty of making a brief comparison here, of the products of Flemish and Scotch husbandry, on the one hand, and of American husbandry on the other, in some of the staple productions of both continents, as the former were rated twenty, and the latter forty years ago.

The Rev. Mr. Radcliffe, who was sent to Flanders for the purpose of studying its husbandry, stated the average product of its soil to be—in wheat, 32 bushels; rye, 32¼ do; oats, 52 do; potatoes, 350 do, per acre.

Sir John Sinclair, whose reputation and veracity are well known, in his Code of Agriculture, states the average product of Scotch agriculture in good soils, as follows: wheat, 32 to 40 bushels, barley, 42 to 50 do; oats, 52 to 64; turnips, 30 tons; clover, three tons; and potatoes, from 8 to 10 tons; or, allowing 60 lbs. to the bushel, from 266 to 333 bushels.

Mr. Strickland, an eminent British farmer who resided some time in Maryland, and who travelled much in the United States, 40 or 50 years ago, in a communication to the British Board of Agriculture, stated our average wheat crop at 12 bushels the acre, except in the county of Dutchess, in New-York, where he allowed it to amount to 16 bushels the acre.

Gen. Washington, in 1790, in a letter to Sir John Sinclair, computed the average crop in Pennsylvania, which he then considered the best cultivated state, as follows:—wheat, 15 bushels; rye, 20; oats, 30; Indian corn, 25; potatoes 75.

It will readily be perceived from these estimates, that our acreable products were not half as great as those of Flanders or Scotland; or, in other words, that a day's labor on the farm did not effect half the benefit here that it did there. Was this owing to any natural infertility in our soil? Certainly not. Nature had been equally bountiful to both continents. But we *had* abused and wasted her bounties, while they had preserved and improved them. Our decrease grew out of a bad system of farming; their increase resulted from a more rational and improved system. The disparity arose from the science which guided labor in one case, and the want of it in the other—to that science which is still courting our acquaintance, and which we must become familiar with and apply, if we would profit largely from those privileges which God has bestowed alike upon us all.

But the sombre picture of our agriculture has undergone material changes for the better within the last forty years. In many districts, and on particular farms, the fertility of the soil has been renovated; draining has been commenced; manures have been better economised and applied, and new materials of fertility discovered and employed; root culture has obtained a footing; artificial grasses have been cultivated; our herds and flocks have been better selected, and better fed; new labor-saving implements have been brought into use; the alternating system has been adopted to a considerable extent; and last, though not least, the principles of agricultural science have been more extensively diffused, better understood, and more generally applied, and a knowledge of the improvements and better practices in farming promulgated through the instrumentality of our agricultural periodicals. Wherever these innovations upon ancient practice have been made, a corresponding benefit to the cultivator, and to the neighborhood, has been palpaple; lands have been enhanced in value; the husbandmen has increased his wealth, and advanced in respectability and usefulness, and every department of business has felt and acknowledged the vivifying influence of the happy change.

I have seen large tracts of land, in the valley of the Hudson, originally fertile, so worn out by bad husbandry, as to be thrown into old fields and commons, and thought unworthy of culture.

I have seen many of these same lands, in a period of thirty years, again restored, by good husbandry, to their natural fertility, and selling, for farming purposes, at one hundred, and one hundred and twenty dollars an acre.

It is to accelerate these improvements in the cultivation of our soil, that agricultural associations have been formed, and are forming, in every part of our country; and where they have been conducted with spirit, and with a view to public improvement, they have been eminently useful. It is to co-operate in these praiseworthy efforts, that the Association, which I have now the honor to address, has been established. It CAN do much in the good cause— it WILL do much in dispelling the clouds of prejudice and ignorance, which still overshadow our agricultural operations, and in diffusing light and knowledge and laudable emulation—if its members will persevere in the philanthropic determination, which I trust has brought them together—of rendering a substantial service to others, as well as to themselves.

Let us, for a few moments, descend to particulars. I think I have seen, on my passage, at various times, through New-Jersey, much land under culture, that does not give, what may be termed, half a crop, and which can hardly yield a nett profit, above the expense of ordinary labor and charges; but which might be made to yield, under the Flemish, or Scotch, or improved American system of management, a handsome income to the proprietors. Let us suppose that it would require an outlay of fifty dollars an acre, in draining and manuring, to bring thousands into a highly productive state, as productive as are now the soils in the land of promise—upon the borders or in the valley of the Mississippi—and I believe this is a very liberal allowance for the outlay—the interest of this sum would be three dollars an acre per annum. To offset against this three dollars a year, the proprietor or cultivator would probably receive an additional ten or fifteen bushels of wheat, an increase of his corn crop of twenty or thirty bushels the acre, and of other crops in proportion. A difference of ten or fifteen dollars a year, or even of five dollars, in the acreable profits of a farm, will, in a few years, make a wonderful difference in the condition of the good and bad farmer. The labor upon a good soil is no greater than that required upon a bad soil; while the pleasure of working the former, admits of no comparison with the disgust which one feels in working the latter. Does any one fail to see, in this estimate, the palpable benefits which would result from the limiting our capital and labor to the acres that we can cultivate well?

I could give many individual illustrations of the fact that I am now assuming, viz: that capital and labor may be more profitably expended in cultivating a few acres well, than in cultivating many acres badly. I will mention but a few; for no gentlemen present can have failed to notice the vast disparity in profits between well and ill cultivated farms.

A farm of 400 acres, naturally excellent wheat land, in the vicinity of Geneva, N. Y. had become so exhausted by the *skinning system*, that the owner thought he obtained a good price when he sold it at $10 the acre, or for $4000. The purchaser happened to be an intelligent Scotch farmer. With lime, sheep, and manure, and Scotch management, in ten years he so raised the value of these lands, that he was offered $100 the acre, or $40,000 for the farm. He declined the offer, declaring that it gave him a nett income, over the charges and expenses of his family, of $4000, or ten dollars an acre, equivalent to the interest of $150 an acre. And Mr. Robinson, the present proprietor, considers his improvements as but well begun.

A Mr. Harris, near Poughkeepsie, lately gave a statement of the farm produce actually sold from his farm in one year, which, after deducting the moneys laid out for labor, &c. left him an annual income of more than 17 dollars an acre on every acre of his farm. His farm, forty years ago, would not have brought over $25 an acre. It would now sell for $125 an acre.

The sandy lands of Kinderhook plains, which, in my recollection, sold from three to seven dollars an acre, now sell at 60 or 70 dollars an acre, in a state of modern improvement.

Mr. Merritt, of Dutchess, purchased 64 acres of land, which then maintained one yoke of oxen, two cows, and one pair of horses. It now maintains two pair of horses, one yoke of oxen, four cows, twenty hogs, and two hundred sheep.

Mr. Hawkins, of the Shakers Society at New-Lebanon, a few years since bought of the now President of the United States, the half of a farm of 240 acres, the whole of which then cut but twenty-five tons of hay.—By manuring and good management, he is now enabled to cut on this half 120 tons of hay, and to keep in tillage some acres more than is appropriated to arable crops on the other half.

Cases have been cited, by highly respectable authorities, of instances in Pennsylvania, Delaware, and Maryland, of lands, once poor, being made to yield an income equal to the interest of 200, 300, and even 500 dollars per acre. I feel warranted in saying, from what I have seen and heard, that every tolerable good acre of land, lying contiguous to navigable waters, to market and manure, may be made to give an income of fourteen dollars—thus giving to the land an intrinsic value of $200 per acre.

If a man has five hundred dollars, which he wishes to expend upon a dwelling for his family, would he be wise or prudent in exhausting his means upon the *frame* and *covering* of a *large* building, or upon the *frame, finish* and *furniture* of a snug neat dwelling, which should afford room enough and be infinitely more comfortable than the big house, even were it finished and furnished to his mind? No one will hesitate to say, that the five hundred dollars ought to be expended upon the comfortable, in preference to the large house. Apply this principle to agriculture. A farmer had better expend his five hundred dollars in bringing a *small* piece of land into high and profitable culture, than to waste it upon a *large farm*, which he does not, or cannot, cultivate well, and which netts him mere nominal profits. Capital and labor are the true sources of wealth. If concentrated, they produce, in agriculture, as in every other business, a more potent effect than when they are divided, and spread over a broad field of operations. It is not the number of men that constitutue the efficiency of an army; but the intelligence and skill of its leader, and the subordination and discipline of the corps. It is not the extent of lands that determines the farmer's profits, but the intelligence and skill of the master, and the high state of culture to which he brings them. The profits on fifty acres, well managed, are often greater than the profits of hundreds of acres badly managed.

The farm I occupy was naturally as poor, and as forbidding in appearance, as the poor lands of New-Jersey. It was considered a barren sand; and I became the butt of ridicule to some of my acquaintance, for attempting to bring it under profitable culture. It was a lean sand, abounding in springs, swamps, and low wet grounds.—In twenty years, however, it has assumed quite a different appearance. It is now worth $200 an acre for farming purposes; that is, it netts me more than the interest of $200 per acre. My average acreable product in corn is 80 bushels; in grass, nearly or quite 3 tons; in potatoes, in favourable seasons, 300 bushels; and my other crops are in proportion. And these crops are grown at less expense, for culture, than they can be on lands that are more stiff, and naturally more fertile. These improvements, it is true, have required a considerable outlay of capital, in draining, clearing, manuring, and in some portions to the extent, probably, of $50 the acre. Without the outlay, these reclaimed lands were valueless; with it, they are highly productive, and give me a liberal per cent on the money expended; and I have no doubt I could readily sell for cost and charges. I beg to be pardoned for this allusion to my own farming. I make it merely in confirmation of the fact, that sandy, wet lands, can be profitably reclaimed and cultivated, on this, as well as on the old continent.

Money is the sinew of agricultural improvement, as well as of war—with this difference, that agriculture is the parent of plenty, and war the cause of misery and want. Capital no where makes a more sure, and not often a more liberal return, in the end, than when judiciously applied to agricultural improvement. It is like the seed we commit to the earth. If there is no seed there can be no crop. If there is no outlay, there can be no return. And when there is not both seed and outlay, the product must be small indeed.

It remains for me, gentlemen, to suggest some of the means which present, for giving efficiency to your efforts, to improve the agriculture of your State, and, with it, the moral and intellectual condition of its population; for I consider the culture of the soil and the culture of the mind reciprocally acting upon and benefitting each other. The mind must be enlightened before the soil can be greatly improved; while the improvement of the soil will afford the best facilities for improving the mind, and the strongest inducements for the formation of moral habits.

I have said that the members of this Society *can* do much towards effecting these great objects of improvement; and they can do so both in their associate and individual capacities—if they will persevere in their intention to do a *public* good. And this, after all, to a greater extent than is generally imagined, is the best way to promote, if not one's individual gain, at least his personal happiness. There is a pleasure in the consciousness of having contributed to the prosperity of those around us—of having fulfilled, if only in part, this great duty of life: which neither wealth nor distinction, without it, can ever impart. A man who is surrounded by idleness and poverty, and by their usual concomitant, vice, be his business what it may, has, to say the least, but a bad set of customers, and enjoys but few of the pleasures of social intercourse; but, if surrounded by an intelligent, industrious, thriving, agricultural, population, he derives a profit, directly or indirectly, and a pleasure, from them all; and if he has been particularly instrumental in producing or maintaining this happy state of society, I don't know what higher pleasure he can expect or desire in his social relations of life.

The members of this Society may do a public good in either or all of the following ways:—

1. *By the stimuli of personal example*—of doing themselves what they would commend in others—in the family, on the farm, and in society. Mere theory is but speculation. In agriculture, it involves expense and uncertainty. But theory, confirmed and illustrated by practice, if it has merits, is a treasure, which all who see can appreciate, and which few who do see, will fail to profit by. A good farmer, therefore, is a help, and a wholesome stimulus, to all around him.

2. *By the stimuli of competition*, to be excited by the hope of distinction and reward. Competition in agriculture calls into exercise our best powers; which, when once successfully put into action, seldom flag, or fail to lead to the best results. Improvements are progressive; and where we have made one improvement, we have learnt an important lesson, viz: that we can improve. This fact once impressed upon our minds, both ambition and interest impel us forward. Had we not been stimulated by competition, to make the first effort, we should never have made a second, or a third, and should have believed, as thousands now do, that because we were brought up on a farm, there is nothing further for us to learn. Revolutions in agricultural improvements, as is said in political matters, never go backwards.—The great object is to give the first impulse. This the hope of distinction and reward are admirably calculated to effect.

3. *By the diffusion of agricultural knowledge.* There is no intelligent farmer, who will fail to profit by the better practices of his neighbours. Agricultural journals extend his neighbourhood, in this respect, over the Union, and, in truth, over Great Britain also. Every important improvement, and successful practice in husbandry, will be found recorded in these journals; and although they may contain much speculative matter, there is always enough that is useful, sound, and available, to at least thrice compensate him for the price of his subscription. And those, too, who profit from the communications of others, will find pleasure in communicating whatever may occur in their own practice which is likely to benefit the public, and also in promoting the circulation of agricultural journals among their neighbours and friends.

4. *By endeavoring to introduce the study of the principles of agriculture into our common schools.* Youth is the season to sow the seeds of useful knowledge—to instil principles which shall govern in maturer years.—And where these principles are timely and properly taught and inculcated, there is but little doubt they will expand into usefulness. Education gives the impress to manhood. It makes the professed Christian, Mahometan, or Pagan; it makes lawyers, doctors, or farmers; it makes the idler, the vagabond, the libertine, or the prudent, moral, industrious citizen. As the twig is bent, so will the tree incline. Every effort that is made to diffuse agricultural science, will tend to render its pursuits more lucrative, more honorable, and desirable, and to benefit society in a corresponding degree. We want professional schools of agriculture, but, till we have them, common schools may be made a tolerable substitute for teaching the elementary principles of the art.

And lastly, *by procuring for agriculture the patronage of the legislature.* If there is one business more important to the prosperity of the state than another, it is agriculture. If there is one interest that can be more benefitted by legislative patronage than another, or whose interests it would seem the bounden duty of the legislative councils to foster and promote, than another, it is agriculture. This branch of labor gives employment to a great majority of your population; it supplies the necessaries of life, and is the good source of public and private wealth and happiness. But government alone, be it ever so minded, can do but little to advance agricultural improvement, without the active co-operation of the people. We must put our own shoulders to the wheels before we call upon Hercules for help. And it is matter of history, highly creditable to the learned professions, as they are denominated, that they have always been among the most active and efficient in promoting agricultural improvement, from the circumstance perhaps, of their better appreciating its public advantages: and, also, that they go to work without the prejudice and conceits, which are apt to hang, like the nightmare, about those who have been farmer bred, and which prevents their going ahead in improvement. The founder of the Highland Society, of which I shall speak further, was a lawyer, by the name of McDonald. Most of the agricultural works which have issued from the British press, and which have eminently contributed to advance that nation, as well as ourselves, in agricultural improvement, have been written by clergymen, physicians, and lawyers, who were practically engaged in the business of farming. And in our own country, the greatest stimulants to improvement, and some of the best practical lessons in husbandry, have been given by men of enlarged views, and liberal minds, who have been brought up to other pursuits, but who have taken up farming, as a source of pleasure, or of profit, at a maturer period of life. Enlist, therefore, by all means, men of all classes, and particularly those of enterprise, wealth and influence, in your laudable undertaking.

For your encouragement and example, gentlemen, in the work you have resolved upon, I beg to direct your attention, for a few moments, in conclusion to what I have to offer to Scotland, and to her agricultural society; to Scotland as she *was*, and to Scotland as she *is*, in her agriculture; and to the small beginning of her society, to the measures it has pursued, and to the splendid and happy results that have crowned its labors.

And first, to show what Scottish husbandry *was*, I will quote from the Edinburgh Quarterly Agricultural Journal, the best periodical of the kind, perhaps, now, or ever published.

"To say what was the state of agriculture in Scotland, at the date of the formation of the Highland Society," says this journal, "would, to treat of it minutely, require greater scope than the limits of a periodical would admit. * * * But, to take one sweep over hill and dale, over corn field and meadow, we may at once pronounce the agriculture of Scotland, at that period, to have been wretched—execrably bad in all its localities! —Hardly any wheat was attempted to be grown; oats, full of thistles, was the standard crops, and this was repeated on the greater part of the arable land, while it would produce twice the seed thrown into it; turnips, as part of the rotation of crops, were unknown, few potatoes were raised, and no grass seeds or clover were sown. The whole manure of the farm being put on a little bit of the best ground, near the farmstead, where they grew some barley of the coarse sort, termed 'bere,' wherewith to make bannocks, or small beer, or peradventure, if the farm lay at the foot of the Grampians, to brew a portion of 'Mountain-dew.' Since the writer can recollect, a great part of the summer was employed in the now fertile shire of Fife, in pulling thistles out of the oats, and in bringing them home for the horses, or mowing the rushes or other aquatic plants, that grew on the bogs, around the homestead. Such *was* the state of Scotland, with but little appearance of amendment, up to 1792."

In 1815, the scene had greatly changed. In the low country, "beautiful fields of wheat were to be seen—drilled green crops, and clean fallows every where abounded,—the bogs had disappeared,—the thistles no longer existed. Soon after this the farmer could grow turnips to any extent, and the bare fallow was exploded. The Deanston system of draining, and deep ploughing were introduced; 'wet lands were made dry, poor weeping clays were converted into turnip soil,' whole parishes were transformed from the unsightly marshes, into beautiful and rich wheat-fields; and where the plough could scarcely be driven for slush and water, were to be seen heavy crops per acre, and heavy weight per bushel." Scotch agriculture has since been progressively improving, until, as I have before stated, its average products probably double those of this country.

Secondly, of the Highland Society, its origin, its operations, and its present extent, and means of usefulness.

"In 1784," says our authority, "a few gentlemen, full of zeal for their country, and it may be a little love of society, formed themselves into a hole and corner club, in a coffee house, called the Exchange, situated in the court of that name, near the 'market cross of Edinburgh.' Here, in the enjoyment of agreeable conversation, and perhaps a good supper, did those worthies talk over plans for the amelioration of the Highlands, and from this nucleus arose the now widely extended and powerful Highland Society," whose members now number twenty-three hundred, and whose, premiums, for the current year, exceed seventeen thousand dollars.

"In the days of its youth and feebleness, the Highland Society, sent the leaven of turnip husbandry into all the glens and straths of the north, by offers of small prizes to certain Highland parishes, and the same may be said as to the growth of clover and the finer grasses. As it advanced in strength, as to numbers and cash, attention was turned to premiums for stock; then came offers of reward to men of science to discover better implements and machines, to diminish friction, and consequently draught, such as in the threshing mill and other parts of agricultural machinery, Still advancing in the scale of intellect and of science, premiums were offered for essays to bring to light the facts connected with chemistry and natural philosophy; and, under the auspices of the society, was set up the Quarterly Journal of Agriculture, a work which has been the vehicle of conveying so much useful information to the agriculturist, that, we humbly venture to say, it ought to appear on the table and book-shelf of every farmer's parlor. After this, the great stock shows were resolved upon, as another link between the society and the practical farmer, at the same time throwing aside all paltry feeling, and making them open to stock upon both sides of the Tweed (English as well as Scotch.) Nor has the society forgotten the beauty of the country as the premiums offered in regard to planting trees, and the such like subjects testify; and to sum up all, it may be said, the Highland Society has been a '*point de appui*,' a rallying point to which the agriculturist of Scotland, might look, and a fostering mother to all who, although strong in talent, were too weak in interest, to make it public."

May the spirit and wisdom which have animated, and guided the Highland Society of Scotland, animate and guide this institution; and may your success and usefulness be as brilliant, as wide spreading, and substantial, as have been theirs.

I have thus endeavored, gentlemen, to show the practicability and importance of improving your agriculture, and have suggested some of the means by which this society may efficiently co-operate in the great work of improvement. The work is a noble one, worthy the philanthropist and the patriot. Its objects are the good of our country, and the happiness of man. And though you may not reach the goal of your wishes, your labors will not be lost. The seed which you sow will produce its tens and its twenty fold, though you may not live to gather the harvest. The work of improvement which you begun, will progress, and be fraught with blessings to your children and your state. And you may be sure of a liberal reward for your exertions, at least in the conscious pride, which every good man feels, in having faithfully performed a high duty to society.

CORRESPONDENCE.

The Tariff—Balance of Trade.

Sing-Sing, September 23, 1839.

Friend Buel—It appears to me that there are a great many vague notions entertained in the world respecting the effects of a protecting tariff, as it is called, and the balance of trade. A great many specious arguments are made use of, to show how easily we might, by legislative enactments, grow rich; although the way, to my mind, has never been very clearly defined. My views of the subject are the result of reasoning on general principles. I assume, in the first place, that the only real increase in the wealth of a nations consists in those improvements which go to increase production, or which are of permanent utility, such as the improvement of the soil in agriculture, the improvement of machinrey in mechanics, the construction of canals and rail-roads to facilitate the exchange of property, or the erection of buildings of good materials where there has been none before. These are the principal means of increasing the wealth of a nation, and I think they are most available where trade is left unfettered. I think all must admit that the greatest desideratum is, that we may enjoy the greatest amount of the good things of this world for a given amount of labor; but it does not follow that, that enjoyment must alone consist in eating, drinking, and wearing yearly the amount of a year's labor. On the contrary, it consists in part in the making of such improvements as I have mentioned, which is as it were enjoyment put at interest, that it may be increased at some future day. Now the question is, under what system will we advance fastest in national wealth? Some say let us have a high tariff, and manufacture all that we can for ourselves; that will enable us to make our exports more valuable than our imports, and the balance in our favor will be that much added to our national wealth. Well, unless we get the balance in some shape, we should be the losers: If we take it in goods, we gain nothing, *as most people think*, for then there would be no balance; if we take it in specie, it will not add to our real enjoyment so long as we keep it, and not until we exchange it with other countries for something we can eat, drink, wear, or use in some other way, and that leaves us where we begun, Here some one more keen-sighted than his fellows may interpose and say, let us take the balance in specie, and apply it to the construction of works of internal improvement, instead of borrowing foreign capital. I answer, if we do, that puts the money in circulation, and this nation's portion of the currency of the world is limited by the laws of trade; consequently it would flow out as fast as it flowed in: That would make our exports and imports of specie balance each other, and the result would be precisely the same as though we imported no specie and exported none; and that which we have supposed to be applied to works of internal improvement, had been borrowed out of money already in circulation. Therefore the idea of getting rich by exporting more than we import, is altogether preposterous, unless we can get foreigners to pay us interest on the balance; but we have more cause to borrow than lend.

All classes are to be fed, clothed and provided for;

but it does not follow that the whole time of a whole people is to be employed for that purpose. Tariff or no tariff, a part of our time can be and is spared, in which to make improvements; but, if we can exchange the produce of forty days' labor in agriculture, for as much of foreign goods as we would have to give forty-five days' labor for to domestic manufacturers, we save the one-ninth part of our time for other purposes; or what would amount to the same thing, the one-ninth part of the people might be engaged *all* the time in making improvements, which would be adding capital to the nation. The true policy with nations, as with individuals, is to sell where they can get the best price, and buy where they can buy cheapest. I believe it to be an error of opinion, that for the want of a higher tariff, excessive importations are made: I attribute it to an unstable currency. Our measure of value is too much like what a measure of length or quantity would be, if made of India rubber: it is altered too easily at will. If prices are artificially inflated, excessive importations will naturally be made from countries where prices are lower. Domestic manufacturers, in such cases, cannot compete with the foreign; and it is said to be for the want of a higher tariff. A higher tariff laid when excessive importations are making, would no doubt check them for a season; but let it be considered that under a tariff system the country can bear more currency than if there was no tariff, because a tariff for a limited time protects money from exportation, by keeping out foreign goods which would create a demand for it; and the amount of currency may and will be increased, until prices are so high that we can import foreign goods over the tariff, pay the duties, and still have a profit. A tariff, then, after a limited time, is no protection at all, unless we go on increasing it ad infinitum, which would never do. It would be a protection, if, under its operation, prices did not rise. If it *was* a protection, it would still be bad policy. Government should undertake to effect nothing more than to *start* manufactures into existence, where the condition of the country will warrant their continuance, without taxing the people to support them; and that, in my opinion, can be effected in no way so well as by offering a direct bounty, such as now with propriety might be given for a limited time for the production of silk.

Many people think, that without a tariff, foreigners would sell to us of their wares, and might not be willing to take our produce in exchange. If they did give us something for nothing, we should certainly make more out of them without a tariff than with; if they drew specie, it would not last always; if they refused to trade with us, they would lose most, and it would be the most efficient tariff the American System men could ask for. In the natural course of things, a nation's exports will be equal to its imports, and vice versa; and it is right that it should be so. If this nation's exports are less than its imports, it is for two reasons: One is because of the emigration to this country, which brings wealth in its train to the amount of many millions annually. Another great cause of our importing more than we export of late, may be found in the fact that the States and corporations are loaning money in Europe by the millions, for banking purposes and works of internal improvement. These loans, I believe, generally come to this country in the shape of foreign goods, the avails of which are paid here to the borrowers. For that portion of our imports we export nothing but a mortgage on posterity; and it gives to the country a seeming prosperity, similar to what a man evinces when he is sporting on borrowed money, and like to what some inebriates feel when they are *pretty considerably well corned;* and I fear that with some States, the languor of depression will come in the shape of feeling in the pockets for *direct* taxes to pay the interest. If the loans came to this country in gold and silver, it would inflate prices by putting it in circulation—that is certain: If they came in goods, prices may be raised to the same pitch by an increase of currency, without turning the exchanges against us, and the banks have not been slow in filling up the vacuum. The consequence of the States borrowing so much foreign capital in a short time, has been an increase in the cost of their improvements; because producers are fewer, provisions higher, and labor scarce and dear. It would no doubt have been cheaper for them to have constructed their works more gradually, and to have raised their money at home, even though they had been obliged to pay over seven per cent interest. By borrowing a portion of the money already in circulation, the prices of provisions and labor would have remained nearly stationary, instead of rising to the enormous height which they have of late years, in an expenditure of thirty millions of dollars a year: More than one-fourth the amount need not have been out of circulation at any one time, and we should have had the satisfaction of owing it to our own citizens instead of foreigners, besides preserving us from those habits of extravagance invariably engendered by an artificial inflation of prices; which habits must be changed, I am thinking, before we pay off both principal and interest.

It may seem strange and paradoxical that the States borrowing too much money in England of late should be the cause of the present scarcity of money here, when the natural tendency is to make it more plentiful. If we may credit late English papers, much of the proceeds of the sales of American stocks has of late been shipped to the Continent, to pay the debts due by American merchants there. The specie was drawn from the Bank of England, until the managers found it necessary to curtail discounts to such a degree as to compel English merchants to call on their American debtors for *real money,* in payment for a portion of the goods imported under the presumption that they would be paid for by increased sales of States stocks. It is also said that English warehouses are full of goods designed for the American market, which will be sent here and sold for what they will fetch, to the great injury of American manufacturers.

You will perceive that I consider the tariff a deceptive thing; getting rich by the balance of trade, an illusion; and borrowing so much money in Europe, very impolitic and unstatesmanlike, to say the least of it. It is not high prices at home that makes a nation rich; but it is the facility with which men and communities of men can exchange the products of their labor for articles which they stand in need of, under a scale of steady prices which admit of calculation and foresight in business.

With great respect, I remain your friend,

JESSE RYDER.

Best Season for Destroying Bushes.

Greene Co. Va. July 15th, 1839.

J. Buel, Esq.—Sir,—In the last number of the Cultivator, I see, by you, an answer to a query of the most effectual time to cut bushes, sprouts, timber, &c. to kill them, and whether or not the moon has any influence as to time. You seem to think that the moon has; consequently recommend the old moon in August, from popular opinion and your own experience. And you give farther as a reason, that at that time there is less sap in circulation than in the other summer months; and farther, the intense heat of the season tends to destroy vitality. As to the heat, that is a good reason, and I would add dryness of the season generally in August, for I have frequently observed large trees in the forest, and bushes and sprouts aronnd stumps in arable land die at that time. But the reason given on account of there being less sap, might be carried farther, and say the winter months, when there was neither sap in the body nor root of the tree apparently, would be the most effectual time to kill them. And as to the moon, ten years experience in farming, from the result of the most inquisitive inquiry, upon what is called the best signs in the moon for sowing, planting, &c. and having made experiments in every instance in farming, has conclusively satisfied me that the farmer has no farther use for the moon than to give him light. If there is any influence in the moon upon sowing, planting, &c. it is not uniform, for upon a certain sign in the moon some years a crop may succeed well, and upon the same sign in other years prove a failure. I will mention a circumstance which, perhaps, has crossed your observation, of two learned men, (their names do not occur to me,) one in England and the other in France, making, by agreement, at the same time, observations upon the influence of the moon on vegetation, and the result of their experiments proved differently. Upon my farm I found a great many locust, and being anxious to exterminate the most of them, I was told, for the most effectual way, to skin them in the old of the moon in August. To one thicket, at that time, I done so; but to my disappointment sprouts put up as thick as if they had been cut down in winter or spring, but they did not grow as vigorously, which I ascribed to heat, dryness, and the short time they had to grow in. I was then told to skin as soon as the bark would slip, (which is in May,) which I have since done, and where duly observed I have never had a single sprout to put up, and the trees would tumble down in a short time.

Sir, the disposition this deserves you are the judge of.

Your ob't serv't, T. G. G.

P. S. The crop of wheat in this section I do not think an average one, but better than has been for several years, though but little sown. Oats and grass very heavy. Clover, last spring's sowing, failed, owing to the drought in the spring. Corn very promising at this time. G.

On Dwelling Houses.

New-Preston, Litchfield Co. Ct. Oct. 7, 1839.

J. Buel—In your valuable paper the Cultivator, in one of its numbers last spring, I think, a writer set forth the dampness and consequent unpleasant and unhealthy nature of dwelling houses constructed in the country of stone, to be such that no wise or judicious person ought to think of building the walls of a dwelling house with that material. I think a fair and full experiment, such as myself and others have had in this vicinity, is worthy to be contrasted with the above denunciation of what I consider the best building material in very many parts of our country.

In the summer of 1831, I erected a stone dwelling house on moist land, having water running from the cellar at all times in wet seasons. I can say I think, with entire truth, that my house, in all parts and respects, is as dry as any other house, in its cupboards, closets and rooms, except one small lodging chamber, and this may not have shared in the general protection. When the wash-boards were nailed in their places, I purposed to have them completely filled with mortar; and in all places exposed to be made the gangway of rats, the mortar was well filled with flat stones. This has had but little effect in stopping mice, but I think the effect has been good in keeping off rats. My house is furred with one and a quarter inch stuff, and lathed throughout; and this, stopping the damp air from passing into my rooms and behind the walls, makes my house dry and pleasant. In all changes and sudden thaws, my house is as pleasant as any constructed with wood in the country. Eight years residence in my house has never led me to regret that I built of stone; and wherever the great materials are near at hand, stone, sand and lime, I would say, use them in preference to brick or wood; but be careful in all your buildings to stop the damp air from passing from the cellar behind the walls, or in any other way into the rooms. Framed houses have sills and timbers on which the floors and wash-boards are mostly placed, entirely excluding the cellar air, which may be the great reason why they are more dry than stone or brick. My house is 61 feet by 30–31 feet, the kitchen and wash-room having a recess in front of 6 feet. By close calculation, my house cost $150 more than wood, being two stories high and ten feet between joints. I transported my pine lumber forty miles. Respectfully yours,

SAMUEL AVERILL.

Berkshire Hogs.

Black Locust Grove, Mo. Sept. 21, 1839.

Hon. J. Buel—Dear Sir—Will you request your neighbor, C. N. Bement, to inform us, what is the general or common color of full bred Berkshire pigs. We have some in this country, brought from Ohio, which are black, claiming to be full blood; some, said to come from New-York, which are white, said to be full blood; the owner of which says there are no genuine Berkshires that are black. Both kinds that are here are good hogs; the white ones have heavy ears, the black ones small ears. Now, our desire is not to be imposed on as to the blood; if we have the genuine Berkshire, we wish to know it; if not, we want them. An answer is requested. Respectfully yours,

A. H. F. PAYNE.

In compliance with the above request, I have extracted from the "Complete Grazier," describing them as they were exhibited in 1807, by the late Sir William Curtis, at the cattle show of Lord Somerville, where they attracted universal admiration.

"They were of the Berkshire breed; the specific characters of which are a reddish color, with brown or black spots; sides very broad; body thick, close, and well formed; short legs; the head well placed, and the ears large, and generally standing forward, sometimes pendant over their eyes. Another distinctive mark of this breed is, that the best are without bristles; their hair is long and curly; and from the rough appearance, seems to indicate coarse skin and flesh; but, in fact, both are fine, and the bacon is of very superior quality. The hogs arrive at a very large size, and have been reared even to the weight of 113 stone, (904lbs.)"

From "Loudon's Encyclopædia of Agriculture," published in 1831, I extract the following description of the Berkshire pigs at *that time.*

"The Berkshire breed is distinguished by being in general, of a tawney, white or reddish color; spotted with black; large ears, hanging over the eyes; thick, close, and well made in the body; legs short; small in the bone; having a disposition to fatten quickly; and when well fed, the flesh is fine. Berkshire has long been famous for its breed of swine, which, as it now stands, is in the third class, in point of size, excellent in all respects, but particularly as a cross for heavy, slow-feeding sorts. It has extended itself from the district from which it takes its name over most parts of the island; is the sort mostly fattened at the distilleries; feeds to a great weight; is good for either pork or bacon; and is supposed by many as the most hardy, both in respect to their nature and the food on which they are fed."

The Berkshire pigs, imported by S. Hawes, Esq. in 1832, of which I came in possession in 1835, differ, in some respects, from either of the foregoing descriptions; and they are the ones from which have originated pretty much all the Berkshires now generally introduced in almost every section of this continent. The color is invariably black with white spots on the body; feet sometimes tipt with white; and some white on the face and nose. Short and smooth coats; fine skinned; some of them have smaller heads and ears than those described above; long, round and deep in the body; short in the leg; broad on the hips and loin; large and full in hind quarters; hams well let down; and light in the bone and offal. The sows are good breeders and nurses, producing two litters in the year, from eight to fifteen at a litter.

I never have seen one of the full bred Berkshires entirely black; in fact, I should look with a very suspicious eye on one without some white, let it come from where it would.

They may, with propriety, be termed "graziers," for they will feed and do well on grass alone. After the pigs are taken from the sows in the spring, I cause rings to be put in their noses, and turn them out to pasture, without any other food, until they litter again in the fall. This is not only a great saving of expense, but saves considerable time, which can be more profitably employed in the field.

I have now an imported Berkshire boar, from a different strain, with more bone and size, which I intend breeding to this fall, and hope to have a good supply of pigs for sale in the coming spring. He is lighter colored than the former importations; was one year old last June, and measures 5 feet and 6 inches from his nose to the root of his tail, and around his girth 4 feet and 4 inches, in ordinary condition. Very small head and ears; legs short and of sufficient size to sustain great weight when fattened. Yours respectfully,

CALEB N. BEMENT.

Three Hills Farm, Nov. 12th, 1839.

A Hint to the Publisher and Friends of the Cultivator.

Lake C. H. Ia. Oct. 20th, 1839.

Hon. J. Buel—Dear Sir—I have adopted a plan with the Prospectus of the seventh volume, that promises much usefulness. You offer agents from 10 to 25 per cent upon subscriptions obtained. All wrong—wrong to offer a greater premium for a large number than a small one. One may exert himself more in one place to obtain ten subscribers than another would in another place to obtain a hundred. But more than all, it is wrong to offer any per cent. What? am I to believe that the spirit of agricultural improvement is so low, that the friends of such a paper as the Cultivator are so much more beset with the love of money than the good cause that we are engaged in, that they must be paid for asking their neighbors to read and be enlightened? I will not believe it. And as for your "per cent," for one, I will have none of it. But I tell you what I will do, since you can afford to pay it, I will take it, and PAY THE POSTAGE ON THE VOLUME WITH IT. Thus, I endorsed upon the prospectus, as follows:

"TAKE NOTICE—As I charge NO COMMISSION, one dollar in advance will pay the subscription, *and the postage*, upon this volume of the Cultivator."

Are there not hundreds who are as willing as I am to help the good cause along, and "charge no commission?" I assume to answer in the affirmative. The "hint," then, that I would make to you is, that you should say to every person in whose hands a prospectus may come, whether they obtain a greater or less number of subscribers; to take enough out to pay the postage. And the "hint" that I wish to give the friends of the Cultivator is, to practice upon my "no commission" principle. Thousands will take the paper upon these terms, that would not take it and pay the postage, extra. Try it, I pray you; I am sure I cannot be mistaken. To every gratuitous agent who obtains such a number of subscribers that you can afford him a gratuitous paper, no doubt he will accept it with pleasure. But the grand object must not be lost sight of by the conductor and friends of the paper, that is, to increase the circulation as far as possible, and no better plan than the one I have adopted, I believe can be adopted.

I remain, as usual, your friend, &c.

SOLON ROBINSON.

Advertising.

Judge Warner has my thanks for his kindness in giving publicity to the preventive he has so successfully used for bloody murrain; I have used ashes for horses and hogs all my life, but not for cattle; I am now trying it, and will, God willing, try it effectually.

You have deprived me of an argument that I have hitherto used in favor of your valuable paper, in order to get subscribers; and that was, that it was indeed and in truth what it purported to be, not an advertising sheet, but devoted to the cultivation of the mind and soil. Now, sir, we wish to bind our numbers as a book of future reference, and we have no wish to bind a bundle of advertisements; besides, the advertisement of "A Splendid Country Seat in the Highlands, on the Hudson River," and such like, must be of little importance to a vast majority of your readers. I would not, sir, by any means be considered as marking out the course of the Cultivator or its able editor; but instead of one page of each number being nearly filled with advertisements, would it not be better for those wishing it to pay for a quarterly extra sheet, to be styled the "Cultivator Advertiser?" Indeed, it seems to me they might very well afford it, seeing that your valuable paper is read in nearly all the States and Territories of the Union, and in the British Provinces of North America.

The above is, sir, submitted to the consideration of your superior judgment, and hope it will be received in the same spirit that it is written, and from the sole motive of benefitting mankind in general, and your readers in particular, by the perusal of "many valuable essays from other periodicals," instead of such advertisements as the above. Yours most respectfully,

AUGUSTUS H. F. PAYNE.

Black Locust Grove, Sept. 21, 1839.

We would inform our correspondent, that in order to remedy the evil complained of above, in our next volume we intend to dispense with advertisements, and probably print a semi-annual or quarterly advertising sheet, which may be done with as our subscribers think proper, providing sufficient encouragement is given to warrant us in so doing.—*Cond.*

On Hay Making.

Clinton College, 17th Sept. 1839.

Hon. J. Buel—Dear Sir—In the August number of the inestimable Cultivator for the present year, p. 121, I see a revolving horserake recommended by Mr. Dexter. Of the advantages of this rake I am not informed, such improvements in the implements of husbandry not having yet reached this western country; but if my view be correct, of the best and most economical mode of making hay, we have, perhaps, no need of a rake of any kind. I therefore write for information, and am willing at the same time to benefit others as far as I can. I shall detail briefly my plan, with the hope that if any of your numerous readers have a better, they will favor me and the public with theirs, through the Cultivator. I have travelled some, and read a little, for agricultural information, and have practised, as circumstances would allow, upon those plans which my opportunities have taught me are the best. Hay making has been, with me, a subject of close attention: and my plan, as taught me in Kentucky and elsewhere, and confirmed by experience, is this: As fast as the grass is cut, (when there is no dew or moisture on it,) as many hands follow the scythes, as can keep close up to the scythes, in *shocking* or cocking *the hay in its perfectly green state.* If the sun does not shine on or wilt the hay at all, so much the better, and for that reason it must be shocked as fast as it is cut. The shocks are made about six feet high and six feet wide at the base, and tapering like a cone to the top, and then dragged down with the fork to make them turn rain. All this can be speedily done with the hay fork, one hand being able to gather and shock three acres, or six tons, per day. The rake spoken of may do better than this, but I doubt it, and should like for Mr. Dexter, or some one else, to specify the amount a hand can rake and shock per day with that instrument.

As you remark, I never spread the hay, but proceed to shock after the scythe as fast as it is cut, by following along the swath, and with a fork, *rolling* the hay till I get as much as I can raise on the fork, when I pitch it on the shock. Thus I continue to carry as many swaths to a row of shocks as will complete them. I always roll *towards* the shocks to save walking with the hay, which is laborious. This plan of collecting the hay will be more approved, when you understand *an improvement I have made in the mode of cutting hay.* I do not mow with the scythe, as is common, but I *cradle the hay,* (as will be explained,) which throws all the grass into swaths double as large as those made in the usual way, and hence the hay is already collected into sorts of winrows by the cradle, so that the rake is not needed.

For cutting hay, make a cradle with two fingers only. Let the one nearest the scythe be 7 inches shorter than the blade, and so arranged as to let its point nearly touch the blade; let the second finger be 7 inches shorter than the former, and arranged so that its point may come in one inch of touching the first finger, and you are now ready for business. In cradling, *do not mow, but give the usual stroke of cradling grain,* only take care to set your cradle in no further than you can carry out with ease. In cradling grain close to the ground, you have to squat a little in making the stroke, proceed the same way in grass, and you shave it to the ground.

I know that the farmers of the old states, who have made hay all their lives, will laugh at this plan, and particularly at the idea of a Tennessean proposing to *show them* something new in cutting hay. They will argue, that a cradle will be too heavy, and that it will tangle, and cannot work in dense hay. Let them try it. The denser the grass the less you must cut at a stroke, and your cradle will go easily through, thick and thin. But the great advantages of *the improvement* remain to be told. They are no less than three. 1st. In this way you cut twice as much in a swath as in the common way of mowing, and then the grass is *all* collected into a winrow as you proceed, and not left scattered as the scythe would do it. Thus the labor of raking is saved, and less of the hay is left on the ground at the end of the process. Besides, the cradle cuts it perfectly clean under the swath, which few hands will do with the mowing scythe.

2d. The process is less laborious than mowing. No man who ever cradled hay would mow, if you gave him his choice as to the mode of cutting.

3d. *A hand can cut double* as much in the day as he can do with the mowing scythe. If a hand can mow one acre per day, he will cradle two acres of the same grass with less labor.

I have tried this plan but one season, having cradled about fifty acres of timothy alone, and of clover and timothy mixed. The cradle does so well in these kinds of grass, that I expect to have no use for mowing scythes hereafter in making hay, unless the plan should fail in herdsgrass or redtop. I have not tried it in that grass, as I have grazed my herdsgrass this year, instead of cutting it for hay. I wish my brother farmers to try this plan effectually, with a strong cradle blade, and let me hear from them next summer, in the Cultivator.

But to return to the process of curing hay. Having shocked as before described, (I mean timothy or herdsgrass,) I let it remain for six days, when I run my hand to the centre of each shock; if I find them still cool, I do not disturb them, but if any are warm, I put the left hand on the top of the shock, while the right is thrust to the centre, and turn the upper half down to the ground, so carefully as not to disturb its form, and leave it inverted. In an hour or two, the whole is cool, and I then take hold in the same manner and place it back on the shock as it was before. Not more than one shock in twenty will ever get warm at all, (most of them curing fine and green without heating,) and none will need turning down more than once. In this way, your hay has three signal advantages over that made by spreading and curing in the sun. 1st. It costs not more than half the labor of spreading and shocking repeatedly till dry. 2d. You run no risk of getting any injured or lost by rain. 3d. You get more hay both by weight and measure, and the quality of it is far better than can be made in the sunshine and open air, both of which dissipate much of the nutritious virtue of the hay. Yes, much more of the virtue of most of the products of the farm is lost by exposure to the air, than is generally believed. You have to be particular to cut and shock when there is no dew or rain on the grass, (for if wet it will heat)—examine it once in six days—and be sure to let it be well cured before you stack it, and you cannot fail to make the best of hay, *in any season,* without injury or loss.

When I make clover hay, I follow the foregoing plan in all respects, till it is shocked. Then I haul and stack it perfectly green, in large stacks, taking care to *salt* and *tramp it well* while stacking. I use about as much salt as the cattle would require while eating the hay, say 50 lbs to a stack 16 feet high and 14 feet at the base. In five or six days the stack becomes hot and smokes profusely, but in two or three weeks it will have "gone through the sweat," and be found perfectly dry and sweet. The less wilted before stacked, the less it heats and the better the hay it makes. By this process the hay is of a dark green color, and all kinds of stock will eat it greedily and thrive upon it. It shrinks but little in curing and looses no leaves, and is in all respects better for cattle, horses or sheep, than clover cured in the open air.

Respectfully,

FRANCIS H. GORDON.

P. S. In your March number, page 13, Mr. Brewer recommends Robert Rittenhouse & Co.'s Patent Clover machine. From his letter, I admire Mr. B. as a farmer, and should be glad to learn from him or yourself,

1st. What amount of seed the machine will clean per day?

2d. Is it worked by horse or human power?

3d. How many hands are required to attend it?

4th. Does it get all the seed out of the chaff?

5th. What is its weight? how large or what space does it occupy?

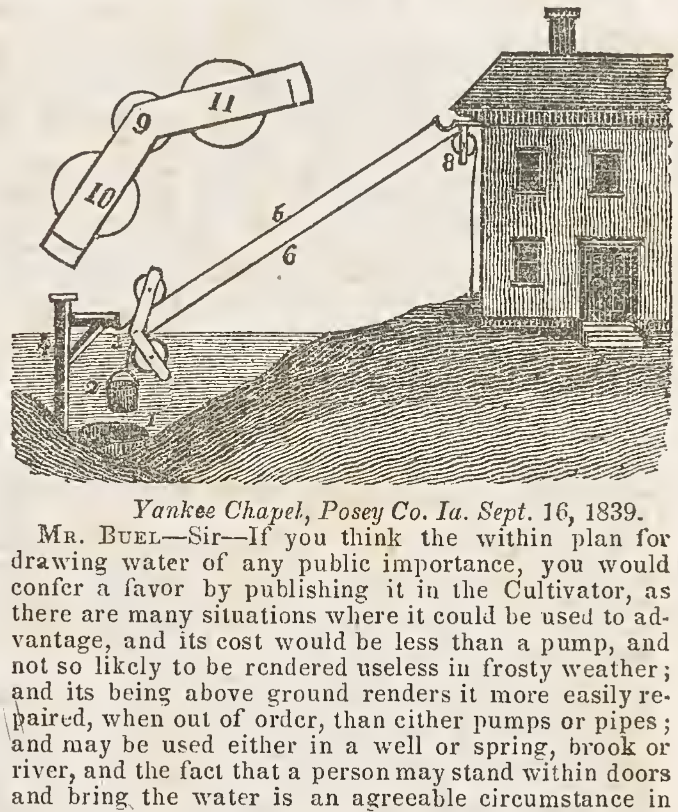
6th. Can a common farmer keep it in order, or does it require a workman?

7th. Can one be had in Philadelphia, Baltimore or New-York city, and to whom should I apply.

Last year I made one hundred bushels of clover seed, but the process of tramping with horses is so tedious and so disagreeable, that I feel discouraged, and should be pleased to learn a better plan; I therefore shall be happy to learn the particulars of this machine.

Plan for Drawing Water.

[Fig. No. 45.]



Yankee Chapel, Posey Co. Ia. Sept. 16, 1839.

Mr. Buel—Sir—If you think the within plan for drawing water of any public importance, you would confer a favor by publishing it in the Cultivator, as there are many situations where it could be used to advantage, and its cost would be less than a pump, and not so likely to be rendered useless in frosty weather; and its being above ground renders it more easily repaired, when out of order, than either pumps or pipes; and may be used either in a well or spring, brook or river, and the fact that a person may stand within doors and bring the water is an agreeable circumstance in stormy weather. The above plan was suggested to me by an intelligent Frenchman, who informed me that he saw it in use in Naples. The figure 1 denotes the well or water; 2 the bucket; 3 the sheth block, which should be of cast iron, with 3 sheths or wheels in it; those at the ends, marked 10 and 11, should be 2½ or 3 inches diameter; the one in the centre, marked 9, about 2 inches diameter; 4 is a post, which should be very firm, and an arm in it, to which a strong wire is made fast, and so arranged as to be tightened or strained by a screw in the arm of the post; the wire, marked 5, is made fast at the other end immediately over the spot where the water is to be brought; No. 6 is a cord made fast at one end to the bucket, passed through the block and over the wheel No. 10, and then over a wheel in a block No. 8, which block is made fast near the point where the bucket is to stop; then the end or fall of the cord may be put to a windlass or drawn by hand; the wheel No. 11 runs on top of the wire, and that marked 9 runs under the wire; there should be a small notch directly over the spot where the bucket is to stop, into which the wheel No. 11 drops, and renders it stationary, while the bucket descends; and a spring or lever is brought to act on the wheel No. 11, by pulling a cord for the purpose of raising it out of the notch, when it is desired to have the bucket return to the well or water, which it will immediately do the moment the wheel No. 11 is lifted out of the notch, when it will continue to descend until it comes in contact with a projection at the end of the wire, over the well, when it becomes stationary, and the cord gently passes over the wheel No. 10, and lets the bucket fill; then upon drawing the cord until the bucket comes up and in contact with the lower end of the block, all begins to ascend the wire to the desired spot; the block should be bent as shown by figure 7, as the wheels will work much better than if it was straight; and the surface of the wheels should be fluted or hollow, so as to cause them to run more truly on the wire, and under the wire and cord.

Also I send you a sample of grass, from the meadow of Mr. John B. Wallace of this place, which I think should be cultivated more generally, as it is a very hardy grass, and is nearly all leaf, the stem, on which the seed is formed, being so short as seldom to be cut by the scythe when mowing, and which produces more hay, and of a better quality, than any I ever saw. This grass is indigenous to this country; its merits, however, have not been fairly tested, though so far appearances are favorable. The fact of its having no straw I consider to be of importance, as the hay would be much finer, and I think more nutritious than where a large portion of the mass is stem or straw. Mr. W. is only engaged in experimenting on it as yet, though I shall feel much disappointed if it does not do better than any other grass now cultivated for hay. This spire which I send you I took no pains in selecting, though it measured 4 feet 8 inches. Yours, &c.

MICHAEL W. ROWE.

The Mad Itch.

Washington Co. Ia. October 21st, 1839.

Dear Sir—There is a complaint raging to some extent among the cattle in this country, called the "Mad Itch," which appears to be incurable, and if you or any of your numerous subscribers could give information how to cure it, you would confer a great benefit to the public.

Not having seen any account of it in the Cultivator, I will describe it as near as I can. It takes the cattle with an itching on the nose or around the horns; they then commence rubbing and throwing their heads and frothing at the mouth, and in about twenty-four hours they are dead. If you or any of your subscribers know any cure or preventive, I want it published in the Cultivator. HERVEY DEMY.

To Cure the Fowls in Cattle—Rohan Potatoes.

Priceville, Wayne co. Pa.

Take corrosive sublimate, pound and dissolve it in spirits, water will answer, pare and cleanse the part well between the claws, or where affected, apply the mixture one or twice is a certain cure; I have never known it fail in twenty years's experience.

From one potato which Mr. Rains purchased of you for me last fall, I raised four bushels; they were planted four feet apart each way, one eye in a hill, thirty-two hills—not much manure was used. I am now selling them, the large ones, for twenty-five cents each. Profit enough to pay my subscription for the Cultivator since its commencement. JACOB W. WELSH,

Manchester.

Double and Single Flowers.

Manlius, Oct. 25th, 1839.

"We invite, on all occasions, liberal criticism. It is the collision of flint and steel that elicits light."—*Con. Cul.*

J. Buel—Dear Sir—You will observe, at page 123 of the present vol. of the Cultivator, in answer to questions propounded by Phineas Pratt, speaking of deteriorating plants, flowers and seeds, "Hence florists destroy *single* and *imperfect* flowers, lest they should fecundate and *destroy* the seed of double flowers." I believe, sir, botanists never select double flowers for analysis *because they* are imperfect. Their stamins become changed to petals, and frequently the pistils too by cultivation; their natural character is often destroyed: it is, therefore, difficult to determine by analyzing a double flower how many stamins or pistils belong to it in its natural state; consequently no true class and order can be given, although the beauty of flowers may be increased by cultivation. Yet their relative beauty, as subservient to scientific illustration, is certainly destroyed by the labor of the florist. Flowers in their natural state, unassisted by cultivation, are usually single, and are considered perfect by botanists. They should not, therefore, be *destroyed*, or set down as *imperfect*, *because* they are single. Yours, &c. respectfully.

FARMER C.

The Tree Corn.

Manlius, Oct. 25th, 1839.

J. Buel—Sir—Having of late, in different prints, observed many harsh epithets used against Grant Thorburn and his "*tree hill corn*," I take the liberty of stating a few facts in relation thereto. Last spring a friend of mine gave me 30 grains of the celebrated tree hill corn purchased at Thorburn's at 25 cents per ear. I gave away 3 grains and 2 did not vegetate; which left me 25 grains to grow. These I planted on the 13th of May, in my garden; they grew to the height of from 8 to 10 feet each. It was hoed three times. On the 2d of Oct. I harvested, of sound corn, 62 ears, with some 10 and some 12 rows each; 2 ears were 10 inches in length; 5 others of 9 inches; 12 others of 8 inches; and the remainder were from 5 to 7 inches in length. Perhaps I should have come at the product more exactly had I shelled and weighed it; but as it is, enough is set forth to prove it a great yield, and the shrewd old Scott should not be ycleped the worst of beings by the good people of this country, even if he has sold them corn at 25 cents the ear. "Look before you leap, and never cry for broken bones."

FARMER C.

P. S. From 5 Rohans, of middle size, I raised over three bushels; they did not get quite ripe; they were planted 22d of May, and dug 3d of Oct.

On Propagating the Peach.

Kipton, (Vt.) Sept. 30, 1839.

Hon. Jesse Buel—Dear Sir—In the Cultivator for Oct. 1838, page 133, I observe the following directions are given for raising peach trees: "The stones may be buried in the ground during the winter, and those which are not cracked by the frost may be broken before they are planted."

I pursued this method for several years, and not having been very successful, I began to suspect that, instead of aiding nature in her simple operations, by the application of frost, I had counteracted her efforts, and concluded to try the application of heat and moisture, instead of frost. Accordingly, I took a quantity of peach, cherry and plum stones, with a number of walnuts and butternuts, or, in the language of the south and west, hickory nuts, and white walnuts, wrapped them in a cloth, that I might more conveniently take them out of the ground in the spring, and buried them in a loose muck under a fence, where they were covered with a snow-drift during the winter. When I took them out in the spring the sprouts had perforated the cloth in all directions. When I opened the cloth I found the stones, as well as the walnuts and butternuts, all opened, and the young plants disengaged from them, which I placed in the ground, and they all grew. This was about forty years ago, since which I have always pursued the same method, omitting the cloth; and have generally found the stones opened in the spring; always, I have believed, when they were put in the ground before they had become dry, and were kept sufficiently warm during the winter; and those which were not opened in the spring being planted generally came up.

That either frost or the hammer is necessary to open peach stones and cause them to vegetate, is certainly an error; but since frost will not prevent, but only retard vegetation in this case, the correction of the error may not be of sufficient importance to find a place in the Cultivator; of this you will judge.

Since I have a small space left, I will fill it with a few remarks in relation to raising potatoes from the seed. I believe that the seeds are generally taken from the balls in the fall, dried and planted in the spring; but I have found that if the balls are buried in the cellar when they are taken from the vines, and the seeds planted in the spring, they will come up sooner, and the potatoes will be larger in the fall.

DANIEL CHIPMAN.

Query.

Near Rockingham, 22d Sept. 1839.

J. Buel,—Sir,—A few days ago six of my cattle were taken down with a disease caused by eating too much green corn, having broken through a very bad sod fence. Yesterday three more were taken in the same way. I could find no remedy for such a disease in any of the cattle books, and was totally at a loss what to do. An ox of a neighhor was taken down at the same time; he gave him about a half a gallon of soft soap and lard.—His ox died. Fortunately I had no soap, and could give no such dose. Some of mine I bled in the mouth, for others I did nothing. They are all getting better but one, which I shall probably lose.

The object of this letter is to learn from you, or some of your correspondents, what remedy should be applied in such a case. I do not mean a quack remedy, soft soap for instance, but some remedy based on medical principles. I should have added, that my cattle were taken with a violent purging, attended with extreme debility, and a dullness amounting in some to utter insensibility. Yours, truly, JAS. GRANT.

Doing Good to Others.

Chatham, 2d Oct. 1839.

Jesse Buel, Esq.—Dear Sir—"Recollect you have it in your power to do a great deal of good!" This was your last and benevolent expression on parting from you a few weeks since.

It has been my rule, occasionally, when I observed worthy and energetic overseers, to subscribe for some agricultural work and send them by way of encouragement, and it has not only been the means of exciting their energies still further, but inclines them to habits of reading, and its results are gratifying to me, and beneficial to them. So also, I have subscribed for some young and industrious farmers, without letting them know from whence it came, and have invariably found it to result in good, not only to them but to a circle immediately around them; in a few years after beets and ruta baga is a part of their crops, liming and manuring indispensable; and thus your Cultivator becomes the necessary adjunct, and I find it circulating in neighborhoods where otherwise it would not have found its way probably for years. And thus I try to fulfil your excellent admonition, although in a small way, doing some good to you and the cause of agriculture, (to which we are both enthusiastically devoted,) and more, perhaps, to others. How many are there, among the great and the wealthy, that might do likewise; be the means of disseminating the true science of agriculture, and of advancing the noble cause of agricultural education throughout our land, and never feel the loss of a few paltry dollars. N. P. C.

A skillful agriculture will constitute one of the mightiest bulwarks of which civil liberty can boast.

EXTRACTS.

The Life of the Husbandman.

"I am a true laborer. I can earn that I eat, get what I wear, owe no man hate, envy no man's happiness; glad of other men's good, content with my farm, and the greatest of my pride is to see my ewes graze and my lambs suck."—Shakspeare.

We have come to the conclusion, that nature's truest nobleman is the man who earns his bread by the sweat of his face, upon his own bought and paid for plantation. An independent Farmer may stand upon his house-top, and say to himself as Selkirk did:

"I am monarch of all I survey
My right there is none to dispute;
From the centre all round to the sea,
I am lord of the fowl and the brute."

He is truly a monarch—with a landed title more secure than that of feudal Lord or Baron,—more easily protected and preserved, not by deeds of valor, and through the shedding of blood, but by the lawful labor of the hands. His house is his castle, his acres are his dominions. His gardens are his parks, his grass plats his lawns, and his forests his groves. His cattle, sheep and poultry are subjects, and he becomes, at pleasure, either the executioner or the multiplier of such subjects. Tell us if the King upon his throne has more power worth possessing. His happiness we know is less, as he increases his toils, cares and sorrows in proportion as the cultivator of the soil diminishes his.

In the spring time he sows, in the autumn he reaps. Providence has assured him that spring time and harvest shall not fail, and he has the assurance of the Giver of every good and perfect gift, that as he sows so shall he reap. His grounds are watered in the season of drought, with the rains and dews of Heaven, and in the damp season the sun shines to cheer, invigorate, and give promise to his labors. The severer tasks of the summer are succeeded by the lighter labors of the winter. As we have said in the words of Will Shakspeare, he "earns that he eats, and gets what he wears," and his philosophy is that of the shepherd who said that "good pastures make fat sheep." He may say truly, and with an honest pride—

"I eat my own lamb,
My chickens and ham,
I shear my own fleece and I wear it."

What could a man want more; and how can a farmer, capable of enjoying life, possessed of his farm house, his farm, and his necessary implements of husbandry, ever sigh for a residence within the enclosures of a city, —choosing bricks and mortar, for the elbow room of a spacious farm house, the smoke and dust of the town for the village, the three or four story brick house for the granary or the haycock,—the purest air of heaven for the atmosphere of a thousand smokey houses, and ten thousand unwholesome breaths? How could a farmer make such a choice as this? We would pause for a reply, did we not know that the only answer which could be devised, after a long study, would be the unsatisfactory one, that something better was anticipated only,—for it would be a miracle almost, for a man to find himself happier or in better circumstances after a a change of residence from the country to the city.—No,—no. The true Elysium,—the real Paradise on earth, is the country,—the green, fruitful, beautiful country. The city for the taskmaster and his hard-working servant; but the country for the man who wishes for health and leisure,—contentment and a long life.

The ancient Romans, venerated the plough, and in the earliest, purest time of the republic, the greatest praise which could be given to an illustrious character, was a judicious and industrious husbandman.—*Portland Advertiser.*

The American Farmer.

The following beautiful description of our most worthy and happy class of citizens, is from the address of the Hon. Mr. Rowan of Kentucky, to the citizens of Louisville. If any one would inquire why farmers are more worthy than any other class, this description will answer the question. They follow that profession which is most essential to the public good, and which is the foundation and support of all other useful employments; and the situation of farmers leads them to a higher state of moral worth than any other class will attain—*Yankee Farmer.*

"Who is there among us that beholds the condition of our farmers, and does not exult in the consciousness that he is an American citizen, and pant to superadd the character of a farmer? The house of the farmer is the abode of the virtuous. It is a school in which lessons of practical wisdom are taught. It is a temple in which the precepts of our holy religion are inculcated. It is the castle of sovereignty, for it is owned by its occupant and he is a freeman. It is the residence of peace, order, harmony, and happiness. Patriotism and piety unite in consecrating the place, and in suffusing every countenance with their unction. Indeed, what condition in life is so likely to produce that patriotism which will stand the country in stead upon emergencies, or that piety which will afford solace in extremity, as that of the farmer? He occupies a constant, intimate, and sensible relationship with Heaven. His mind is subdued with a love of order, by constantly beholding that which prevails around him. The regular successions of the seasons, of day and night, and of seed-time and harvest, admonish him to the observance of regularity and order in all his conduct. He perceives that the sun and moon perform their circuits without loitering on the way; and learns from them that industry is required at his hands. He looks to Heaven through its rains and dews, for the reward of his labors in the abundance of his crops.—He makes the sacred volume of revelation the man of his council, and the source of his consolation. He unites with his wife and children in tones of supplication and strains of praise around the family altar on the morning and evening of each day. He acknowledges no sovereign but Heaven and the people; he bows with appropriate reverence to the will of each, and exults in the freedom of his own, for his homage is a free-will offering claimed at his hand by the convictions of his reason. His affections are conducted by his judgment and not by his fears, in his devotions. Matron chastity, and infantile innocence sweeten and religion hallows the atmosphere of his home, and render it irresistibly attractive. He loves his country because the farm and the domicil of which he is the proprietor, and with which his affections are identified, are a part of that country. His patriotism is an essential part of his conscious identity. Connected by his affections with the soil, and by his piety with heaven, it partakes of the stability of the former, and the purity of the latter. It inspires him with holy enthusiasm in the cause of his country, when its honor or its safety is concerned. It is electric, and strikes every contiguous bosom till it pervades the community."

How to Preserve Tomatoes for Winter.

Among other improvements in Horticulture, I have been gratified to observe the increased cultivation of the tomato. Believing this to be a most healthy vegetable, I send you an account of the manner in which, universally in Asia Minor, they are preserved for use during the winter.

Cut the tomatoes in two when quite ripe, and sprinkle considerable fine salt on them over night. Next day pass them through a cullender, moistening them with a little water; set the part thus strained through to dry in the sun, in shallow dishes, in depth half an inch or an inch; and when hardened to something more than the consistence of a jelly, put it away in covered jars, without any other preparation, for daily use. Should it show any signs of injuring, add more salt, and expose the jar again to the sun. This, it is presumed, will seldom be necessary—a specimen of what was prepared for my family more than twenty months ago, is still in a fine state of preservation.

A table spoonful of this tomato jelly is enough to impart a relish to a dish of *pilaf*, that is, rice cooked with meat or butter, or soup, for a large family.

Rohan Potatoes.

The last of May, 1838, I received from my friend, the Hon. J. Buel, of Albany, one Rohan potato, which yielded 50 lbs. The last of April, 1839, I planted 48 lbs. of seed and from it on the last of September last, I harvested 4,204 lbs. which measured 74 bushels—many of the tubers weighed over 3 lbs. each—and 20 of the largest filled a bushel basket.

Elmira, Oct. 8, 1839. HERVEY LUCE.

Breeding Swine.

From the Franklin Farmer.

We feel very much indebted to the writer for the following excellent communication on a subject of the greatest importance. The rearing of swine is a department of rural economy in which there is room for the greatest improvement, and we think our Kentucky breeders will find much useful information and many valuable hints in the communication below.

Buffalo, N. Y. August 31st, 1839.

To the Editor of the Franklin Farmer;

Sir—Agreeable to the intimations in my last, I now come to the rules adopted by the most successful breeders of Berkshires in this vicinity: your readers will excuse my particularity in stating them, for the reasons that the article of pork, as before asserted, is the most important item of western agricultural production, and that I am writing to those who are not *above* their business, but who take the same pride and pleasure in raising a fine race of hogs, as they would in that of blooded horses or Durham cattle.

A boar should never be permitted to be used till seven months old at least, and it would be much better that he were allowed to run till nine months. But if commencing at seven months, he should cover sparingly, say not more than fifteen or twenty sows till a year old, and these as distant apart as possible—one or two only in a single week. From this time till he has attained pretty full vigor, which I should place at about eighteen months age, he may be used a little more freely. His spring seasons might then vary from twenty-five to thirty sows, and his fall nearly double this number. In the meanwhile he should be kept with care. A strong door may open from his pen into another, to which the sow is introduced, the boar is then let in and allowed one coitus only, immediately after which he must be turned back, and the sow taken away. It has generally been noted that one covering produces a greater number and stronger offspring than two or three, and that an *ad libitum* service, is alike pernicious to all parties.

The best food for the boar during the season, is boiled or soaked corn, with plenty of pure fresh water, and for a variety some swill from the house with meal in it (oat is the best) and a raw or boiled vegetable root or two; and as an antidote of disease, and to give tone to the appetite, and assist digestion, a table spoonful or so of sulphur is occasionally put in his food. Salt is also placed where he can get at it when he pleases, and charcoal or small chunks of rotten wood, together with a handful of crushed bones, if convenient, is thrown. He must be kept up alone in his stye under close cover with a plank floor and plenty of dry litter, the sleeping apartment communicating with a good yard to exercise and root and wallow in, and a strong post placed upright near the centre for him to rub against.

During the interim between the spring and fall seasons, it would be greatly conducive to the health, vigor and longevity of the boar, if he could have a run in a cool grass pasture, with clear sweet water passing throughout, and take lighter food than when in service, but yet sufficiently nutritious to keep him in fair store order. A good animal thus treated, may last ten to twelve years and get excellent stock first to last. But great care must be taken that he be not *overworked;* this is deemed very essential. It is the great fault of us Americans, that when we have obtained a male that has any way distinguished itself, instead of husbanding its resources, we use it too much, and this is one great reason why the stock of such animals so often disappoints the public. I understand that particular English breeders, limit their best horses and bulls to about thirty females, and often as low as twenty or five and twenty. What their usage is for boars I do not know, but I suspect that it would be less than here allowed. It will be admitted however that individual males, may serve well a greater number than limited above, but my principle is, not to work them up to their full capacity; if error must be committed, it is better that it be on the safe side.

Unless a sow were very coarse, and the object was to fine her, I would not allow her to breed till eighteen months old, and if something extra was desired, she ought not to come in under two years. There is then no check in growth, and the first litter is usually as good as any subsequent one. She ought to be taken up and occupy a place alone, either in a pasture or a pen similar to that described for the boar, one month previous to farrowing, her condition kept good, and strictly watched when expected to bring forth. As soon as dropped, see that the pigs are cleaned and take the teat, and the dam rid of the placenta and that carried off and buried. The watching should continue a day or two longer, till the pigs get a little strong and lively, as the sows of this breed are so heavy as to endanger their being lain or trod upon and killed. One pig more saved than leaving the sow to herself, amply repays all this extra attention. Although objections are made to giving food immediately after farrowing, I can see no reason in them; the poor animal is faint and dry, and requires nourishment, and my rule is to feed it swill in a moderate quantity a little more than blood warm as soon as it will get up and eat it. This is gradually thickened the next day, and by the time the pigs are a week old, the dam is allowed to eat all it will without cloying. A mixture of oat and pea or Indian meal, of one part of either the latter to three parts of the former, is highly recommended for nursing, together with an equal quantity of steamed vegetables. As soon as the pigs will eat, a small open door should be placed in the pen under which they could run and be separate from the sows, a trough set in, and milk, with a light mixture of oat meal poured out for them. This greatly relieves the sow, and adds much to the growth of the pigs, they wean then, without scouring, losing condition in the least, or being checked in their growth. It is generally thought that pigs do as well to be weaned at six weeks old, as later, as the little milk each then gets, is obtained by more or less quarrelling, and adds a distaste to their other food, besides it is a great consideration to get them off the sow as soon as possible. Eight or ten great pigs tugging at her breast for two or three months is hard to be borne, and frequently very pernicious to her teats. In weaning, all but one should be taken off, put the dam on short allowance, and in two days take the remaining pig away, allowing it at first, to draw the breast twice a day, and then diminish till once in two or three days during a week, then turn the sow out to grass and leave off entirely, and commence gradually putting her into condition again. The Berkshires are great milkers, and must be well attended to at weaning time, or their breasts will fill, become caked and swollen, and finally ulcerate and be the cause sometimes of the death of the sow.

Two litters are allowed per annum, and a preference for farrowing in this climate, is given to the months of April and September. Farther south later and earlier will answer. A pig when first dropped is a very tender animal, and if the weather be too cold it will perish; the dam also is likely to become ravenous and devour her offspring, or refuse to nurse it. Sows are better to be always separate, but with the owner of a large herd, this is inconvenient, and adds greatly to the expense of keeping them. One must do as well as he can in this particular, but when nearly of a size and tolerably peaceable, four may be kept together in a pen, and a dozen or so in a pasture. The breed greatly decides on this point. For instance, I could keep a hundred Chinese together without quarrelling or accidents, they are so good natured and quiet; but then again, they huddle too close, and so want as much separating as others. These being smaller and of quicker maturity than the Berkshires, the sows may come in at a year old, and when full grown, great care must be taken about overfeeding and keeping them too confined. The bellies of this stock are now nearly dragging on the ground, though they have had no other food since the forepart of May, than what they have found in a poor grass pasture. Those I have sold west, get so fat on shack by November as to be hardly able to waddle, and make the nicest of pork without further feeding. In England they are called par excellence, the "gentlemen's hog," and though their pork inclines rather too much to fat, still it is so sweet and delicate, that it is more generally preferred by those who can afford it. The crosses of these with the Berkshires are in a great repute at the Smithfield market, and I will add that what little has been thus made here, takes the preference. The hams well boiled, and eaten cold, seem absolutely to dissolve in the mouth without mastication. The average weight of my improved Chinese, may be at eighteen months old, from two hundred to two hundred and fifty pounds. Occasionally they will go older to three hundred and even four hundred pounds, but this is very rare. Though small, they have proved to the other races of hogs, what the Arabians have to horses, the foundation of all improvement.

The reader will have surmised from my observations on breeding, at least some of the causes why the Berkshires with you have not come up to the full sizes so often stated by the eastern breeder, that they arrive at, but lest he may not yet thoroughly understand the demerits of the case, in justice to both seller and purchaser, I shall proceed to briefly state them. Suppose then that we start with a pair of Berkshires from unexceptionable stock, the produce may deteriorate in size either from too great affinity in blood of the parents, breeding too young, too old, or too much. Keeping too fat, (which by the way is not often the case) too poor, or too confined—from diseases known and unknown, from runts that will occasionally be dropped, from scantiness and impropriety of food to the pig, and occasionally, over which no one has control, and that check its growth from sufferings through the inattention of the transporters to its place of destination, and finally from a general deterioration in nature. Really good animals that are every way right, are rare, very rare indeed, and when at last obtained, cannot be too highly cherished. That there may be an increased effort to produce them throughout the United States, is the ardent desire of

Your obedient servant, A. B. ALLEN.

We received the following in the same package which brought the foregoing. In reference to the hardiness of Durham cattle, since the publication of our article alluded to below, a number of breeders have furnished us with facts going to prove that this breed is equal to the native cattle in vigor and hardiness of constitution.—We should be glad to have their experience on the subject written out for publication; and it would be well if some breeder would treat the subject with reference to the physiology as well as the habits of the animals. In point of animal conformation, we never have entertained a doubt that the Durhams would be better able to endure hardships than the scrubs; and our opinions as to the superior hardiness of the latter are founded on the fear that the tenderness with which the former are usually (and very properly) treated, might tend to establish a habit in them, unfavorable to their hardiness. Let us hear from old breeders on this subject. We shall be able, we think, to settle the question for ourselves the ensuing winter.

"I was just folding up the inclosed missile to send you, when the Franklin Farmer of the 17th inst. was brought down home from the post office. I notice your just and candid remarks on hogs and cattle. You mention *deep, muddy* roads, but will gather from the contents of my last letter that I had dry ones only in prospect for the Berkshires. I was not aware that you drove in mud. The greater weight of the Berkshires in soft roads would tell against them, still I do not think the Longshanks would have much the advantage over those only a year old or so; above this age I think they would decidedly, though here with yourself, I would prefer to have a trial instead of an *opinion*—coarse bones, however, do not constitute superior strength or endurance. The same diameter of bone of a race horse, as it is more compact, finer grained, and less porous than that of the cart horse, must consequently be stronger, for instance, something like ivory compared with bone. It is said that the Berkshires possess this superiority. But there must be something aside from bone to constitute strength, and endurance—such as as ligament, muscle, &c.

"I most heartily wish that your proposition of giving premiums could be acted on at fairs. This ought to be the animal's test, the best and most meat, or the quickest and most work at the least cost—then show should never enter into consideration, only as a desirable appendage, but I fear we all have too much of it in influencing our judgments.

"As to the hardiness of Durham cattle, I will relate what I know. You can easily surmise the rigor of our climate here in the latitude of 43 degrees—but my brother's cows wintered well on Grand Island the first year he had them, on hay alone, and without shelter, other than an open shed, for he had just begun his farming and had no barn. The bull, Leonidas, belonging to my father, the two winters he was three and four years old, stood at a stack of marsh hay, and no other food except what he had out of the horse dung heap—his shelter was the lee side of the stack, he never entered a stable or slept under cover to my knowledge during this time, and never seemed to care for sleet or snow. He had a bed high and dry of the same kind of hay that he ate. He did not grow much during these winters, but came out each time in good condition. The hardiest native animals that we have, on the same fare, would not have looked as well. I consider this bull an extraordinary hardy and thrifty animal. It is not the way, however, that Durhams ought to be kept, nor do I think many would bear it; but knowing how good the progenitors of Leonidas were, and as it was never intended to sell him, and size and show, therefore, were not particularly cared for in him, the experiment of thus wintering was begun and watched as it continued, to see that he did not suffer, for the purpose of satisfying ourselves that short horns may be bred hardily. This past winter, when he had attained five years age, we were engaged in drawing out very heavy white oak timber for ship plank, and had twelve of the most powerful yoke of cattle that we could find for this business. Leonidas was put into the team, his step was as quick as the freest, and some of the oxen girthed over seven feet, not one was a match for him at a pull. His girth is about 6½ feet. He is of moderate height and very compact, and when turned out at his ease taking on flesh like a China pig. I will add, that he did the same duty and on the same fare as the other cattle, and came out in the best condition.

"Mr. Rotch, of Otsego county, where the thermometer not unfrequently falls to 30 deg. below zero, tells me that his short horns will bear *any intensity of frost.*—As the winter season approaches, a short thick under coat of hair resembling fur comes out on them, which is shed as warm weather sets in; he thinks, however, that his stock does not stand the heat quite as well as the native breeds. Still there is no doubt in my mind that these same animals taken to Kentucky would do well, with the advantage of shade trees to shelter them from the rays of the sun during the hottest part of the summer days. It is well known that animals will accommodate themselves to climate. I have a short haired New-Foundland dog, and as active an animal in summer as any I know, he sheds and grows his under coat of hairy fur as the seasons warm and cool.

"The editorial remarks on the feed and treatment of Durham cattle that appeared in No. 39, vol. 2, p. 309, of the Franklin Farmer, as a general rule are admirably just, so far as my experience goes. Does any one suppose for a minute, that a superb short horn can attain its present size and condition, turned out to the blasts of a rude Canadian winter, with a half a ton of hay and what browse it can pick up for its only sustenance during seven months, or that they can support themselves on arid lands that would starve an ass, or among rocks so thick that a peaked nose sheep can hardly get his teeth to the grass? What the breeders of imported animals contend for is, not that they will support life and keep fat on a less amount of food than another, (China hogs excepted,) but that they will give a greater combination of meat and milk, and these of a better quality, and arrive sooner at maturity. It is thus for the interest of the breeder to feed generously, and if he is not prepared with rich pastures and cool groves in summer, and comfortable stables in winter, with plenty of good hay and some meal or roots, he had better let Durhams alone, or indeed any large improved animals. For one, I have no idea of blinking the stock question, and to conclude, I will say, dont pamper and stuff, but feed well and regularly, and make your animals comfortable in all weathers, as you would like to be yourself, or high prices, with the expectation to grow and sell high again, will have been paid in vain.

"Your remarks have unexpectedly led me into so many observations upon stock, that I shall now await some abler pen before touching paper again on this subject, for I fear I may already have exhausted the patience of your readers. Be so good as to make our compliments to western importers, and say that we should be greatly obliged when subsequent herds are brought this way, that they would send the names and pedigrees of the animals with them. From the first importation of the Ohio Company, to this last by your neighbors that passed here a week ago, we have scarce got a name or pedigree with this stock. This would have been a great satisfaction to many here, for then, in hearing of their sales, produce and doings hereafter, we should know what it was. We presume that no one engaged in these importations thought of this, or we should have been obligingly favored by a full sight of all these matters. If the young bull of this lot has not *size* enough to suit Kentucky, I shall pray for the resurrection of a Mastodon from the Big Bone Lick in shape of a Short Horn for you.

A. B. ALLEN.

Notices of Improved Farm Stock—No. 2.

Before leaving Otsego, I beg to be indulged in a few remarks that may be applicable to the southern tier of counties of Western New-York. Although the winters of this region may be considered long and somewhat severe; still I think it a country admirably adapted to the growing of middle sized stock. The pastures throughout the summer are sweet, nutritious, and enduring, and springs and rivulets abound in every field. These with the fresh, grateful air among the hills, even during the hottest part of the season, makes it peculiarly favorable for stock; and all animals during the pleasant weather, thrive well. I saw here several very promising fields of ruta baga, and was told by the cultivators, that they considered it a very certain and great crop with them. When clay does not too much abound in the soil, I should think this must be so; the stone keeping the ground moist and cold, which, with a proper friability, renders it just the land for turnips. Here, then, is ample nutriment for the winter to keep stock up to the work, placing the higher altitudes nearly on a par with the lower and more ameniable regions. I could not learn that the sugar beet was cultivated at all on my route. I presume, however, some must have tried it, and I should be pleased to know how they have succeeded. Those with whom I conversed, seemed to think it would not do at all; but why, I am yet to learn. I have cultivated it with great success on a hard clay soil, and in a climate little inferior in rigor, to that of the hill country, and I must say, I think it the most valuable root crop that can possibly be raised, and am of opinion that it will yet be the *great* crop of the Northern states. To say nothing of the prospect of its value for sugar, I think it, upon the whole, the very best root we have for general stock. My pigs would last winter leave warm cooked swill, and run to raw beets thrown to them on the frozen ground. I shall however, speak of this root and its comparative value, more fully after harvesting my present crop, and in the meanwhile, hope that with the introduction of good animals, will come that of well tilled fields of roots for their sustenance; hay alone, being hardly sufficient to keep them up to that full condition so agreable to behold.

But to proceed. The sun had but little the advantage of us, in climbing up the high hills from Cherry Valley, so that we had a pretty fair meeting upon their burnished tops, and such a glorious view of the wide valley of the Mohawk, seen spread out before us, as would amply remunerate a sluggard for a whole year of early rising. The waters were shrouded in a misty wreath as far as the eye could reach; beyond, rose hill upon hill, and between on either side, waved such fields of golden wheat, tall corn and green meadows, as would gladden the heart of any one to behold. It is an exceedingly rich valley, the Mohawk, possessing great capabilities, and well may it challenge the admiration of the traveller, not only for its fertility of soil, but ever varied roll of hill and dale, and gentle flowing streams.

We found some very good Leicester sheep, at Mr. John Wilkinson's of Esperance, and the prices he mentioned for them, I thought low—they seemed to be bred with care, and the manner in which they were handled in pasture, by a well trained shepherd dog of the Scotch breed, was quite gratifying. At the farm of Mr. Dunn, at Dunnsville, we saw Liecesters also, of the largest size. One buck among them, the farmer assured me, weighed 334 lbs. To the amateurs of large animals, and to every one desirous of increasing their sizes, I recommend these sheep, but will frankly add, that they are not to my fancy at all, and I would much sooner choose a breed of half their size, even if I were desirous of raising the greatest given quantity of mutton from the same number of acres, and same amount of food. These large animals are no workers in pasture, and must stand up to their knees in grass and clover during summer, and be highly fed on roots in the winter, or it is quite impossible to keep them up to the work—so says every intelligent breeder that I have conversed with upon the subject. Mr. Dunn, residing in Albany, I had not the pleasure of seeing, to learn his opinion, which, for ought I know, may be the antipodes to the above. He also has a superb herd of dairy cows of Mr. Bullock's breed of Short Horns. They are deep and rich milkers, and on good pastures, I should consider them very valuable and productive animals.

Leaving the turnpike about two miles this side of Albany, we moved round a beautiful park composed mostly of evergreens, at the gate of the Three Hills farm, belonging to Mr. C. N. Bement. This place is greatly improved since coming into his possession; a charming house with a nicely arranged and well stocked garden in front, neat fences, and young trees planted out and flourishing in rows, where before it was all barren and desolate, and other rural embellishments are in progress, that will soon make his home, as indeed it is now, a very agreeable one to occupy.

The crops here, were better than I expected to find them on so light a soil, the oats, if any thing were too rank in growth, the rye good and the mangel wurtzel the best I have seen this year. The ruta baga also, was very promising, though in common with other crops, where I had visited, the cold heavy rains had somewhat put them back. I much liked his yard, barn, and stable arrangements, and in building for myself should copy the piggery, merely doubling the width, and making two rows of pens with accompanying yards on each side of the gangway. I found here a very cheap and simple apparatus for raising water, in successful operation. A small stream runs through the farm, across which a dam is thrown that gives a fall of 3½ feet. An overshot wheel of 2 feet 8 inches in diameter, is here placed with a pump 1¾ inches bore, and 10 inches long, forces up from 12 to 1400 gallons per day to the height of 55 feet, and 42 rods distance to the mansion house, from whence it is carried, in lead pipes down to the stock yards, piggery and barns. The water works are protected by cheap covering, from the frosts of winter, and the supply during the most intense frosts, is always kept up, making a comfort and convenience in obtaining this necessary fluid, that highly commends itself to the attention of all who are desirous of bringing water to their houses and stock-yards.

Mr. B.'s Durhams, like every other breeder I have called upon, have become pretty well thinned in point of numbers; he has however, a few still for sale. Among these I would particularly notice his yearling bull Astoria, as being of good size, and of very perfect symmetry of form. I also took quite a fancy to a large three year old heifer, the name of which I do not recollect. But Durhams as I have before hinted, I do not think the proper stock on light soils, either at the North or South. There are exceptions, but as a grand rule, they must have a luxuriant pasture that produces a good thick bite in summer, with generous feed throughout the winter, or it is idle to think that they can be kept up to good flesh and great size. I believe Mr. B. for one, is becoming convinced of this, and has accordingly procured some Devons, an Ayreshire heifer, with more expected soon to arrive from abroad, and also a few good native cows. One of these last of handsome colour, limb and shape, unites extraordinary milking qualities. From the 19th of December to the 18th of January, she made 56 lbs. of well worked butter, which is nearly 2 lbs. per day, a great yield for the dead of winter. She is what I think Col. Jaques would class among his celebrated "cream pot" breed, without hesitation. I have ever been a great advocate for the improvement of our native breeds of all description of stock, and I am glad to see Mr. B. enter upon the subject so spiritedly. Massachusetts' able Agricultural Commissioner, Mr. Colman, has shown by his reports, that we are not deficient in first rate dairy cows. These have only to be carefully selected and crossed with Durham bulls of fine points, middling size, and of deep milking families, to soon ensure as valuable a breed of dairy cows, as could be imported at ten times their expense from abroad. In this way, the Ayreshires have been made, that have become second, now only to the Durhams. Could the attention of stock breeders be better employed than turning to this subject? It really seems to me the only way that our country can ever be filled up with good milking and fattening animals. A few years of such breeding, would assuredly do more for us than a century of importations.

I here saw a pair of young Herefords, imported in May—I am not much conversant with this breed, but if these be fair specimens, as I am assured they are, when full grown, they must be very large and noble animals. They have not the fineness of head or great angle from the hip bone back, and thickness of loin of the Short Horn; they have latterly however, generally beat them in weight, at 4 years old and above; and at the Smithfield cattle show last year, I am informed, took five out of the seven prizes. Under 4 years the Short Horns attain greater size and better flesh, maturing soonest, and are far before them as milkers. The Herefords are a dark red with a white or brockled face, white breast and bellies, and occasionally line backed. They are long bodied, straight limbed, and heavy in the most valuable points, thrifty, and of good constitutions. For power in the yoke, they probably excel all other breeds, and for fine and at the same time, heavy beef, I should think they would obtain great favor with the western grazier. Mr. B. is making several experiments of crossing with all these breeds, not only on the native stock, but somewhat with each other, and will doubtless take pleasure in giving the public full particulars of the result.

The stock of sheep is highly bred, and is of sufficient variety—Merino, South Down and Leicester. Of the pigs, I need say but little, inasmuch as they have a very numerous representation abroad, that are able to speak pretty well for themselves. A new boar, from Col. Williams' late importation, has been added within a short time to the piggery. He has good points, and promises when full grown, to be of great size. His color, however, and some other characteristics are different from the old stock. It was merely accidental Mr. Hawes bringing over animals with so much black in them, as those who have long resided in Berkshire Co. England, tell me that the original color of this race abounded quite as much in white as black spots. There are other points besides color, to distinguish this superb breed of hogs, for instance, their great thickness of ham and shoulder; long straight round barrel, their hair and pointed ears, these make them recognized at once to those who are at all conversable with Berkshire blood.

A. B. ALLEN.

China Tree Corn.

Albany, Oct. 31, 1839.

Mr. J. Buel—Dear Sir—You will confer a particular favor by inserting the enclosed communication of Mr. Roberts, in the next number of the Cultivator. If ever in my power, I will be happy to reciprocate the favor.

Yours very respectfully,

W. THORBURN.

[*From the Baltimore American Farmer of October* 9.]

China Tree Corn.—There are few subjects on which such opposite opinions have been formed and expressed, as there have been in regard to this corn. Whilst in some places it is denounced as a humbug and a cheat, in others it is declared to be a valuable and prolific variety, and is considered worthy the attention of the farmer. We have heretofore published communications highly favorable to it from Mr. Sangston and Dr. Muse, and we present a second one this week from the pen of Ed. P. Roberts, Esq. who has felt it due to Mr. Thorburn to give this second testimony in his favor. We frequently hear of disappointments in the result of planting seeds, which in many cases are produced no doubt from unsuitable location, or other similar circumstances, but there is as little doubt, are as often from the want of genuineness in the seed. As we are anxious to do justice to every one, we most cheerfully give place to the communication of Mr. R.

THE CHINESE TREE CORN.

J. S. Skinner, Esq.—Dear Sir—In publishing my note on the subject of the Chinese Tree Corn, of the 31st of July last, you appended a note from a correspondent of Fairfax county Virginia, who remarks, that he had "planted two ears of the Chinese Tree Corn upon land well manured and limed—the result will prove it absolutely worthless, and more like a rush than a tree."

I have read also in your paper an article from that excellent paper, "The Yankee Farmer," whose editor affirms, that "the China Corn is a complete deception practised upon the credulous and confiding public," and adds with great severity,—and if the Chinese Tree Corn was the worthless thing represented, with equal justice, —that the author of the deception would be entitled to the severest reprehension. The same article contains the declaration of Mr. Howard, the able conductor of the Zanesville Gazette, that it was not an early corn, and that some farmers "observe that it will require two years to mature this corn."

I have no doubt that each of those gentlemen have spoken conscientiously upon this subject, and I am equally certain, from the result of my own experiment, that they have been deceived in the variety of corn they have purchased as the Chinese Tree Corn; for it is impossible that results so different to my own, could, under any other circumstances have occurred.

As I promised you in my former note that "in the fall I would measure my little patch, and give you a faithful account of its yield," I now proceed to redeem that pledge, and I do it with the more cheerfulness, as I conceive it but an act of justice due to Mr. Thorburn, that those at least with whom his corn has succeeded well, should speak of it as it deserves, in order that so far as their moral influence may go, his name may be rescued from the fate of those who practise "deception" either upon private individuals, or the public.

With these explanatory remarks, I will state its yield, and such other characteristic traits as it strikes me to possess.

My patch was planted on a plot of ground in my garden, 32 by 23 feet in dimensions, making 736 square feet. The soil was a deep rich loam, which as I described to you, I highly manured. It had the benefit of good culture, and its working was always done at the right time. On the 15th of September, I gathered and housed my little crop, consisting of 254 good ears, rejecting all the nubbins. While the corn was in the roasting ear state, as I observed in my former note, I pulled 24 good ears. If then, I add these to those I pulled on the 15th of September, it gives the product of 268 ears on 736 suqare feet of ground, and as there are 43,564 square feet in an acre, the yield calculating that each ear will shell half a pint of corn* was at the rate of 128 33-64 bushels per acre. But this is far short of the actual yield, as one of my cows found her way into my garden on the night of the 25th of August, and destroyed a considerable quantity. Besides this, my chickens depredated largely upon it. Having spoken of its yield, I will proceed to state its peculiar traits of character.

Its suckers branch out from the root, and after arriving at maturity, it is difficult to distinguish them from the main stalks, being so nearly equal in size, and so alike in appearance.

The stalks and suckers were from 9 to 11 feet high: not so thick as may be supposed from the number of suckers which were thrown out and permitted to grow, as the larger varieties of field corn, which are generally carefully suckered. From actual measurement, however, I can state that the suckers and stalks in my patch were from 3 3-10 to 4 1-10 inches in circumference, measured four inches from the ground. I planted but two grains of corn in each hill, and yet these hills had on them 10, 14, and in one instance 19 good sized ears each.

The ears have 10 rows of grain on them, are from 8 to 11 inches long, of medium thickness; the grain a beautiful pearly white flint, of great specific gravity, and from the sweetness of the roasting ears which we cooked, I have no doubt will prove an excellent meal corn, and be found to possess a very large quantity of saccharine matter. It makes, as may be presumed, a very large quantity of fodder; and on that account is desirable to a very great portion of corn planters, most of whom rely in a measure upon their cornfields to furnish winter provender for their stock.

So far from its being a late corn, and requiring two seasons to mature it, I consider it an early corn, which opinion is borne out by the fact of my having gathered and housed mine on the 15th of September, a period when much other corn is scarcely out of the milky state.

I have given the result of my own experience above, and will add, that two of my friends who made experiments with it also, speak in high terms of its productiveness. Besides these gentlemen, I observe in your paper that Dr. Muse and Mr. Sangston, of the Eastern shore of this state, are well pleased with their experiments.

I have thus discharged a duty which I owe to Mr. Thorburn, and will remark, that in doing so I have no possible interest, either of a pecuniary nature, or of feeling, to subserve. He is a gentlemen that I know not except by reputation. I have never had the slightest correspondence with him; and in all human probability never will. But it is sufficient for me to know that he is a distinguished Seedsman, and that he is the original of Laurie Todd, to make me feel solicitous about his fame, and willing, whenever that fame may be assailed with unmerited obloquy, to take up the gauntlet, couch a lance, and run the hazards of a tourney in his defence.

I will conclude this, perhaps uninteresting letter by stating, that I am so well pleased with the Chinese Tree Corn, that I have determined to plant no other kind next season as a crop corn. ED. P. ROBERTS.

Mulberry Grove, Oct. 1, 1839.

---

* I measured an 8 inch ear, the yield of which was half a pint.

Sugar.

The population of all the sugar growing countries in the world is about 403,000,000—it is estimated that each inhabitant consumes ten pounds per annum—amounting in all to 4,680,000,000 lbs. nearly four times as much as is consumed in Europe, and in the United States. Great Britain consumes 400,000,000 lbs. or 24 lbs. to each inhabitant—the United States 200,000,000 lbs. or 16 lbs. to each inhabitant—our domestic production being estiat 50,000,000 lbs. In Ireland the consumption is 40,000,000 lbs. or 6 lbs. to each inhabitant. In Russia it is still less, being 60,000,000 lbs. or only about a pound to an inhabitant. Of the quantity consumed in Russia, it is supposed that 8.000,000 lbs. are beet sugar. Belgium consumes 30,000,000 lbs. or 7 lbs. to an inhabitant, of which 5,000,000 lbs. are beet—and Prussia, Austria and the east of Germany, 200,000,000 lbs. or four pounds to an inhabitant, of which 20,000,000 lbs. are beet. Holland consumes 50,000,000 lbs. or 16 lbs. to an inhabitant. Spain the same quantity, or almost 4 lbs. to an inhabitant. France, 230,304,549 lbs. or 7 lbs to an inhabitant —of this, 107,905,785 lbs. were, in 1836, manufactured from beet roots. Thus we have, for the total consumption of sugar in Europe, 1,267,000,000 lbs.—of which 140,000,000 lbs. or 62,500 tons are beet sugar—and for the annual consumption throughout the world, 6,267,000,000 lbs.—worth, at 6 cents a pound $376,620,000.

Margraff, a Persian chemist of Berlin, made the discovery nearly a hundred years ago, that the beet root contained a good crystalizable sugar. After this he enlarged and varied his experiments, but did not invent means of making sugar from the raw material, on a scale sufficiently large to render it an object of interest to capitalists. He died in 1782. It was Archad, also a chemist of Berlin, who discovered the method of extracting sugar from the beet on a large scale, and at a moderate expense. He first announced this result in 1797. The National Institute of France, appointed a commissioner to examine into the subject. Manufactories were established, but were not successful—and the high hopes which had arisen, of this new branch of industry in France, seemed destined to disappointment.—Political events, however, afterwards favored the attempt to find an indigenous source for the supply of sugar, and after many experiments, the preference was given to the beet. In January 1812, Napoleon issued a decree establishing five chemical schools for teaching the process of beet sugar making—detaching one hundred students from schools of medicine, pharmacy and chemistry, to be instructed in those establishments, and creating four imperial manufactories, capable of making 4,408,000 lbs. of raw sugar annually. Premiums were also awarded to persons who had already distinguished themselves by a successful application to this new branch of industry—and an impulse was thus given to the manufacture of beet sugar throughout France. The battle of Waterloo gave a great shock to this branch of industry, but some of the sugar establishments continued to thrive after this action; and in 1818, after the allied troops had left Paris, the government began to turn its attention towards the encouragement of an industry, which had struggled meritoriously and successfully, to preserve a boon to the French nation. It has already been stated, that in 1836, 107,905,785 pounds of sugar were made from beet roots.—*North American Review.*

Cost of Raising Sugar Beets and other Roots.

In examining an estimate of the expenses of making beet sugar in this country, many farmers will consider that the expense of raising the roots is reckoned too low; this is owing to the little attention that has been paid to root crops, and to farmers in general not being acquainted with the best and most economical method of culture, and not having machines and implements to enable them to manage the growing of root crops to advantage.

These unfavorable opinions will in a measure continue, till root culture is more in practice, for though cases are stated of crops raised at a small expense, they will be regarded as extraordinary cases, and estimates made on paper, in which no error can be pointed out, will be looked upon as something uncertain; yet these favorable accounts will lead the enterprising and intelligent to try and see whether these things are so, and although their expectations may not always be realized, yet they will find a great advantage in attending to root culture and be led to inquire into the most frugal method of pursuing it. Farmers who dig up a small patch and sow it in beets, and do not weed it till there are five hundred weeds to one plant, may find that the cost of raising a bushel of beets is one dollar, when with prudential management in raising on a large scale, ten to twelve bushels may be raised with this expense.

In raising beets and some other crops in a garden we have managed to do the weeding before sowing, and find that it is a great saving of labor: that is, pursue that manner of culture that will destroy the weeds before the seed is sown; and the same plan may be followed in field culture, and even to greater advantage, as most of the labor can be done by animal labor, which is much cheaper than manual labor in this country, and this, as has been observed in the articles lately published on the subject, will enable us to raise beets as cheap as they are raised in France.

Our method has been to put on the manure and stir up the ground in the fall or early in the spring, the former is preferable, as a frost will loosen the soil and make it mellow, and the weeds will start in the spring before the soil is dry enough to work. When the weeds were well started, we worked the ground over again. About the 20th of May the ground was well worked over, and the seed sown, after being soaked, so that it would come up in a short time; the plants were up and large enough to hoe when scarcely any weeds appeared, the hoeing was done in a short time, the soil being very light and mellow, and there was but little trouble on account of weeds through the season, they having been mostly destroyed before sowing. If this plan should be pursued in field culture it would save nearly one-half of the expense. One hour's work with a horse and cultivator in stirring the earth and destroying weeds before sowing, would save several days in hoeing.

The following method of culture for a field crop would be very economical as to weeding, which seems to be the most expensive part of the cultivation. A piece of land, a deep mellow soil that has been well manured and planted one year in corn or potatoes, would be in good condition for a beet crop. If it has been ploughed more than one year there would be danger from the grub worm, which, we believe is the principal injury from insects to which the sugar beet is liable.

A piece should be selected that can be ploughed deep, and the stones, if any, removed. If there has not been sufficient manure applied to the previous crop, apply the manure and plough the ground very deep in the fall; if it cannot be done at this season, then as early as possible in the spring. When the weeds have started, go over it with a cultivator, and in a few weeks go over it again in the same way, this will loosen and pulverize the soil and destroy the weeds. From the 20th of May to the 1st of June, let the earth be thoroughly stirred with a cultivator, or if the soil be not very loose it may be well to plough it again, then go over it with a light harrow to make the surface level and smooth, and the soil fine; be ready to sow as soon as the ground is prepared while the surface is moist and that the plants may get the start of the weeds. Pour water as hot as can be borne by the hand, on the seed and let it soak a day and a half or two days, then it will vegetate and up, and the plants will be large enough to hoe before the few weeds are liable to grow up, so as to be much trouble.

Sow the seed with a machine and the expense will be light. Let the rows be from two to two and a half feet apart, then a light cultivator may be used between the rows; in thinning the plants let them stand about one foot apart. If any places are vacant from the seed not growing or the grub worms eating them, the deficiency may be supplied by transplanting; though transplanted beets do not form so handsome a root, yet they yield about as much as the other. The expense for weeding and loosening the soil will not be great. In harvesting if the beets cannot be pulled easily, a furrow may be ploughed near each row with a horse plough, then they may be pulled with little labor. By this, or some better way if it can be devised, beets may be raised at a small expense, and as lands and animal labor are cheaper here than in France, and as much labor can be done here by animals which is performed there by the hands, we think our advantages are equal to that of France in the cheapness of manual labor. But supposing our advantages in raising the beets are not equal as to a cheap production, we have reckoned the expense higher in the calculations we have published so as to conform to a fair estimate on all expenses. Instead of $3.50 per ton as in France, we have reckoned at $5 per ton. No calculation on the expense of raising beets or other crops can be made exactly suited to all parts of the country, as the prices of labor and land are different. Near cities and large towns, and near the seaboard owing to good advantages for markets and communication, lands are higher, and the rent of them more of course than in the interior; in such cases labor too is usually somewhat higher.

Estimated expense of an acre of Sugar Beets.

Use of an acre of land well prepared for beets and manured, or managed in the previous crop,....	$12 00
Ploughing,..................................	4 00
Cultivating, horse, cultivator, and hand 2 hours,	50
Twice more before sowing,..................	1 00
Seed $2.25, sowing with a machine, 75,........	3 00
First hoeing,................................	4 00
Second hoeing, thinning, and transplanting to supply deficiencies,........................	4 00
Hoeing again and loosening the ground with machines,................................	2 00
Harvesting,................................	9 00
	$40 00

Make the rows 2 feet four inches apart, and then a cultivator can be used in hoeing. If the beets stand one foot apart in the rows, and weigh 2¼ lbs. each, the yield will be 20 tons. In rich ground, at that distance, a great number will weigh 4 or 5 lbs. each; twenty tons is a good crop, probably a large crop, but not extremely large for in some cases 25 or 30 tons to the acre have been raised in this country. At the above expense of $40 to the acre with a yield of 20 tons the cost would be two dollars per ton. We make this estimate to show how cheap beets may be raised under favorable circumstances, such as good land at a fair price, convenient machinery and implements, and the most prudential management in the culture, with labor at a moderate price, and a favorable season. We have no doubt that in some parts of New England beets could be produced in great abundance at the above price; but we must not always expect a combination of favorable circumstances.

Supposing we reckon the produce only two-thirds as much as above, say 13⅓ tons and the cost 33⅓ per cent more, which will be 53.33; then the cost of the beets will be only $4 per ton, one-fifth less than Mr. Bosson reckoned in his calculation on the cost of the beet sugar. If we reckon 50 pounds to the bushel, 13⅓ tons to the acre would be only 533 bushels which would be no more than a middling crop; not half so much as has been raised in a number of cases that have been named.

Flemish Husbandry.

AN ACCOUNT OF SOME SELECT FARMS.

The details of Flemish husbandry cannot be better explained than by reference to a few of the best cultivated farms in different parts of the country. There is a great uniformity in the general practice, but there are considerable variations introduced in consequence of the diversity of soil and situation. One of the first farms we shall notice is situated within a mile of Courtray, and is in the occupation of a man who has more theoretical knowledge of agriculture than most other Flemish farmers; he is a native of France, but has passed a great part of his life in Flanders; and his wife, who seems very active and well acquainted with the details of a farm, especially the dairy, is a Flemish woman. The place where the farm is situated is called Walle. The extent is thirty-six bonniers, each bonnier being about three acres. The soil is a good sound loam, which, although it is there called a strong soil, would not be reckoned very heavy in those counties in England where the clay prevails. It is such land as may be seen in parts of Essex and Hertfordshire, which will produce good beans, without being too heavy for turnips, or even carrots. The quality of the soil does not vary materially through the farm. It is not of so rich a nature as the clays of the polders, and, when washed, contains a considerable portion of silicious sand; but it has been enriched by repeated and ample manuring, not only by the dung and urine of the cattle kept on the farm, but by purchased manure of every description, especially the sweepings of the streets of Courtray and the emptying of privies.

The farm-buildings are very conveniently arranged at a small distance from the high road, from which there is an approach by an avenue of trees. The farm house, which is substantial and convenient, and the stables for the horses, occupy one side of a square or rectangle of sixty yards long by fifty wide. Opposite the house stands a roomy barn, and another occupies two-thirds of the west side of the square. The east side is taken up with a cow house, ox-stalls, and other useful buildings. The entrance is by a gate-way with double gates, at the north-east angle of the yard. A paved causeway ten feet wide runs all round the farm-yard, raised about eighteen inches above it. The cow-stall, barns, &c. are on a level with this causeway: and the yard slopes gently towards the middle, where there is an oval tank surrounded by a brick wall, which rises two feet above the yard. There is an opening in this wall sufficient to allow a cart to be backed into it: from this opening the bottom slopes to the further end, where it is three feet deep. This is the *croupissior*, into which all the liquid part of the dung runs, when it is washed by the rain, through openings left in the wall which surrounds it.—The urine is collected in another large vaulted reservoir immediately under the cow-house and ox-stalls.

This description applies equally to most of the farm-yards attached to large farms; for one hundred and twenty acres is a large farm in Flanders.

Thirty cows are constantly kept on this farm, and six horses, besides young heifers and colts. The cows are always kept in the stalls, and fed with green food in summer, and roots with meal in winter. Each cow has a stall in which she is tied up by herself, separated from the next by a large flat slab of stone about four feet square set on edge. There is a low stone trough before her, and an opening in the wall to give her air. She is tied by a leather strap round her neck, with a chain fastened to a staple, which goes through the wall and is secured by a nut and screw on the other side. The cow-stable is forty yards long without any division, and six yards wide, so that there is much room behind the cows. In the middle against the wall is a pump to supply water for the cows and to wash out the stable, which is very frequently done, the whole being swept into the urine-tank below through an aperture, towards which all the gutters slope from the cows stalls. Under the pump is a stone cistern, which is constantly kept full, that the water may acquire the temperature of the air. In this cistern bean or rye meal is mixed, in the proportion of a large double-handful to three gallons of water, so that the cows never drink the water without this addition. It is supposed to increase their milk and make it richer. Outside of the building is the pump, by which the urine is raised to fill the casks in which it is conveyed to the land. Another pump is in the centre tank, by which the dung water is raised, either to mix with the urine when rape-cakes have been dissolved in it, or to pour it over the solid dung to accelerate the putrefaction. The pens for fattening calves, are placed along the wall behind the cows, and, being only two feet wide, take up very little room; there are only two or three of these, for, so near a considerable town, the fatting of calves is not so profitable as selling fresh butter.

A few acres of grass are kept in permanent pasture near the house, and the cows are put there for a few hours every day in summer, more for exercise, and for the sake of their health, than for grazing. All the rest of the land is arable, and cultivated very strictly according to a regular rotation. Mr. Doutreluinge, the occupier, informed us, that he had several times made experiments by varying the usual course; at one time increasing the quantity of flax, and at another that of colza; but he found, by keeping very exact accounts of the expense and produce, that every deviation caused a loss in the end. The rotation is very simple. The whole of the arable land he divides into six parts—one part is half in flax and half in colza, one wheat, one rye and turnips, one oats (five-sixth of which with clover-seed,) one clover, with a small proportion in potatoes and carrots, one two-thirds wheat and one-third beans.

The land intended for flax is ploughed soon after harvest with a very shallow furrow, or only well harrowed to destroy the stubble; rotten dung is spread over it, at the rate of twenty large loads per acre, about the month of September. It is left spread on the land for some time, and then rolled with a heavy roller: this is to press it into the ground, and make it fine. It is then ploughed in with a shallow furrow. When the plough has made a furrow, six or eight men with spades dig spits of earth out of the bottom of it, which they set upon the part already turned up, so that the ground is partially trenched. The plough on its return fills the holes thus made, and, when the whole is finished, it lies in a very rough state with large clods all over it; so it remains all winter. In spring, when the clods are pulverized by the frost, the harrows pass over repeatedly and level the surface. The land is then ploughed and harrowed several times, till it is thought sufficiently fine. Liquid manure is now put on. This consists chiefly of the emptyings of privies and the urine of cows, and also of rape-cakes dissolved in urine, and left to ferment for some time, which is done in the open tank in the yard. The quantity of rape-cake used depends on the supply of *vidanges*, which are preferred, the other being only a substitute. This is allowed to soak into the ground for a few days. It is then well harrowed, and the linseed is sown at the rate of about three bushels to the acre, and covered by the harrows reversed or the traineau. The only peculiarity in this process is the spreading of dung over the land and letting it remain some time before it is ploughed in. According to the prevailing opinions, we should say that a portion of it must evaporate and be dissipated. But the practice must not be hastily condemned on mere theoretical principles. It is well known that there is no manure so good for flax as that which is collected in the towns by poor people, who sweep the streets, and make composts of everything which is capable of putrefaction. This compost is sold, in a dry state, by measure; and we have repeatedly seen the preparers of this manure spread it out in dry places in the sun to bring it to a marketable state. Probably the origin of this may have been that, by being dry, the carriage of it is lighter; but that the virtue of the compost is not lost by drying appears from the reputation it has amongst the farmers, who piously believe that its extraordinary effects are to be ascribed to a peculiar blessing of God, as it enables the poor and destitute to gain a livelihood. It must be recollected that this manure is so prepared by repeated turning and watering, and that the vegetable fibres in it are almost entirely decomposed. It is probably that in drying nothing is evaporated but simple moisture. This practice being peculiar, and not very generally adopted, renders it more deserving of notice.

A little beyond Courtray along the Lys, towards Menin, is a farm particularly noticed by Mr. Radcliffe in his report of the husbandry of Flanders. It was then in the occupation of a Mr. Van Bogeart, who afterwards retired with a competent fortune, chiefly acquired by farming. It is now occupied by Mr. De Brabanter, who cultivates it very carefully, with some slight deviations from the practice of his predecessor. This farm is called Vollander, and is one of the finest and most compact we have seen. It consists of about one hundred and forty acres, of which about twenty are fine meadows along the river, occasionally flooded in winter, but not irrigated; about ten acres are rich heavy land, adjoining the meadows, in which beans and wheat thrive well; all the remainder, about one hundred and six acres, or rather more, lie in an oblong field bounded by a hedge-row, at one corner of which, nearest the river, stand the farm-buildings. A road or path, six feet wide, runs through the middle of the field, and the road which leads to the farm-yard skirts one end of it. The soil of this field is a rich light loam, which lies over a substratum of clay, but at such a depth as to be perfectly sound and dry. It is not extremely fertile in its own nature, but has been rendered so by many years of an improving husbandry. Every part of the land has been repeatedly trenched and stirred two or three feet deep; and the immense quantity of manure, chiefly liquid, put on year after year, has converted the whole into a very rich mould. The strength and vigour of the crops bear witness to the goodness of the husbandry. As we walked along the middle path, which is just wide enough to admit the wheels of a cart, the whole produce might be seen at once. It was just the time when the flax had been pulled, and remained stacked on the ground. The colza had been beat out, but the stems remained in heaps where they had been cut. There were fifteen acres of most beautiful flax of a bright straw-colour, and the stems a yard long. This, besides the seed, was worth in the stack from 25*l*. to 30*l*. per acre; twelve acres of colza had produced about fifty quarters of seed; eighteen acres of oats looked so promising, that they could not be set at less than nine quarters per acres; eighteen acres of wheat, which stood well with short but plump ears, we valued at five quarters per acres; eighteen of rye, partly cut, with the straw above six feet high, would probably produce rather more than the wheat. There were six acres of white poppy, of which every plant was strong and upright, and the ground under it as clean as a garden; we are no judges of this crop, but we were informed that the expected produce would be about seven or eight hectolitres (twenty to twenty-three bushels)* per acre; six acres were in potatoes, expected to produce eight hundred hectolitres (two thousand two hundred and seventy bushels:—three hundred and seventy-eight bushels per acre.) A small patch, about an acre, was in carrots, which looked fine and large; twelve acres were in clover, nearly the whole of which was cut green to give to the cows and horses; it produces three good cuts in the year where it is not allowed to go to seed. The ten acres of heavy land were partly in beans and partly in wheat.

Thus we have one hundred and sixteen acres all profitably cropped, leaving four acres for the roads and farm buildings. Although this farm is within two miles and a half of Courtray, the greatest part of the manure is collected on the farm. Rape-cake is used more profusely, and to this, as well as to the depth of the soil, the beauty of the flax is ascribed. Mr. De Brabanter usually sows his flax after oats, which, on this account, have been very highly manured. His urine-tank is very capacious, like a large cellar under his cow-house. The farm-buildings are arranged nearly as those of the last described farm; he has a large dry vault to store his roots in winter. His stock consists of twenty-seven cows in milk, five or six heifers, nine horses, and three colts. The rent of this farm, including land-tax and other imposts paid by the tenant, amounts to 4880 francs, 187*l*. 15*s*. which is fully equal to 270*l*. in England, taking the value of agricultural produce in the two countries as a measure.

There is nothing very peculiar in the practice of Mr. De Brabanter. He ploughs the land well, lays it in narrow stiches with deep intervals dug out by the spade, puts manure with every crop, more or less, keeps the land clean by weeding, and adopts a long and varied rotation.

The beauty of this farm consists in the equality of the soil of the great field and its depth. This is not so much owing to natural advantages, as to a long course of stirring and manuring, by which there is such an accumulation of humus, as to render a sandy loam, naturally of moderate fertility, equal to old garden ground, absorbent and retentive of moisture, without being wet. The labourers on this farm were mostly lodged and boarded in the house, and they had all the appearance of being healthy and well fed. The farmer himself is a tall athletic man, with a good-natured, but shrewd countenance; he seemed very ready to give every information respecting his farm. His wife, equally active, superintends the dairy, and took some pride in showing us in a cool vaulted cellar numerous pans set on the brick floor filled with the last milking, and deeper vats in which the milk of the preceding day had been put in its progress towards churning. The milk, even when it is not intended to be skimmed, is always set in shallow pans for twelve hours before it is poured into the vats, and the different milkings are kept separate.

The next farm which we shall notice is somewhat different from the two preceding, and if the land is not quite so carefully tilled, it is made very productive from the quantity of stock kept upon it. It is situated between Furnes and Dixmude, at a place called Stuiveskenkerke. It partakes of the nature of a polder farm; for the land may be considered as an old polder. The extent of the farm is considerable, upwards of four hundred acres, of which two hundred are in rich natural pastures, the remained is cultivated with the plough. The soil is here a good stiff loam, having the appearance of clay; but it approaches more nearly to a marly soil, which crumbles when moderately wetted. It contains a considerable proportion of calcareous matter mixed with sand and clay, and is decidedly of a superior quality to that of the two preceding farms. It requires less manure, but is more difficult to cultivate; both the extremes of wet and dry in the weather rendering the plough useless. In the first case the surface is converted into mud, and in the latter it cannot be ploughed; for if sufficient strength were applied, it would rise in large clods, which would harden in the sun, and remain so till continued wet or frost crumbled them again.—Wheat and beans are principal crops, and the latter are more carefully cultivated than we have seen in any other part of Flanders; they are planted in rows, in imitation of kitchen-gardeners. A drill is drawn with a hoe, and beans are deposited in it three or four inches apart; the earth out of the next drill serves to cover the seed. The distance between the drills is about ten inches or a foot, which in rich land is too near. When the beans are out of the ground the intervals are hoed. The produce is from three to five quarters per acre, but might be more with wider intervals, and more effective hoeing.

The rotation of crops on this farm is generally—1 fallow; 2, winter barley; 3, beans; 4, barley or wheat; 5, beans, clover, potatoes; 6, wheat; 7, oats. The fallows are not ploughed before winter, but four times in spring and summer. Thirty cart loads of manure in a long state, without the straw being much decomposed, are put on before the last ploughing, and the winter barley is sown in October; the produce is eight quarters per acre. Wheat on the same preparation produces from four to five quarters, so that the land is better suited for barley, and this last gives a better return with less exhaustion of the soil; every year a small portion of the pasture is broken up, and sown with colza. This would probably not have been permitted, had the farm not been occupied by the son of the proprietor.

---

* A hectolitre is 2.837 Winchester bushels.

The natural fertility of the soil is shown by the succession of the crops produced on the newly-broken-up land without any manure; viz. colza, wheat, beans, barley, beans, wheat, clover, wheat, beans, oats. After this scouring is it no wonder that the soil wants rest; and this is given without much care, by merely allowing the natural grasses to spring up without the trouble of sowing the seeds. It takes three years before there is any tolerable pasture; but as it remains twenty years or more in grass before it is broken up again, the deteriorating effect of the cropping is not observed. How much more productive might not the land be made by more judicious management! The whole of the farm has repeatedly undergone this process, and must have been extremely rich at first. At present it requires repeated manuring to produce even average crops, except on that portion which has been broken up from old grass. Under a regular and judicious course of convertible husbandry, this land might be kept up in the highest state of fertility, and the ultimate profit would be much greater.

If we cannot altogether praise the management of the arable land, we must do justice to that of the dairy and stock. Here the finest and richest butter in the world is made. The stock consists of twenty-four milch cows, twenty-eight yearling calves, twenty-eight two-year-old heifers and steers, and fifty bullocks. All these are wintered on straw, hay, and split beans. The straw is cut into chaff, and the farmer, Mr. Graeve, son of the proprietor, a spirited young man, has procured from England a machine for cutting chaff, which is to be worked by a horse, in the same mill by which he churns his butter. The bullocks are fattened on the pastures, and are fit for the butcher by the end of July or August.—The weight of the carcass, when slaughtered, averages ninety stone, of eight pounds each, and sells for 12*l.* or 2*s.* 8*d.* a stone. The cows give each, on an average, twelve quarts of milk per day. He churns three times a week, making forty pounds at each churning. The cream only is churned in a barrel-churn, which is turned by a horse. The butter comes in one hour and a quarter in summer; in winter it takes two or three hours.—As soon as it is taken out of the churn it is well washed, to get all the butter-milk out, and immediately salted: before night it is worked again, and more salt is added. It is then put into the cask, and brine is poured over it. It sells for one franc (10d.) the pound of twenty ounces. This butter is famed for its keeping, and is therefore much sought after for ships' provision. In summer there are fifty labourers on this farm, half of whom are boarded and lodged, and have from 8*l.* to 12*l.* yearly wages. The day labourers have 9d. a day and their food.

The calves which are reared, of which there were twenty-eight when we visited the farm, have per day a bushel of oats and eight oil-cakes amongst them, with hay and cut straw, from November to May. The fifty oxen have a sack of beans per day amongst them, and cut straw as much as they can eat. There were two hundred sheep, which are folded on the fallows, and in the day-time feed in the pastures and along the canals and dykes. When they are fat they are sold and others bought in. None are bred: for, when kept long on this land, they become subject to the staggers and the rot in winter and spring; they are therefore fattened and sold as soon as possible.

The breed of pigs was much better than the generality of Flemish pigs, and appeared to have had a foreign cross, perhaps of a Berkshire hog; but there was no distinct account of this. The short legs and pricked ears clearly prove them not to be indigenous.

The cows are dry for three months in the year; at that time they have only straw to eat, with a small quantity of meal diffused in the water they drink. They calve in April or May, and, when the grass becomes abundant, each cow is expected to give five pounds and a half of butter weekly; and as the pound is of twenty ounces, this is a large average, and shows good pasture.

Hay is made more carefully and better stacked on this farm than we have seen it on any other. The ricks are square, as they are in England, and hold from forty to fifty tons of hay; they are carefully thatched, and want only the pulling and trimming of the ricks in Middlesex, to vie with them in neatness.

There are seventeen horses kept for farm-work; these are mostly of a French breed, much more active and vigourous than the heavy Flemish horses. A good horse costs from 16*l.* to 20*l.* The cows are mostly Dutch, and cost from 8*l.* to 10*l.* each. They are large and have fine udders. The colour is generally black and white, the horns moderate, and the skin fine. They are not so high as the Holderness cows, but their carcasses are as large; some of them give an astonishing quantity of milk.

This is one of the largest farms in Flanders, and may be considered as an intermediate between the upland farms and the polders. The buildings are scattered and irregular. It was formerly the property of a religious order, but confiscated and sold at the Revolution in 1794. The chapel still remains, but it is converted into a barn. The tenant purchased the land for a small sum compared to its worth, and his son is the present occupier. A small canal winds through the property, acting as a drain for the superfluous water, and at the same time as an easy means of conveying the produce of the farm-yard, and taking manure to the fields bordering upon it. With a little attention it is not difficult to make this farm produce everything that a frugal Flemish family requires, and enable the occupier to lay up a considerable sum every year. In the hand of a skilful and scientific farmer a fortune might be realized on such a soil in a few years, by keeping up the fertility, instead of reducing it by excessive cropping of the land broken up from pasture; but especially by introducing improved breeds of cattle, and grazing them to advantage.

Not far from Roulers, at Newkerken, there is a small farm of about sixty acres, occupied by a Mr. Verpoort, which is worth noticing. The soil is a good sound grey loam of a moderate quality, the subsoil being retentive; the fields are divided by ditches four feet wide and three deep. Some trees and underwood are planted along some of the ditches but not everywhere. There are no raised banks; the earth of the ditches having been spread over the land. The fields are all small, not exceeding three or four acres each, and mostly of an oblong shape. There was no water in the ditches when we saw it; but it is probable that in winter they are necessary to keep the land dry, as the country is so flat that the water must be a long time in running off. The principal produce on this land is wheat, of which there are eighteen or twenty acres every year. The wheat this year (1837) was sown on land which the year before had been cropped as follows: two acres in beans, four clover, two potatoes, three colza, three flax, and four fallow—eighteen acres in all. Mr. Verpoort, thinks that it might be more advantageous to have more fallow, as the land is very apt to be overrun with weeds, in spite of every precaution, and a fallow now and then is unavoidable. The other crops besides wheat where distributed as follows: three acres in rye and turnips, four oats, five flax, three colza, four and a half clover after flax, two beans, three potatoes, half an acre beet-root, five fallow, ten grass, half of which was pastured, and half mown. These ten acres lie along a low rivulet, and are flooded in winter. What makes this farm worthy of notice is the great proportion of wheat sown, and the variety of other produce, which return at a much longer interval, clover only every nine or ten years.

The whole of the work of this farm is done with two horses. There are thirteen fine cows, four heifers, two or three calves, one colt, and five or six hogs; and all these animals seem well fed. Except a few grains from the brewers, and some linseed cakes, no food is purchased for the cattle, but the farm supplies all that is required. Mr. Verpoort used to breed horses and sell them to English dealers, who came round to the different farms, and bought three-year-old colts at a fair price; but none of them had been there for some time, at which he was disappointed, having a very promising colt eighteen months old, very large and fat, which he thought would be much admired. The colt had been brought up in the stable, like a fatting calf, without much exercise. His feet were flat and wide; and, from good feeding, he was large and heavy. He might at one time have been admired as a heavy dray-horse, but he was evidently very unfit for muscular action; and although as well shaped as most Flemish horses, he was not likely ever to become very useful.

The cows on this farm were milked three times a day for three months after calving, and only twice afterwards. They were fed in summer with clover cut for them and brought into the stalls. Occasionally they were led out into the pasture, but only for a few hours at a time, and never in the middle of the day, when the flies would teaze them. In winter they had their brassin, made of turnips and potatoes cut in pieces, and chopped straw, boiled together in a copper, and some linseed cake added to this. Sometimes beans were soaked in water for twenty-four hours, and then mixed with the brassin. The roots were cut by a machine something like our turnip-cutters, but not so perfect.—This is the only farm where we have seen a machine, as the spade is the usual instrument with which roots are cut. The chaff-cutter is exactly like our common chaff-box, where the work is done by the hand; and, except where horse-power can be applied, or the chaff-cutter can be attached to a mill, the hand-box is, perhaps, the instrument which will cut most chaff in a given time by mere manual labour. The cows are of the Dutch breed, and apparently very good milkers. Mr. Verpoort fattens calves a twelvemonth old, and thinks it more advantageous than if he kept them longer. This young beef is probably more readily disposed of in Flanders than it would be in England. All the labourers on this farm are fed in the house. The women have five-pence and the men eight-pence a day for wages, which makes the food to be reckoned at only three pence per head per day. A labourer obliged to find his own food could scarcely provide himself at so cheap a rate; but the farmer, who has everything from his own farm, finds that it is more economical to feed the labourers, even at that low rate. They have for breakfast bread and potatoes, with *tea* as it is called, but it is a very weak infusion of that herb, and may be better called hot water with milk in it. For dinner they have a soup of butter-milk and bread boiled in it; after that they have potatoes and a bit of salt pork. For supper skimmed milk or butter milk and potatoes.

The hogs are kept in separate dark styes, and fed on beans and the remnant of the brassin. They are six months or more in fatting, and then not remarkably fat.

The whole farm is in very good condition and clean. The beans are sown in the furrows after the plough; the produce per acre, on an average, is four quarters of wheat, seven of oats, four of beans. All the roots are consumed on the farm. The land does not suit barley so well as wheat. The clover is usually sown amongst the wheat in spring. Flax is sown after oats, and colza after rye and turnips, which two last always come after wheat. This seems to be the most universal practice all over Flanders.

No sheep are kept on this farm; but a neighbouring farmer, who has eighty acres, keeps one hundred sheep which he fattens, not by pasturing them, but by feeding in the stable like oxen. They have clover cut for them, and sometimes partake of the brassin. They get fat, but whether the flesh is well tasted when they are killed, is more than we can say; the principal object is profit, of which the dung forms an important item.

On another farm situated near Grammont, the property of Mr. Spital, who is a great *amatuer* and breeder of English blood-horses, we found the soil of a still stronger nature, but the cultivation very similar to the last. The name of the tenant is Vander Stude, a sensible and intelligent farmer, who seems to be well acquainted with the practice of the best farmers. He holds about one hundred and thirty acres of land, of which three-fourths are arable and one-fourth pasture. A third of his arable land, or about thirty acres, is in wheat, ten rye, fourteen oats, fourteen clover, ten flax, twelve colza, three beans, three barley, and six in potatoes.—There is no fallow, yet the land is clean. It seems not so wet as the last, and this may account for the fallows not being so necessary. He sows turnips after rye or colza. The colza plants are raised on the land which has had clover upon it, with one ploughing. The flax is sown in March, on clover ley also, with only one shallow ploughing, which is given before winter; but the land is repeatedly harrowed before the flax is sown.—Everything which is grown on the farm, except wheat, flax, and rapeseed or colza is consumed upon it. His urine-cistern is twenty feet square, and seven feet deep, but he says that it is much too small. There is a smaller cistern under the dung in the yard, from which the drainings are occasionally pumped up, and spread over the dung to accelerate its decomposition. The produce of the land is from four to five quarters of wheat per acre; the same of colza: but this last is worth one-fourth more than the wheat. The flax is sold on the ground at about sixteen pounds an acre, the farmer feeding the labourers who pull it;—this is a lower produce than where the land is differently prepared for this crop.

The stock consists of seventeen cows, five calves, and a few heifers, nine cart horses, and three colts. The labourers are fed and paid exactly as at the last farm. A few hops are grown on about half an acre.

Near Alost we met with one of the smallest farms, which will maintain a family without other work; it was barely five acres. The house was much larger than such an occupation warranted; but it was an old farmhouse, and the land had been divided into small holdings, leaving only five acres to go with the house.—There was a small orchard of about a quarter of an acre, in whch there were some thriving apple and plumb trees. The grass under these was good; and the only cow which the man had was led by the wife to graze there for a short time every day, apparently more to give her exercise than for the food she could pick up.—The grass seemed to have been cut for her in another part. This cow had cost eight pounds, and the man regretted that he had not had the means to purchase a second, as he could have maintained two very well. Half of the land was in wheat, the other half in clover, flax, and potatoes; so that the clover did not recur sooner than in six years, the flax and potatoes in nine. As soon as the wheat was cut he began to back the stubble about four inches deep with the heavy hoe, and as fast as he got a piece done, it was sown with turnips, after having some of the contents of the urine-tank poured over it: for, small as the farm was, it had its reservoir for this precious manure. Thus a considerable portion of the wheat stubble was soon covered with young turnips of a quick-growing sort, which, if sown in the beginning or middle of August, were fit to be pulled in November and December, and stored in the cellar for winter use. There was a small patch of cameline, which was sown less for seed than for the stem, of which he made brooms in his leisure hours in winter.—But these hours could be but few, and only when snow covered the ground, and prevented him from digging and trenching, which was a constant operation; for the whole five acres had to be dug in the course of the year, and as much of it as possible trenched; the soil being a stiff loam of a good depth, which was much improved by trenching and stirring. The milk and potatoes fed the family, with the addition of a little salt pork; for a pig was fed on the refuse of the food given to the cow, and a very little corn, and consequently was not overburdened with fat. Most of the wheat and all the flax were sold, and more than paid the rent, which was not high—about 10*l.* a year without any rates, tithes, or taxes. Incessant labour kept the man in good health, and his wife was not idle. They had two or three young children, one at the breast: but, except the wish for another cow, there seemed no great dissatisfaction with their lot, nor any great fears for the future. They had no parish-fund to fall back upon, not even a union workhouse; but had they come to want by unforseen accidents, they would have found the hand of private charity stretched out to help them.

We have before alluded to a farm of which the occupier kept ewes for the sake of their lambs, which he alone in the neighbourhood fatted for the butchers. His name is De Keyart, and his farm is situated at a little distance from the neat and flourishing village of Hamme. It consists of sixty-five acres, of which five are meadow, near a little rivulet. The ewes are kept as another farmer would keep cows. He considers the keep of one hundred sheep as equal to that of fifteen cows. He has however, five cows, also; and three horses to do the work of his farm. His rent is about thirty shillings an acre,—a considerable rent, but small in proportion to the price of land, which here sells at an extravagant rate, not paying two per cent. for the outlay. Hamme is in the Waes country, where the cultivation is carried to the greatest perfection. One-sixth part of Mr. Keyart's farm is trenched two spits deep every year, which costs him 30 francs—about 1*l.* 5*s.* per acre. This shows that the land is light, and the trenchers expert, to be able to do it at that price. The first crop on the trenched ground is potatoes, after the land has had twenty tons per acre of good yard dung spread over it. This is ploughed in four inches deep. After a fortnight an equal quantity of dung is put on and this ploughed in seven or eight inches. It must be observed that in ploughing the ground is turned completely over, so that the dung lies under the furrow-slice. The second ploughing does not bring the dung first laid on the surface again; but the point of the share, going four inches under it, lifts it up enclosed in two layers of earth; that which had been above the first dung is turned down upon the last portion, and the four inches last raised are turned to the surface, so that there are two distinct strata of dung, if we may so express it, one four inches under the surface, and the other eight. The advantage of this method must be obvious; and the ploughmen who can execute it should not be despised. Potatoes are planted on a part of this ground, and hemp sown on the remainder. The potatoes are put into holes made with a blunt dibble, and it will be perceived that if they are put in six inches deep, they are placed between two layers of dung, and cannot fail to grow readily in such a rich and mellow bed. When the potatoes are fairly up out of the ground, the earth is stirred and raised around the stems, and liquid manure is poured on the little heaps thus made. It is not surprising that with so much manure a great crop should be produced: but this manure is not all put in for the sake of the potatoes only, but for the flax, which is to follow, for which the dung should be well incorporated with the earth, and the land very clean. For the flax rape-cakes dissolved in urine, or what is preferred—*vidanges*, form the chief manure. Carrots are sown soon after the linseed, if not at the same time. In weeding the flax great care is taken not to pull up the young carrots; when the flax is pulled the carrots are already very forward, and by the help of the urine-cart, soon swell to a good size. After the flax and carrots the land is manured with fifteen tons of dung, which is ploughed in, and wheat sown in October. The next crop after wheat is, as usual, rye and turnips, with six tons of dung. Then oats without dung; and, after them, buckwheat also without manure. The course then begins again with a fresh trenching.—This is the usual course in the sandy loam of the Waes country. But what distinguished Mr. De Keyart's farming is his flock of ewes. Of these he has 100, who are carefully fed in the yard in summer and under cover in winter. All their food is brought to them, and as the lambs are the principal object, the ewes are well supplied with roots and corn in winter. The old crones are fatted off regularly. The manure is collected carefully: what can be washed into the tank goes there; the more solid part is mixed with earth before it is put on the land. His crops are as those of his neighbours, viz;—wheat about four to five quarters an acre, flax worth 20*l.* an acre, hemp 12*l.* In 1837 there were on the farm twenty acres of wheat, eight of flax (part with carrots and part with clover,) three of hemp, four of clover, four of oats, two of buckwheat, fifteen of rye and turnips, two of potatoes (fifty-eight acres in all.) The remainder of the sixty-five acres is pasture and homestead. The wheat is thrashed with the instrument described in page 19, and the chaff beat off is boiled in the brassin. Here we observed some small stacks of wheat neatly thatched, which might contain eight or ten loads of straw in each. The making and thatching of these is here a separate trade.

In the neighborhood of Tamise there are many small farms chiefly cultivated by the spade, which are perfect models of this species of husbandry. The farm of a man named Everat may be taken as an example. He has eight acres of land, and keeps three cows. The whole is cultivated by himself, with the help of a labourer during three months in the year, who is chiefly employed in trenching and digging. The manure is carried on the land in wheel-barrows. The land is much poorer than on the farm we noticed near Alost. The first crops after trenching are buckwheat and potatoes—the latter with all the manure that can be spared—as many as sixty tons an acre are frequently put on.—By this means the produce will be one hundred and twenty sacks, each of 200lbs. weight, or nearly twelve tons, which is a very large crop on such a soil. After potatoes he sows wheat, then rye and turnips, then flax and clover, wheat, rye, and turnips: this is the regular course, which is only varied by carrots being sown in part of the flax, so that the clover may not recur too soon on the same ground. The cows are kept in stalls with their heads completely separated from each other: each cow has her own trough, and cannot interfere with her neighbour. The partition goes back as far as behind the shoulders of the cow; when she lies down she cannot see any of the others. The food is given to them from a narrow chamber before them, in which are the troughs for the brassin, so that they may literally be said to feed like pigs. They are cleaned and curried like horses.

The habitation is neat, only one story high, containing a kitchen and two chambers, with a small garret over these. There is a small barn, cow-house for three cows, with a calf-pen. There is a place where a horse might be kept; but a horse would only be profitable if there were more land; at present his keep can be saved. The urine-tank with the privy over it is an indispensable part of every farm-yard, however small. The wheel-barrows, which are used instead of carts, have a large wheel, and the frame is light. They are calculated to carry dung and sheaves of corn. The liquid manure is carried to the field in a tub, sometimes by means of a pole between two men, or a man and a woman, sometimes on the wheel-barrow. It is poured out by means of a bowl, with a long handle, and which can take up liquid and semi-liquid substances equally well. There is an appearance of comfort in these little farms which is very pleasing. Hard work, instead of being here thought an evil or a hardship, is thought essential to the health and comfort of the individual. The children are brought up in industry. It is interwoven with all their associations; and when the young men marry, they find wives who are brought up in the same manner, and are useful helpmates to them. The great ambition of the small Flemish farmer is first of all to be able to set up his children, by giving them what is indispensable in taking a small farm. If he has been very successful, and at the same time very frugal, he will hoard his savings till he can buy a few acres of land of his own. If he can build a house, he then has arrived at the utmost point that the most sanguine man can look forward to. There are many small proprietors who have risen slowly by the labour of their own hands; and their habitations show, by their extreme neatness and the care taken of everything about them, that they feel a pride in enjoying the just reward of honest industry.—*Flemish Husbandry.*

Rohan Potatoes.

Beverly, 28th Sept. 1839.

Messrs J. Breck & Co.—Gentlemen—On the first of May last I planted thirteen hills of Rohan potatoes in my garden (or nursery,) some two, some three eyes in a hill, in all thirty-three eyes, two of which did not come up; the thirty three eyes weighed less than eight ounces; the ground is a rich loam inclining to clay, with a stiff clay subsoil, moist through the year. I manured with a good shovelfull of strong compost in each hill.

I have this day dug the potatoes from these thirteen hills, and find they weigh one hundred fifty-eight and a half pounds. The eight largest weighed thirteen, and the twenty largest, thirty pounds; the whole filled a flour barrel rounding full.

I planted some on high land, soil loose—also some on high, stiff clay soil: they did well—the poorest averaging less than twelve hills to the bushel, although in both soils they were injured by the dry weather. I am satisfied they require a moist, rich soil, and in such soil they will yield double or treble as much as any other potato I am acquainted with.

Very respectfully, your ob't serv't,

JOSIAH LOVETT, 2d.

—

Dracut, 2d Oct. 1839.

Messrs. J. Breck & Co.—As there has been so much said about the yield of the Rohan potatoes, I will send you the result of my crop from ten ounces which I bought about the first of May, and gave sixteen cents. I cut out of two small potatoes the eyes and put them into a tea cup of new milk and soaked them three days and then planted them in fifteen hills; but one of the hills was broken down, so that I had fourteen hills only, and I dug them to-day. On account of the mice getting in one of the hills, I think, I lost about two pounds, the remainder I weighed which amounted to eighty-two pounds, some of them weighing 20, 25, 28, and 32 ounces. The bearer of this saw the above. Yours, &c.

HUMPHREY WEBSTER.

Berkshire Pigs.

Mr. Editor—Sir—In a letter recently received from a gentlemen in the vicinity of Boston, I find the following advertisement, with a copy of a pictorial representation of one of my breeding sows, which requires some notice from me, to guard the public against deception:

"Berkshire Hogs.—W. S. Turner has just received 14 pigs from Albany, male and female, of the Berkshire breed. These pigs were procured of Bement & Glauson.

Framingham, June 29th, 1839."

Now, sir, as regards myself, *I deny in toto*, of having ever sold any Berkshire pigs to W. S. Turner, or any other person in that town. If Mr. Turner purchased them from me, he has some written evidence of the fact, either in a bill, certificate, or letter.

I called on Mr. Lossing, (not Glauson,) who peremptorily denies ever having sold any pigs to a person by that name.

Mr. Lossing also informed me that late in the spring or early in the summer, a person from the east called on him for Berkshire pigs; but having none except those that were engaged, inquired of him if he knew where he could find them, or some that "*resembled the Berkshire*"!!! And he "was not *very particular*—the *runts* would answer, if he could obtain them at a low price." "Dunder un blixum!" a Dutchman would exclaim, "dese tam Yanks peats de very tuyval."

Not long after this, Mr. L. was informed that a person going east with a lot of pigs and offering them for sale, exhibited a certificate with his name attached, as an inducement to purchase. This Mr. L. declares a forgery.

In another letter lately received from a gentleman near you, I am informed that "most of the drovers who pass through *******, where I keep my swine, have pigs which they call '*pure Berkshire*,' at least a few in each drove, and the *invariable* story is, that the pigs were got by your boar, out of some sow in your vicinity, by which means they injure the true breed."

Now I am not at all surprised at this, for a man living near me does not hesitate to sell half breeds for the pure blood Berkshire; and, I am sorry to say it, there are others in this vicinity, who would do the same, should an opportunity offer.

Mr. T. for aught I know, may have the pure Berkshire pigs; and had he not published that he procured them of me, I should have let it pass unnoticed; but having used my name without my authority, I deem it a duty I owe the public as well as those who have purchased of me, to make the above exposition.

Respectfully, Yours,

CALEB N. BEMENT.

Three Hills Farm, Albany, Oct. 12th, 1839.

Report on the value of Bone Manure, in comparison with ordinary Farm-Yard Manure.

BY THE HONOURABLE CAPT. W. OGILVY, AIRLIE CASTLE.

[The thanks of the Highland Agricultural Society and the honorary silver medal were voted by the directors to the author of this paper.]

Mr. Watson of Keilor, introduced the use of bone-manure into Strathmore, having seen it used in England. I am not certain in what year he began to make experiments with it, or to employ it extensively, but I remember well that the great deficiency of farm-yard dung in 1827, (consequent on the almost total failure of the crop of the previous year) first induced me to try four acres of turnip without other manure, sown with 15 bushels of bone-dust per acre, which I obtained from Mr. Watson: it cost 3s. per bushel, or £2. 5s. per acre. The crop of turnips on these four acres was at least equal to the rest raised with farm-yard manure; but as the whole of the turnips were pulled, and the land received some dung before the succeeding crop, much stress cannot be laid on the circumstance of the following white crop and grass being good.

Next year, 1828, encouraged by the former successful experiment, eight acres were sown with turnip, solely with bone-dust; the soil a light, sandy loam; the subsoil gravel and sand, coming in some places nearly to the surface, which is very irregular, but in general has a south exposure. This field had been broken up with a crop of oats in 1827, after having been depastured six years principally by sheep. The quantity of bone-dust given was 20 bushels per acre, and cost 2s. 6d, per bushel, or £2. 10s. per acre. The turnip-crop was so heavy, that, notwithstanding the very light nature of the soil, it was judged advisable to pull one-third for the feeding cattle, two drills pulled, and four left to be eaten on the ground by sheep. The following year, 1829, these eight acres were sown with barley and grass-seeds, and the produce was 57 bolls 1 bushel, or 7 bolls 1 bushel nearly, per acre, of grain, equal in quality to the best in the Dundee market, both in weight and colour. Next year, a fair crop of hay for that description of land was cut, about 150 stones an acre; and though I am now convinced that the field should rather have been depastured the first year, yet the pasture was better than it had ever been known before for the two following seasons, 1831 and 1832. It is worthy of remark, as a proof of the efficacy of the bone-manure, that in a small angle of this field, in which I had permitted a cottager to plant potatoes, well dunged, and which, after their removal, was included in one of the flakings of sheep, and had (one might have supposed) thereby had at least equal advantage with the adjacent bone dust turnip land, both the barley and grass crops were evidently inferior, and this continued to be observable until the field was again ploughed up. A very bulky crop of oats has been reaped this season, probably upwards of eight bolls per acre, but no part of it is yet thrashed.

Having detailed what may be considered a fair experiment during the whole rotation of the above eight acres, I may add, that turnip raised with bone manure, and fed off with sheep, has now become a regular part of the system on this farm; 15, 20, and, last year 25 acres were fed off, and invariably with the same favorable results, with the prospect of being able to adopt a five-shift rotation, and to continue it without injury to the land. Every person in the least acquainted with the management of a farm, of which a considerable proportion consists of light, dry sandy loam, at a distance from town-manure, must be aware of the importance of this, from knowing the expense at which such land was formerly kept in a fair state of cultivation; indeed, the prices of corn for some years past would not warrant the necessary outlay, and large tracts of land, capable of producing barley little inferior to that of Norfolk, must speedily have been converted into sheep pasture, but for the introduction of bone-manure.

Note.—For the last four years, 25 bushels of bone-dust have been given to the acre: the price this year was 3s. per bushel, or £2. 15s. per acre.

Of the Fallow.

The fallow defined.—Its effects.—Similies to elucidate the subject.—The soil mechanically retains, and chemically combines with air, water, and vegetable and animal manures.—Whence the source of fertility.—Remarks on the practical parts of the fallow process.

By fallowing, is meant a repeated mechanical moving and pulverizing of the soil, to a depth of eight, ten, twelve, or more inches, with the plough, the harrow, and the roll; and permitting, during the process, which usually occupies the spring and summer months, no vegetables to grow.

This mechanical process usually commences at a dry time in the autumn: and the land, from the consequent unevenness by the furrowing of the plough, presents a large surface to the frosts, snows, sun and weather of the succeeding winter. The effects from such an exposure, shiver the most stubborn clods, and with no cost to the husbandman.*

In the spring, the surface is harrowed and dressed down; the weeds picked off or destroyed; and the field again submitted to the plough; when the under side is turned up to the heat and moisture of the sun and showers, and to the drying winds. This exposure should be continued, if the weather be favorable and time permit, till quite dry, then to have a shower and get dry again, with the surface in the roughest state; that the effects from the alternating extremes of heat, moisture, and dryness, (the great decomposing agents of Nature), upon the largest possible surface, may the more speedily render the clods tender, the proper opportunities being taken for the operations of the harrow and roll.

Another ploughing, and perhaps dressing succeeds: then a fourth; and probably a fifth; when the duties and object of the husbandman are performed and accomplished.

A soil that has been so treated and exposed, even if very stiff in its nature, and poor when the operations were commenced, is found greatly improved in its tenderness and in its powers of fermentation, consequently in its fertility; and the benefit arising from the fallow, is in proportion to the time and labor bestowed, and the interval before a crop is again taken.

Naturally good soils need but a short period for their restoration, because they are readily brought to a pulverized state, and of course proportionally soon improved in their powers of fermentation.† Whereas the stubborn and almost barren require at least a year, or indeed better if two years are devoted to a well directed cultivation, before an equal degree of pulverization and powers of fermentation can be accomplished.

From the tendency of the fallow to render light lands close, and stiff lands light, it favors the approximation of the two different soils to the same state of fertility.

Having gone through a detail of the particulars of the mechanical part of the fallow process, its effects are the next object of attention.

The balance of affinities, or the equilibrium of the particles of matter composing the soil, are very essentially disturbed by the operations of the plough and harrow; indeed so much so that scarcely two particles, it may be said, that were in contiguity before the commencement of the ploughings, are to be found together at the conclusion of the operation; also the particles of stale air and moisture that were within the interstices of the soil at first, together with those particles in slight combinations with the soil itself, have escaped, and their places are supplied with fresh; consequently every way favoring fermentation in a high degree, as well as being rendered more easily permeable in all directions for the infant roots of future plants.‡

Now a soil, before it is broken up by the plough, is—as to its interior particles, and the air and water that may occupy the few cavities—in a comparatively quiescent state, because the various particles have entered into a chemical union with each other. That is to say, the materials of the soil are saturated with those substances they could then combine with; and therefore would so continue to remain, if the subsequent variety of the seasons did not tend in some measure to destroy the equilibrium.

A few examples may contribute to the better explanation of the above, and also materially assist future investigation. They are the following:—

What is the use of stirring or shaking two liquids when put together, or one or more liquids with one or more dissoluble solids? The object is, to facilitate a chemical union with each other, of their respective atoms which the occasional stirring effects, by removing one portion after the other of the atoms of one liquid, when they have been sufficiently long in contact to perfect a union with a portion of the atoms of the other liquid or dissoluble solid, till all the combinations of which the nature of the materials are capable of entering into under their present circumstances, have been completed.

Let a sponge, or a piece of cloth, be thrown into any dying liquid that will combine with the materials of the sponge or cloth, and there permitted to remain awhile. The first effect will be, that every pore of the sponge, &c. will be filled with the liquid, and a combination with the dye, immediately in contact with the sponge, take place when all will be again quiet. If the dye is too diluted to give the requisite colour at first, the sponge is left undisturbed, and the liquid also; for a considerable time, the shade will not be improved because a saturization has already been effected with the sponge, and the dye in its immediate contact; but if the sponge, after having remained a certain time be taken and squeezed, then returned again into the liquid, it will absorb a fresh quantity of the dye by fresh particles being exposed to its surface, when a second coat will be formed; and so on with a third and a fourth, at every alternate immersion and squeezing, till the requisite shade be accomplished. In this manner any degree of shade of a dye may be communicated to a piece of cloth, or other material capable of taking it up, in a much shorter time than in any other way.

Again, how does Nature effect the oxidation of the blood in the lungs of animals? It is upon the same simple principle: for what does she do to gain this important end? Let us for a moment observe ourselves in this instance; we inhale a quantity of air into our lungs, and then immediately after exhale another quantity; a moment's pause ensues, when the process is repeated again and again, to the end of our existence. Now the lungs are a body somewhat like a sponge, but composed of an infinite number of ramified tubes, by which means an immense surface is exposed to the air.

The air that is inhaled is the amospheric, which is composed chiefly of nitrogen and oxygen. The air exhaled is different, being partly nitrogen, partly carbonic acid gas, with water in a gaseous form. We see, then, that the carbonic acid gas has been substituted for the oxygen, and if respiration be suspended, the air, just fresh received into the lungs, cannot yield up more than its quantity of oxygen, if continued within them for the space of an hour; and thus a balance, or equilibrium would be established; consequently, to gain more of the oxygen, the stale air must be expelled to admit its place being occupied by a fresh quantity of atmospheric air. This is effectually done by the moment's pause after exhalation, as the pause admits of the expired air escaping and ascending out of the way, having been rarified by heat, and rendered lighter than the atmosphere, and thus making a pure entrance for the inhaled air.

Another simile, and a familiar one, may also be brought forward. It is of a fire that wants stirring, which exactly resembles a piece of land permitted to remain awhile unmoved. For the fire is becoming stale, or a balance of affinities is forming, or, properly speaking, the surfaces of the fuel, immediately in contact with the air, formed a combination with the air whilst the heat was sufficiently strong to effect it; but by the hollowness consequent on combustion, from the consumption of a portion of the fuel, the particles in a state of ignition become more and more distant, when the heat proportionally declines, till falling below the power of decomposing the air, which now only gets rarefied in its passage through the embers, and thus robs them of their remaining heat, when the fire soon goes out. If, however, it be stirred in due time, and with judgment, whilst the heat is sufficiently powerful to decompose the air, a large exposure of fresh, or unsaturized surfaces and particles are presented to the current of fresh air, together with the approximation of the parts in combustion which, by consolidating the heat that was before distantly divided, materially prevents the further loss of the same, and consequently favors immediate ignition. The fuel being put closer together, is however, left sufficiently porous for the free circulation of the air, which accordingly enters into chemical union with those particles that are capable of receiving it; when the oxygen of the air, from a gaseous form, assumes a more condensed one with the fuel, the latent heat is in consequence given out, and shows itself in the general redness; should hydrogen be present, as in coal or wood, it unites with this gas, and becomes cheeringly visible in the flame.

To further elucidate this meaning respecting this balance of affinities, and the advantage gained by moving the soil, the reader is requested to inspect a dung mixhill that has been made two or three months. This mixhill will be found, if trodden down hard by the horses and carts during the time of making, or the interior defended from the outward air by a covering of earth, in a comparative quiescent state; and why? Because the fermentation has gone as far as the fresh air contained within lasted, when the balance of affinities takes place. Now let this heap of manure be turned regularly over, and each spit broken and shaken in pieces, after the manner of making a cucumber bed, and spread about to prevent the same two pieces that were together before, from coming in contact again; the uncombined stale and gaseous moisture will then be facilitated in their escape; and from having less affinity for the materials of the manure than the fresh air and gaseous moisture to which the materials are now exposed, will readily give place to them, when a fresh and strong fermentation ensues; and this arrives at a great height after some hours, or a few days, and so continues, till the fresh store of air or moisture, and the new position of the particles of the manure are exhausted and saturated, when all is quiet again.

When a soil is broken up by the plough and highly pulverized, this essential effect, fermentation, is gained which cannot take place without the presence and consequent decomposition of air or water, or both. This being the case, these two questions necessarily arise. The first; is air always present in the soil? The answer is, that it is; because it is impossible that a pulverized and porous body, such as the soil, which is always exposed, can maintain a vacuum in its innumerable cavities. The next respects the presence more or less of water in the soil. The same answer is again given, that it is present. The rains are the occasional contributors, together with the dews; and the constant interchange of the air, charged with moisture, ascending and descending through the upper part at least of the pulverized soil, by the influence of the interior fermentation, the day's heat, and the night's chill, leaves behind in this climate, a quantity sufficiently great to keep the soil moist even in the driest seasons.

Of the two former there is a positive certainty: and of the latter, the ploughman's experience equally satisfies him of this fact; but it is not discoverable in unmoved land, which is in consequence generally hard, dry, and cracky, during the summer months.

The next step to be taken in this inquiry is, to ascertain whether the soil, by cultivation, will mechanically retain, and chemically, or by cohesive attraction, as Sir H. Davy says, combine with air and water, and any gaseous materials.

What has been shown already relative to the porous nature of the cultivated soil, equally answers in this case. For having proved that the air is more or less present and diffused through the soil in proportion to its improved state; then this presence of the air denotes also its mechanical retainment.

The next investigation relates to the capability of the various soils chemically combining with air and its component parts, and the products of decomposed vegetables and animal manures, beginning with the latter.

When vegetable and animal manures are applied to the soil and buried by the plough, they undergo fermentation, and gases of various natures are evolved; these, passing into the finely pulverized earth, become arrested in their nascent state by the numerous particles of the same, and are so strongly retained, as to exhibit their presence for a series of years afterwards (although every part of the manure appears gone), by the superior crops that follow, and which gradually consume them. If these gases were incapable of chemical union, then from their specific gravity being so far inferior to that of the soil, they must effect their escape in a greater or less degree, but more particularly so at every successive ploughing; consequently with the proportioned impoverishment of the land according to the frequency of the operation. However a long age of experience has no proof of such results; therefore the detainment of the several gases for such a period must be more than mechanical, consequently then, is chemical.* The like reasoning applies to atmospheric air.

The presence, or mechanical suspension of water in soils, has been before shown; and its chemical or cohesive combination with the particles of the earth, is on the same principle as water with lime; though the union is not so strong; but the strength of the union, and the affinity of the soil for water, are increased by cultivation.†

---

* If it were practicable to expose land to the effects of the winter season, more than is generally done, by one or two extra ploughings during that period, the advantage gained in fertility would be considerable. But, the fear of kneading the land whilst wet, and the impossibility when frosty, sets all attempts on any large scale at defiance. In a garden, a bed may be dug and re-dug during slight frosts, and thus fresh surfaces and clods turned up to the weather, when the great benefit of the winter's exposure and pulverization can be obtained; and indeed is so by industrious gardeners.

† Fermentation is the struggling of different affinities of materials in contact with each other, to enable their respective proportions to continue at rest: or the struggling of various particles of matter for the balance of affinities. It is one of the chief objects of a well directed cultivation to continue this fermentation, having the seasons and the power of vegetation to assist, lest vegetation should be exposed to a too long continuance of the balance of affinities.

Land dries much sooner when moved, than when left untouched. Just harrowing the surface dries the soil rapidly, the weather being fine; and why is this? It is because the water and air in the unmoved soil is in a comparative state of rest or balance; and having the same surface exposed to the sun and winds for some time, they at length saturate the particles of the soil exposed to their influence, consequently at last excite little fermentation: when, however, the surface and clods are disturbed by the harrow or plough, every part is fresh to both sun and air, fermentation becomes strong (proved by a thermometer) and dryness rapidly ensues.

‡ A gardener, whilst digging, always takes care to break each spit in pieces, both on the top and in the trench. He does this, knowing from experience that this extra labor will be amply compensated for, by the proportioned superior produce of the next crop.

* This is a strong practical fact, that the particles of the soil have a superior affinity for the component materials of animal and vegetable substances than the atmosphere; if true, the soil never can be so injured by exposure as some persons have imagined: indeed facts are every way in favor of exposure, so much so that it is absolutely necessary from the essential benefit the land derives by being allowed to breathe, to exchange its stale bad materials for those that are fresh and good.

Meat, as of a dead sheep or horse, is sweetened and made tender by being buried in the ground for a day or so; for the soil commences a digestive process, and imbibes and retains all the putrid effluvia as it generates. Dogs are, by their instinct, aware of this when they bury a bone, otherwise, from the acute smell of their own species in general, their store would be easily discovered, if the least effluvia escaped during that time, and the treasure robbed; but the occurrence is very rare.

† A portion of soil being taken from a cultivated fallow, and compared with an equal quantity from an exhausted soil close by, and with corn in ear growing upon it, the differences were; that the fallow soil retained moisture longer than the exhausted soil, and when both were equally dried, the former regained moisture from the air quicker than the latter—a most important fact. Again; a thermometer was inserted three inches into a soil cultivated a few hours before, and then put the same depth into the same soil close by, which had not been so recently moved; the result proved

When there is an excess of water after saturization, it evaporates in dry weather, and forms a mud, when very wet.

Before terminating this part of the inquiry, the following well known fact is adduced in support of the argument; that aration alone is capable of fertilizing land. Whence is the source of such fertility? We know of none; if we exclude the air and water, and the improved digestive powers of the soil, saving the pulverization; which, indeed, without these would be next to nothing; therefore these three must be pronounced as the real source, which, under the influence of the sun and seasons, yield to the hand of industry their hidden treasures, and fixes them in the soil, to be gradually taken up by the future vegetation.

This satisfactory conclusion may at length be drawn, that the particles composing a well managed soil are capable of mechanically retaining and chemically combining with air and water, and their principles; and also with the various products from vegetable and animal manures. And this capability of the soil is to be improved, strengthened, and perpetuated, by well-directed cultivation; thus proving not only the use, but the necessity and importance of cultivation.

To dismiss this interesting chapter without a few remarks on the practical parts of the fallow process would be incorrect, and to do so it is necessary to review some of the operations, and make comments as we proceed.

The commencing the operation for the fallow in the dry part of the autumn is highly necessary, and the advantages are these: that the plough presents an entire fresh and somewhat dry surface to the influence of the succeeding winter, instead of the same which had been before long exposed during the preceding summer, and was in consequence become stale, therefore the soil would not derive the proportion of benefit it ought to do from the ensuing winter's frosts, rains, and other changes, which however will be gained by the particles of the now fresh turned up surface. Again, the land being broken up as dry as it will plough, and never mind how rough, the surface not only presents a greater number of particles to immediate exposure, but being at the same time rather dry than otherwise, the winter's fresh rain and snow enter more readily and generally into every part of the clods, and after the manner of lime, crumbles the same to powder. Whereas if the same land be ploughed up wet so as to knead by the horses, the cavities of the soil, from this cause, being already filled with water, like the sponge, can receive no more, and therefore from the approaching winter there is no chance of it to be again moved or become dry. The fresh rains and snows which may fall, cannot penetrate through the clods, every interstice being already pre-occupied by the former moisture; and this same quantity thus locked up, as the liquid dye in the sponge or cloth, and the air in the lungs, when it has parted to the soil all that it is capable, the balance of affinities is established by the saturation; and no further benefit is to be expected, except upon the mere surface, where the frosts and sun may occasion a dryness. Such land, when ploughed in the spring, will, as the expression is, cut up whole furrow, instead of being in the fine and tender state of the land that was ploughed dry, and now again ploughed in a dry time also.*

With respect to the burying all the stubble and weeds; these should always be done when practicable, and if done, they will, during the exposure of the winter season, particularly in very wet and stiff land, keep the same open and porous, and thus, not only make it more easily divisible by being blended with the soil, but assist the running off of any superfluous water by the hollowness which the stubble naturally occasions, at the same time admitting a circulation of the air; besides, whatever of the stubble and weeds goes to decay, fertilizes, lightens, and improves, at no expense.

If a person follows the plough in the spring whilst stirring that land which was ploughed in the autumn, where the stubble and weeds were buried, he will see that the land, in turning over, separates readily into pieces where the stubble is intermixed, and thus materially assists in the commencement of its pulverization. This stubble, on examination, will be found in a blackened and mouldy state, like manure, with the green weeds quite decayed, excepting the hearts of some of those plants that are of the biennial and perennial kinds; all this proceeding from the fermentation which ensued during the changes of winter, aided by the easy decomposable nature of the substance buried, and taking place too at a period when vegetation is at the weakest; in consequence, the decay of the weeds, rather than their vegetation, followed, to the greater benefit of the land. Whereas, if the weeds had been suffered to remain unmolested all the while, they would, at least, continue alive, and if a mild winter, have grown.

The advocates for not ploughing in the autumn, say, in their defence, that such lands plough up more tender and dry in the spring. Let this be granted, because they may argue, that the under soil, not having been disturbed by the plough, becomes porous as the roots of the former plants decay, as well as retaining uninterrupted the old water-courses and cracks, which were formed the preceding summer, and thus let off the winter's rains and snows; also, the old heaten down surface arrests a part of the water which is then dissipated by the sun and winds that follow. In answer it must be observed, the object of the husbandman is not only dryness, but an improved fertility by the winter's exposure, and which cannot take place in an unmoved soil, according to what has been already stated, and likewise, because the channels and cracks, similar to a fire, become hollow, and want stirring; having had the particles of the earth lining their surfaces so long exposed to the summer's rain and air, they thus become effectually saturated as far as they were capable of receiving, and in consequence, little or no after benefit can be gained from the succeeding winter's rain and snow. Such reasoning as the non-autumnal ploughers use, only applies, if with any force, against those farmers who are in the habit of ploughing up their land at that season of the year when really too wet.*

The spring tillage for the fallow comes next; but before entering upon particulars it may be asked, which of the four seasons are those hest calculated to crown our operations with the greatest success? The spring and early part of the summer are decidedly to be preferred, the land having of course been previously rough ploughed up in the autumn. This opinion is thus defended.

In the first place, let this question be put, when is vegetation the strongest? Why, certainly during the spring and early summer months; then of course must be the time of the greatest chemical changes with the soil, air and water; therefore, the more the land is exposed to the influence of the sun, air, and rain, by cultivation at this important time, the greater will be the increase of fertilization.

To account for all this is the next question, and it is thus attempted. That contrasts and extremes, acting alternately on matter, produce in general the greatest effects, by weakening and destroying the balance of their affinities; as is instanced in the familiar case of hot water breaking a glass that is cold, and cold water breaking a glass that is hot. But the continuance of such contrasts for any length of time in either extreme, preserves the equilibrium of their particles unaltered,† as for example, paper when dry, and the piles of bridges that are always wet. What have we then so favorable to the overthrow of the chemical affinities of the soil? A winter, the very extreme in its nature to the preceding summer, as being a period overcharged with moisture and cold, in opposition to its dryness and heat. As these extremes of wet and cold continue for about six months, the very active energies of vegetation, and of composition and decomposition, are not to be wondered at, when the opposites, heat and dryness,‡ are increasing in their powers in the spring and early summer months, till the sun has reached its greatest height and limit.—The rays of the sun afterwards, being on the decline, become daily less and less powerful, therefore less and less effect must be produced, and this explains the cause why the vigour of vegetation is then seen to cease,§ and with it we naturally infer, the fertilizing effects, as respects composition and decomposition on the soil also, with the consequent tendency at the same time to a rest in their several affinities; though afterwards the autumn rains come, and vegetation is seen to revive a little, yet winter soon follows, and seals up all with its frosts.

OF THE SPRING TILLAGE.

Should the land be extremely foul, harrowings and scarifyings,* with pickings and burnings, must be had recourse to whilst the land is in the driest state, and all completed, if possible, before the next ploughing. The plough may then be introduced and let into the land the greatest depth required, that the largest possible mass of soil may gain the benefit of the future exposure and tillage. With a field fairly clean the ploughing may at once commence, as the surface will be quite tender, and sufficiently pulverized without the aid of the harrows.

If the fallow is to be manured, no better time can be chosen than the present to be now ploughed in—but more of this hereafter.

During the early spring tillage, be careful to knead the land as little as can be avoided, and, as the season advances, it is best not to suffer a horse's foot or a cart-wheel on the surface until the soil beneath is too dry to knead;† because all the former labor will be in a great measure lost, whilst the time is too short to do it over again. Nevertheless, should necessity oblige a husbandman to plough his land before it is fit, as he is to expect extremes of dry weather instead of the winter's rain, the clods may get perfectly dry, and the spring showers falling afterwards would re-pulverize them.—The main object is to let the clods be quite dry, when, if rain does not fall, they, being returned to the bottom of the furrow by the next ploughing, will gain sufficient moisture to dissolve and pulverize them. In fact, the plan of always ploughing in, when possible, a dry, dusty surface, instead of a wet one, is to be preferred, because the extremes of dryness of the former surface being turned to the bottom of the furrow, where there is always moisture, which being absorbed in an equal degree by the dry soil occasions a rise of temperature readily detected by a thermometer, consequent on the union with the moist earth and with the air contained within the interstices of the clods. But when the top surface is ploughed in wet, little or no interchange can take place, for the reasons before adduced.

(Remainder in our next.)

---

that the fresh moved soil raised the quicksilver at least 2° higher than the unmoved, and selecting a spot just manured and fresh moved, the difference of temperature was found greater.

Cultivation increases the powers of decomposition and composition of the soil, or fermentation, denoted by the proportioned increase of the growth of plants; likewise by the more rapid decay of any vegetable or animal substances contained therein. But vegetables growing in a soil have the tendency to lower the temperature of the same, caused, it is conceived, partly by their shade, and partly by their very act of growing, which by transforming the more solid and liquid manures about their roots into a rarer or gaseous form, occasions the difference, from the consequent consumption of a portion of the surrounding heat taken up in a latent form during the rarefaction of any of the above substances.

It is also known, that fish-manure ploughed in early for a fallow, last longer than when ploughed in for a crop on an exhausted season. Thus proving again that cultivation strengthens the chemical powers of the soil. On the same principle farm-yard manuro will go further when put on a fallow.

* The best remedy, when the season and time obliges the land to be ploughed wet, is to plough the furrows up an hedge as much as possible, that the water may drain away the easier, with a greater surface being thus left for the frosts, sun, air, &c, to operate upon. Land should never be ploughed flat when in a wet and kneady state.

* Land improves very slowly indeed when suffered to lie unmoved; if otherwise, the not cultivating of it would of course be the cheapest plan; but facts are the reverse, and the cause easily explained. Although the unmoved land receives the effects of the same sun, the same rain and winds, yet little fertility is left behind, because the surface particles are early saturated, when whatever comes afterwards is lost to them. No extra heat and chemical powers are communicated to the soil by cultivation, no change of position of the particles of the soil relative to each other takes place, and from being deficient of these essentials, no extra fermentation can ensue, consequently, its improvement in fertility must be proportionally small; and this is borne out by facts. Therefore, every omittance of cultivation, if a gain in labor, is a loss in fertility.

† The preservation of fish and meat preserved in ice is the result of the strong balance of affinities.

Meat preserved in salt, fruit preserved in close stopped jars and bottles, are instances of the same kind.

‡ That is to say, though more rain is said to fall in summer than in winter, yet it quickly vanishes again, and by its evaporation assists, no doubt, in the decomposition.

§ Upon the same principle may be explained the cause why the morning sun has more effect upon vegetation than the afternoon.

* Scarifying is very well for cleaning land, but never will answer as a substitute for the plough; because, a scarifier is unable to bring up and turn over the fresh soil of the bottom to the top for exposure, like the plough: consequently, the top surface soon getting saturated, gains no more benefit from the sun, air, and rain, however often the same surface may be moved.

On following the plough, whilst preparing a bean land for wheat, much of the stubble of the barley crop ploughed in for beans was observed undecayed, although the last crop, beans, being a drilled one, was horse-hoed at least threo times. Proving, that the effects of superficial cultivation do not descend with much influence below the actual operation; also proving, that the lower materials of the soil must be actually moved, and brought up to the sun. air, &c. before the requisite strong fermentation and benefit can ensue.

† A clayey soil when rammed quite close for the bottom of a pond, will remain in a perfect state of the balance of affinities for more than a century; for if it did not, it would soon lose its property of holding water. Now land of a clayey nature in a field will be affected similar to the clay at the bottom of a pond, if trampled on by horses in a kneady state; and the evil will be proportional to the purity of the clay.—If it is full of manure and foreign substances, the kneading will go off in time, by their fermentation. Pond makers are aware of this fact; and therefore carefully eject all vegetable and decomposable substances from their clay before ramming it down, knowing that they will be the means of destroying all their present labors, by breaking down the texture of the clay, and thus cause the pond to leak after a few months or years.

Young Men's Department.

Chemical Catechism—Chapter IX.

[*From Parkes' Chemical Catechism.*]

OF SIMPLE COMBUSTIBLES—*continued.*

What is the substance you call carbon?

The base of common charcoal, divested of all impurities, is known to chemists by the name of CARBON.

What is the most striking property of pure carbon.

Carbon is capable of crystallization, though not by art; and in that state it is called diamond.(1)

(1.) The diamond is chiefly found near Golconda in Asia, and in Brazil. It always occurs crystallized; indeed, if not, it would be carbon and not diamond. See a note respecting the diamond under the article Steel, in the chapter on Metals; where you havo an additional proof that diamond is simple carbon. It is wonderful that Newton, who had no chemical means of examining the diamond, should have conceived the idea of its inflammable nature. See Additional Notes, No. 35.

Mr. Tennant has satisfactorily shown that tho diamond is pure carbon, carbon crystallized. See *Philosophical Transactions* for 1797. The diamond is the hardest substance in nature, and one of its rarest productions. From its hardness it is employed for sawing and boring the hardest stones. It is a conductor of electricity, though charcoal is a non-conductor of that subtile fluid. "Diamonds are usually found in an ochreous yellow earth, under rock of grit-stone; they are likewise found detached in torrents, which have carried them from their beds. The sovereigns of India reserve the largest, in order that the price of this article may not fall. Diamonds have no brilliancy when dug out of the earth, but are covered with an earthy crust. Diamonds are also found in considerable numbers in the island of Borneo. Whenever the mines are searched for them, an overseer attends, and watches

What are the other properties of carbon?

Carbon has the property of de-oxidizing the oxides of metals and other combustible substances (2), and with this view it is often used in the arts. These purposes are effected by means of fire, the carbon uniting to the oxygen to form carbonic oxide, or carbon acid (3); and the metal thus deprived of oxygen, is left in its pure state.

Does carbon enter into any other combination?

Carbon is found in large proportions in bitumen, petroleum, and pit-coal; it seems to be ready formed also in all vegetables, and in most animal substances; and combined with oxygen, enters into the composition of a great variety of the products of the mineral kingdom.

What is the proportion of carbon in pit-coal?

Pit-coal vary in quality, according to the different proportions of carbon and bitumen which they contain (4); but carbon is the *chief* ingredient in all. What are called *slaty* coals hold also from 10 to 40 per cent. of earth (5); and some coals likewise contain a considerable quantity of the sulphuret of iron, known by the name of *martial pyrites*.

What is the use of carbon in the vegetable kingdom!

Carbon is not only a component part, but it forms nearly the whole of the solid basis of all vegetables, from the most delicate flower in the garden to the huge oak of the forest(6).

If carbon forms so large a part of all vegetables, what occasions that infinite variety which we observe in the vegetable creation?

We are in a great measure strangers to the economy of vegetables; but much of this variety may be attributed to the different modifications of carbon(7), as well as of the other principles which enter into their constitution(8).

What products of vegetation are there which are indebted to carbon for their formation?

Carbon not only constitutes the base of the woody fibre, but is a component part of sugar, and of all kinds of wax, oils, gums, and resins; and of these again how indefinite is the variety!

How are these substances formed by the vegetating organs of plants?

All living vegetables have the power of decomposing water(9), and of combining in different proportions the hydrogen of the water with the carbon of the soil, as well as with that of the carbonic(10) acid of the atmosphere(11), to form the numberless productions of vegetable nature(12).

If carbon and hydrogen enter into the composition of all these substances, how is it that one vegetable affords gum, another resin, another oil, &c.?

The infinite variety which there must be in the internal organization of vegetables, to enable different orders to prepare such different substances from the same elements, renders this subject too intricate and minute for our investigation. We feel the insufficiency of our faculties—"The will of God is the ultimatum of all human knowledge."

Is it known what other substances are employed by nature for the formation and growth of vegetables?

All orders of vegetables are produced from four or five natural substances, viz. caloric, light, water, air, and carbon(13). Nature has required only these in order to form even the most exquisite of her productions—

"With hues on hues expression cannot paint,
The breath of Nature, and her endless bloom."

How is it that such an inexhaustible variety of forms, colours, tints, odours, tastes, qualities, &c. so conspicuous in this kingdom of Nature, can be produced from such a scanty number of natural substances?

The means by which all this is effected are unknown to us: but this we know, that "these wonderful harmonies are not by necessity in the nature of the elements, but in the will of Him who has ordained them, in subordination to the wants and the enjoyments of his numerous creatures(14)."

What is the office of carbon in the animal *kingdom?*

As carbon is a necessary part of sugar, of oils, &c. it consequently enters into the composition of animal milk, and of animal oils and fat; it is also found in albumen, gelatine, fibrina, and in many of the animal secretions.

Does carbon enter into any mineral combinations?

It is imagined that most of the metals may be combined with carbon: but at present we know only of its combination with iron.

---

the workmen with great care, that the largest may be secured for the sovereign prince. Notwithstanding, they are frequently conveyed away clandestinely by the workman, who will swallow them." Von Wurmb's *History of Bornea.*

The usual method of calculating the value of diamonds, is by squaring the number of carats, and then multiplying the amount by the price of a single carat: thus, supposing one carat to be worth £2. a diamond of 8 carats is worth £128 being 8 x 8 x 2. A carat is four grains. *Polished* diamonds, without blemish, are worth about £6 per carat.

In the year 1772, the empress of Russia purchased a diamond that weighed 779 carats, nearly 6½ ounces troy. She paid the immense sum of twelve tons of gold for it, and granted a pension of 4,000 roubles per annum to the vender.

(2.) Charcoal has such a powerful affinity with oxygen, that in a proper degree of heat it will abstract it from all other substances.

(3.) The merit of the discovery of carbonic acid is due to the illustrious Dr. Black of Edinburgh. Those who have not been in the habit of reading the early chemical writers can have no idea of the service which this great man has rendered the science by his very accurate investigation of this compound gaseous substance.

(4.) The immense quantity of pit-coal which is deposited beneath the surface of the earth is truly astonishing, and affords abundant matter for reflection. This kind of fuel is consuming day after day in incalculable quantities; and so great is the store, that there is no probability of its being exhausted for ages yet to come. Supposing the formation of pit-coal to be owing to the deposition of vegetable and marine animal matter; the same process must be still going on, and the inmost recesses of the present seas may be receiving the materials of fuel for the inhabitants of new continents in the most remote periods of the world. The wise economy of the great Author of Nature, in this constant circulation of the elements of matter, is equalled by nothing but his own infinite beneficence:

"Who, not content
By one exertion of creative power
His goodness to reveal; through every age,
Through every moment up the tract of time
Adjusts, accommodates, and blesses all."

(5.) There are four species of coal, very distinct from each other: the *graphite* of Werner, or plumbago; the *anthracolite*, the *jet*, or pitch coal: and the common coal.

One hundred parts of plumbago contain, according to Berthollet, about 90 per cent. of charcoal and 10 of iron. That of the best quality, and which is found at Keswick in Cumberland, is used in making pencils. Plumbago has also been found lately in considerable quantities in an estate about 7 or 8 miles north of the town of Ayr in Scotland, and in some parts of that neighborhood it even occurs at the surface of the ground.

Anthracolite, or anthracite, is distinguished from other coal by burning without flame. It is composed of 64 charcoal, 33 silica, and 3 parts of iron.

Jet occurs in Scotland, at Whitby in Yorkshire, in Bavaria, &c. and in France near the Pyrenees. At the latter place more than a thousand men, it is said, are constantly employed in fabricating it into ornaments of dress, drinking vessels, rosaries, &c. It is composed of bitumen and charcoal: 76 parts charcoal, 22 parts bitumen, and 2 parts earth.

Common coal is composed of bitumen and charcoal in different proportions, according to its quality, and the places whence it is procured. At Newcastle-upon-Tyne, martial pyrites are often found mixed with the coal, in such abundance as would render the coal unsaleable; but persons are employed to pick out these pyrites and remove them to a proper situation, where in process of time they become acidified, and fit for the production of green vitriol. See an account of this process in Chapter X. under the article Salts of Iron. This species of coal, when, in contact with water, is apt to be decomposed, and to burn spontaneously. Ships at sea have sometimes been suspected to have been lost by this means. His Majesty's ship Ajax, of 74 guns, took fire a few years ago in the middle of the night on a station in the Mediterranean, and no cause for that dreadful catastrophe has yet been assigned.

(6.) It has been discovered that air which has been spoiled by the breathing of animals is peculiarly fitted for the vegetation of plants; and no doubt this is owing to its containing a larger portion of carbonic acid. By the analysis of soils it has been proved, that of all the substances found in the mixture of earths which constitute a soil, calcareous earth contributes most certainly to its fertilization. An interesting account of some experiments on manures, by Mr. Arthur Young, may be seen in the *Retrospect of Philosophical and Chemical Discoveries*, vol. i. page 118. There is an ingenious memoir by Dr. Paris on the application of mineral manure to land, and on the connexion which subsists between the geological structure of any particular district and its agricultural economy, in the 1st volume of the *Trans. of the Roy. Geol. Society of Cornwall*, pages 168—200.

(7.) Vegetables have the power to absorb oxygen from the atmosphere, and to transmit it to the absorbent vessels of the roots. It cannot be questioned but that this oxygen becomes useful in vegetation, by converting the carbon of manures into carbonic acid. See Additional Notes, No. 48.

The operation of paring and burning turf, which is always found by farmers extremely serviceable to their lands, is doubtless rendered universally advantageous from the carbonaceous matter, which is produced by the burning.

(8.) When we consider the small number of simple substances which enter into the composition of plants, how astonishing is the variety that has been given us by the profuse hand of Nature! The species of vegetables already known are more than 40,000, and large additions are daily making to this number by new discoveries. Is it possible that so bountiful a provision can have been made by Nature ultimately for the use of man?—Yes "for him she has covered the earth with plants; and though their species be infinite in number, there is not one but may be converted to his use. She has selected some out of every class to minister to his pleasures, or his support, wherever he shall please to fix his habitation. Others serve for his bed, for his roof, for his clothing, for the cure of his diseases, and for the fire of his hearth."—St. Pierre's *Studies of Nature*.

Fourcroy has remarked that "vegetables may be considered as beings intended by nature to *begin* the organization of crude matter, and to dispose the primitive materials of the earth and atmosphere in order to become the source of life, and consequently to establish a communication between minerals and animals; from whence it follows, that plants are truly chemical apparatus employed by nature to produce combinations which would not take place without them.—Fourcroy's *System of Chemistry*.—Nature is as admirable in the simplicity of her means, as in the constancy and regularity of her operations.

(9.) When we decompose water, we can do it only by abstracting its oxygen and liberating the hydrogen, which is easily effected by some combustible bodies. But vegetables perform this process in a different way: they preserve the hydrogen and set the oxygen free. This process of Nature in the latter instance, has been noticed in a former chapter.

Berthollot has remarked that the decomposition of water must always take place to give rise to substances of a resinous character, when the vegetation is performed without the concurrence of foreign bodies. See his *Essay on Chemical Statics*, vol. ii. page 393.

(10.) Van Helmont planted a willow, weighing fifty pounds, in a certain quantity of earth, covered carefully with sheet lead: he kept it in this state for five years, watering it with distilled water; and at the end of that time the tree weighed 169 pounds three ounces: the earth in which it had vegetated being weighed at the same time, was found to have lost only three ounces. This was repeated by Mr. Boyle with a similar result.

(11.) Organized beings cannot live upon the matter in which they vegetate: Nature, therefore, by making the air their food, has afforded them nourishment, without offering violence to their tender organs.

(12.) Sennebier found that plants watered by water impregnated with fixed air grew more luxuriantly than plants watered as usual; and that when insulated from every substance which could afford it to them immediately, they acquired carbon by the decomposition of carbonic acid gas in the atmosphere. This they take in by the under surface of their leaves, as well as by their roots.

It appears from hence, that it is not requisite to the growth of vegetables that matter should be presented to them in the solid form, but that they owe their increase chiefly to the decomposition of water and carbonic acid.

(13.) It has been shown that water and atmospheric air are the natural food of plants. Caloric is necessary to enable vegetables to decompose water and air; and light is equally requisite to give a part of the oxygen of these substances a gaseous form, and to put it in a proper state to be thrown off by the leaves. The other portion of oxygen goes to the formation of sugar and the vegetable acids. The analysis of vegetables confirms this theory; for, however they may be examined, the result is always the production of oxygen, hydrogen, and carbon. Some plants yield also a portion of silica, and others lime; but these no doubt are taken up by the roots from the soil. See Sir Humphrey Davy's paper on the silica found in the epidermis of reeds, &c. in Nicholson's *Journal of Philosophy*, &c. for May, 1799.

When we consider that the many thousand tribes of vegetables are not only all formed from a few simple substances, but that they all enjoy the same sun, vegetate in the same medium, and are supplied with the same nutriment, we cannot but be struck with the rich economy of Nature, and are almost induced to doubt the evidence of those senses with which the God of Nature has furnished us. That it should be possible so to modify and intermingle a few simple substances, and thence produce all the variety of form, colour, odour, &c. which is observable in the different families of vegetables, is a phenomenon too astonishing for our comprehension. Nothing short of Omnipotence could have provided such a paradise for man.

"Soft roll your incense, herbs, and fruits, and flowers,
In mingled clouds to Him, whose sun exalts,
Whose breath perfumes you, and whose pencil paints."

(14.) The various orders of vegetables provided in every part of the globe for the countless forms of animated existence, are eminently illustrative of the provident care of the Creator, and show us how great and how good is the Father of the families of the whole earth. The following passage from St. Pierre's *Studies of Nature* is so well calculated to impress this truth, that it is unnecessary to apologize for its introduction:—"The sluggish cow pastures in the cavity of the valley; the bounding sheep on the declivity of the hill; the scrambling goat browses among the shrubs of the rock; the duck feeds on the water-plants of the river; the hen, with attentive eye, picks up every grain that is scattered and lost in the field; the pigeon, of rapid wing, collects a similar tribute from the refuse of the grove; and the frugal bee turns to account even the small dust on the flower.—There is no corner of the earth where the whole vegetable crop may not be reaped. Those plants which are rejected by one are a delicacy to another, and even among the finny tribes contribute to their fatness. The hog devours the horse-tail and hen-bane: the goat, the thistle and the hemlock.—All return in the evening to the habitation of man, with murmurs, with bleatings, with cries of joy, bringing back to him the delicious tributes of innumerable plants, transformed, by a process the most inconceivable, into honey, milk, butter, eggs, and cream."

Prospectus of the Cultivator, Vol. VII.

A CONSOLIDATION OF

Buel's "Cultivator" and the "Genesee Farmer."

WILLIS GAYLORD AND LUTHER TUCKER, Editors.

JESSE BUEL & Co. Proprietors.

THE first number will be issued in January, 1840, at which time all existing subscriptions will terminate, and the paper will be discontined, unless the subscriptions shall have been or are renewed. The price, as heretofore. will be *One Dollar* a year, payable in advance. Postmasters, agents and others, who will obtain subscribers, and transmit the subscription moneys free of charge, will be allowed commissions at the following rates:

For ten subscribers or over, - - - -	10	per cent.
twenty or over, - - - - - - -	15	"
fifty or over, - - - - - - - -	20	"
one hundred or over, - - - - -	25	"

On ten or more copies for schools, or agricultural premiums, a discount will be made of 33 per cent.

It has been decided by the Postmaster-General, that postmasters have the right to enclose money to the publishers of newspapers, for third persons. This liberal construction of the post-office law, we hope, will induce postmasters to take an interest in the circulation of the Cultivator, which we may assume, without vanity, will tend to improve agriculture wherever it circulates, and consequently to benefit the neighborhood.

The publication of the Cultivator was commenced at 25 cents per volume; the price was afterwards advanced to 50 cents, and at the commencement of the fifth volume, to one dollar per annum. It is due to our patrons and ourselves to explain the cause of this increase in price. The size of our pages has been enlarged, the quantity of matter increased, and the quality of the paper improved, until the expense of type-setting and paper, the two prominent items of our expense, is now more than double what it was when the price was fifty cents, and four times as great as it was when the price was but twenty-five cents. To enable the reader to judge of its now relative cheapness, compared with literary periodicals, we state for their information, that a volume of the Cultivator, including its usual extra sheet, contains about double the quantity of matter that is contained in two volumes (published in a year) of the North American Review. The subscription price of the two volumes of the Review is five dollars—that of the Cultivator one dollar. To be equal, in proportion to the quantity of matter, the price of the Cultivator should be ten dollars a year.

We are enabled only to print the Cultivator at this small price, from the extent of our subscriptions; and we are indebted for our liberal subscription to the kind offices of our correspondents and agents. To these we tender again our hearty thanks, and respectfully invite a continuance of their favors, both in behalf of the publishers and their patrons.

No papers will be forwarded to any subscriber, unless paid in advance, either to the proprietors, or to their authorized agents.

Should any gentleman to whom the Prospectus may be sent lack leisure to present it to his neighbors, he will do us a favor, and we think a public service, by placing it in the hands of some one who will take an interest in soliciting subscriptions.

☞ Agents will please number the subscribers whose names they send us, from one onwards, the more readily to determine the total, and to assist in keeping accounts correct.

To meet the public demands, we have published a new edition of our four first volumes, which may be had, stitched, at 50 cents per volume, and also in different forms of binding, with the addition of the binders' charge. Bound copies have been forwarded to our agents in Boston, New-York, Philadelphia, Baltimore, Washington, Alexandria, Richmond, Savannah, New-Orleans, St. Louis, Nashville, Hartford, Utica, Greensboro', Ga. and Norfolk, Va.

☞ If it is noted by punctual agents, that any subscriber wishes his paper continued *till forbid*, it will be so continued, the agent holding himself responsible for the subscription.

In our next volume, we intend to dispense with advertisements, and print a semi-annual or quarterly advertising sheet, providing sufficient encouragement is given.

TO SEEDSMEN.—A young man who has been engaged in the seed business for a number of years, wishes to obtain a situation in a similar establishment. He is thoroughly acquainted with the business in all its branches, and can furnish testimonials from his last employer as to capability, and a line addressed to R. S. care of WM. THORBURN, Seedsman, Albany, N. Y. will meet with attention. Albany, Dec. 1st, 1839. 1t

---

FRUIT and ORNAMENTAL TREES, ROHAN POTATOES, &c.—An extensive assortment of the finest varieties of Fruit Trees, and Ornamental Trees of large size. A fine collection of Herbaceous Plants, Pæonies, Roses, &c. 80,000 genuine Morus Multicaulis of large size, the growth of Virginia. Also, 1,000 bushels Rohan Potatoes. Orders addressed to the subscriber will receive prompt attention.

Newton, (Mass.) Dec. 1, 1839. JOHN A. KENRICK.

MORUS MULTICAULIS.—25,000 trees for sale, either in quantities or all together, and to be delivered at any time that may best suit the purchaser. They are from imported cuttings, of the genuine Morus Multicaulis, were planted in May last, and are of the most vigorous growth, measuring from three to five feet in heighth, with large collateral branches. Purchasers are invited to call and see them, at the residence of Gen. Morgan Lewis, Staatsburgh, Dutchess county, state of New-York, where the owner lives, as he thinks they will not suffer by a comparison, with any in the United States. Staatsburgh, Dutchess co. Sept. 11, 1839. [oct. 4t] MATURIN LIVINGSTON.

ALBANY NURSERY.—This establishment now offers perhaps the best collection of Pears now in the country; [see the June number of the Cultivator.] Also, Apples, Peaches, Plums, Ornamental Trees, Green-House Plants, &c. &c. A catalogue will soon be printed, and forwarded to order. Address J. BUEL & Co. post-paid. tf

---

HARPERS' SCHOOL DISTRICT LIBRARY, second series—price $20, including a case. From the Hon. JOHN C. SPENCER, Secretary of State and Superintendent of Common Schools.

Office of Superintendent of Common Schools,
Albany, October 30, 1839.

Messrs. Harper & Brothers—Gentlemen—I have received the second series of the School District Library, published by you, and have carefully examined it. It gives me great pleasure to express my entire approbation of the books individually, and of the selection as a whole. A large number of excellent books may be easily found in our language; but to select only a small number of forty or fifty in reference to the wants and taste of the community, so that they shall embrace subjects sufficiently various to interest and yet impart the largest amount of instruction, is a task of much difficulty. This you have accomplished. And I feel bound to say, that I consider this series superior to any other collection, for the same purpose, within my knowledge. While you have consulted novelty in having some original works, you have not sacrificed utility, but have studied to promote it. The cheap price at which it is afforded is, I believe, entirely unparalleled. No person who purchases it, either for a district circulating library or for his family use, will ever regret the bargain.

I cannot forbear acknowledging the spirit and enterprise which have carried on and completed the publication of these books in time to enable the school districts to procure them before the navigation of the canals is closed. Very respectfully, your ob't serv't. JOHN C. SPENCER.

51, 52. *Life and Works of Dr. Franklin*, with a portrait on steel; new edition; in 2 vols.

53, 54. *The Farmer's Instructor;* consisting of essays, practical directions for the management of the farm, garden, &c. By the Hon. Judge Buel; with engravings; in 2 vols.

55, 56. *The Pursuit of Knowledge under Difficulties;* its pleasures and rewards; illustrated by memoirs of eminent men; in 2 vols.

57. *Animal Mechanism and Physiology;* being a plain and familiar exposition of the structure and functions of the human system; designed for the use of families and schools; by J. H. Griscom, M. D.: illustrated by numerous engravings.

58. *The Elephamt* as he exists in a wild state and as he has been made subservient in peace and in war, to the purposes of man; illustrated by numerous engravings.

59. *Vegetable Substances used for the food of Man;* illustrated by numerous engravings.

60, 61, 62, 63, 64, 65. *Universal History*, from the creation of the world to the decease of George III. 1820; by the Hon. Alexander Fraser Tytler and Rev. E. Nares, D. D. ; edited by an American: in 6 vols.

66. *Illustrations of Mechanics;* by Professors Moseley and Renwick; with numerous engravings.

67. *Narrative of Discovery and Adventure in the Polar Seas and Regions;* by Professors Leslie and Jameson, and Hugh Murray, Esq.; with maps, engravings, &c.

68, 69. *Paley's Natural Theology*, with illustrative notes; by Henry Lord Brougham, F. R. S. and Sir Charles Bell, K. G. H., F. R. S., L. & E.; with numerous woodcuts; to which are added preliminary observations and notes, by Alonzo Potter, D. D.; in 2 vols.

AMERICAN BIOGRAPHY—Edited by JARED SPARKS, Esq. viz.

70. Life of John Stark, by Edwaid Everett. Life of Charles Brockden Brown, by William H. Prescott. Life of Richard Montgomery, by J. Armstrong. Life of Ethan Allen, by Jared Sparks. With a portrait.

71. Life of Alexander Wilson, by William B. O. Peabody. Life of Captain John Smith, by George S. Hilliard. Portrait.

72. Life and treason of Benedict Arnold, by Jared Sparks, Esq. Portrait.

73. Life of Anthony Wayne, by John Armstrong. Life of Sir Henry Vane, by C. W. Upham. Portrait.

74. Life of John Eliot, the apostle to the Indians, by Convers Francis. With a portrait.

75. Life of William Pinkney, by Henry Wheaton. Life of William Ellery, by E. T. Channing. Life of Cotton Mather, by Wm. B. O. Peabody. With a portrait.

76. Life of Sir William Phips, by Francis Bowen. Life of Israel Putnam, by O. W. B. Peabody. Memoir of Lucretia Maria Davidson, by Miss Sedgwick. Life of David Rittenhouse, by James Renwick. Portrait.

77. Life of Jonathan Edwards, by Samuel Miller. Life of David Brainard, by Wm. B. O. Peabody. Portrait.

78. Life of Baron Steuben, by Francis Bowen. Life of Sebastian Cabot, by Charles Haywaid jr. Life of William Eaton, by Cornelius C. Felton. With a portrait.

79. Life of Robert Fulton, by Professor Renwick. Life of Henry Hudson, by Henry R. Cleveland. Life of Joseph Warren, by Alexander H. Everett. Life of Father Marquette, by Jared Sparks. Portrait.

80. *The Travels and Researches of Alexander Von Humboldt;* by W. Macgillivray, A. M. with engravings.

81. *The History of Greece;* by Dr. Goldsmith. Prepared by the author of "American Popular Lessons," &c.

82. *Natural History of Birds;* their architecture, habits, &c. with numerous engravings.

83. *Familiar Illustrations of Natural Philosophy*, selected principally from Daniell's Chemical Philosophy; by James Renwick, L. L. D. with numerous engravings.

84, 85. *Selections from the Spectator;* embracing the most interesting papers by Addison, Steele, and others; in 2 vols.

86. *The Elements of Geology*, for popular use; containing a description of the geological formations and mineral resources of the United States; by Charles A. Lee, A. M., M. D. Numerous engravings.

87. *The History of Rome;* by Dr. Goldsmith. Edited by H. W. Herbert, Esq.

88. *A Treatise on Agriculture;* comprising a concise history of its origin and progress; the present condition of the art abroad and at home, and the theory and practice of husbandry; to which is added a dissertation on the kitchen and fruit garden. By Gen. John Armstrong; with notes by the Hon. Judge Buel.

89. *Natural History of Quadrupeds;* numerous engravings.

90. *Chaptal's Chemistry applied to Agriculture;* a new translation, with valuable selections from Sir Humphrey Davy and others.

91. *Lives of the Signers of the Declaration of Independence;* by N. Dwight, Esq. One volume, large 12mo.

92, 93, 94, 95. *Plutarch's Lives;* translated from the original Greek; with notes, critical and historical; and a life of Plutarch. By John Langhorne, M. D. and William Langhorne, M. A. Carefully corrected, and printed from the last London edition. In four large 12mo. volumes.

From his excellency W. L. MARCY, late Governor of the state of New-York, dated "*Albany, October* 29, 1839."

"Messrs. Harper—Gentlemen—I have availed myself of the opportunity you have afforded me, to examine the second series of the School District Library; and though I thought the *first* a very judicious and appropriate selection, I am inclined to believe the *second* preferable to it. Some of the books contained in it I have never read, but the subjects of which they treat are such as should in an especial manner be presented to the class of readers for which the library is intended.

"The introduction of libraries into our district schools is a new and highly valuable feature in the system of popular education. The character of the books which you have published for this purpose, and the low price at which they may be obtained, must, I think, facilitate the establishment of such libraries. I sincerely hope that you will meet with sufficient encouragement to induce you to continue the series. I am with great respect, your obedient servant,

"W. L. MARCY."

The above, together with the *First Series*, are for sale by all the principal Booksellers throughout the state.

☞ **MORUS MULTICAULIS** AND OTHER MULBERRIES, &c.—The subscriber is now ready to receive orders to any reasonable amount, for trees of the Morus Multicaulis, or cuttings of the same. The trees are genuine, all being raised by the subscriber, either at his nursery here, or at his *Southern establishment at Portsmouth, in Lower Virginia.* Also, the Elata, Broussa, Canton and Moretti or Alpine, &c.

The collection of Fruits is of the most celebrated kinds. The catalogue of *Fruit and Ornamental Trees and Shrubs, Roses and Herbaceous Plants, for* 1839, is ready, and will be sent to all who apply. In that catalogue, the very best kinds of fruits, so far as proved, are particularly designated by a *star.* All orders will be promptly attended to: and trees, when so ordered, are securely packed for safe transportation. Nonantum Hill, Newton, Mass. 7th October, 1839.

t jan. WILLIAM KENRICK.

MULBERRY TREES.—25,000 Multicaulis, Alpine and Expansa Mulberry trees, and a few thousand Silk Worms Eggs, for sale by S. E. GIBBS & SON,

Address them at Brooklyn. October, 1839. 3t.

MULBERRY TREES.—A few thousand Mulberry Trees are for sale at the Albany Nursery. They consist of the Multicaulis, Brussa, Chinese, that is, the product of Chinese seed, and the common white. The prices will depend upon size and quality. The Brussa is more hardy than the common, and the Chinese about as hardy; and the three kinds are believed to be equal, if not superior, to the Multicaulis, for silk; though it is proper to add, none of the mulberries that we have tried are propagated with so much facility, from buds and cuttings, as the multicaulis. The prices will be conformed to the average market price. tf

---

ROHAN POTATOES.—The subscriber is now prepared to furnish the above very valuable root for transportation, at $5 pr. bbl. until the 1st Nov. delivered at Albany. Persons living at a distance, will find it to their interest to forward their orders early, so they will reach their destination before cold weather sets in. Orders enclosing five dollars, (postage paid) or more, will meet with immediate attention.

CALEB N. BEMENT.

Three-Hills Farm, Albany, Oct. 1st, 1839.–3t

☞ **ROHAN POTATOES.**—Orders received for Rohan Potatoes, at $5 per Barrel, to be forwarded, as may be directed, without delay, by J. BUEL. tf

---

FOR SALE—TWO SOUTH-DOWN BUCK LAMBS.—The subscriber imported, in the fall of 1837, two ewes and a buck, selected from the Earl of Leicester's flock, (Holkham,) of which the above is the progeny. Near Dobb's Ferry, Pa. July 28, 1839.

Sept–tf JAMES A. HAMILTON.

THE SUBSCRIBER has located in Albany, where he is manufacturing his machines for thrashing and cleaning grain. He may be found at **53** North-Market-st. or at his machine shop on Patroon's Creek, near the Manor House. Sept. 2, 1839. [oct. 3t] JOHN A. PITTS.

IMPORTED CATTLE—BERKSHIRE PIGS.—The subscriber intending to return to England, offers for sale his stock of Imported Durham Short Horned Cattle and Berkshire Pigs, at his residence, English neighborhood, Bergen county New-Jersey, five miles from New-York. The stock consists of 15 head of milking cows, 1 two-year old heifer, 4 one-year old heifers, and from 8 to 10 spring calves. Four of the above cows are imported, and the remainder are got by the imported Herd-Book Bulls Dishley, Durham, Wye-Comet, Hall's Comet, Memnon, Admiral, Denton, &c.

BERKSHIRE PIGS.—Ten breeding Sows, in pig and with pigs by them at the present time; from 40 to 50 Pigs ready for delivery at any time, at prices from $10 to $20 per pair, delivered in New-York.

The imported Herd-Book bred bull Bloomsbury is with the Cows for the season, and from present appearance will soon all be in calf. The yearlings and spring calves are all by my bull Snow-Ball, late Minevis, by Wye-Comet, dam Nelle, bred by Israel Munson, Esq. of Boston, got by the imported bull Admiral; grand-dam Rosa, bred by Mr. Munson, by the imported bull Denton, owned by Stephen Williams, of Northborough, Mass.: great-grand-dam Tuberose, bred by Mr. Wetherall, and imported by Mr. Munson.

For further particulars, see Herd-Book; Dishley, page 63; Durham, page 567; Wye-Comet, page 200; Admiral, page 2; Denton, page 43; Tuberose, page 524.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. VI. NO. 5, WASHINGTON-ST. ALBANY, N. Y. DECEMBER, 1839. No. 12.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—Lewis Hill & Co. Richmond, Va.; Bell & Entwistle, Alexandria, D. C.; Gideon B. Smith, Baltimore, Md.; Judah Dobson, bookseller, D. Landreith, and M. S. Powell, seedsmen, Philadelphia; Israel Post, bookseller. 88 Bowery, Alex. Smith. seedsman, P. Wakeman, office of the American Institute, Broadway, New-York; Hovey & Co. Merchants' Row, Boston; Alex. Walsh, Lansingburgh, and Wm. Thorburn, Albany, gratuitous agents; John Thorburn, seedsman and general agent, St. Louis, Mo. E. Valentine, Johnson's Springs, Va. See No. 12, vol. v.

The Cultivator is subject to common newspaper postage.

☞ The published volumes are for sale at the subscription price, or, if bound, the cost of binding added. The bound volumes may be also had of our Agents in the principal cities.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

Close of the Sixth Volume.

This number closes the present and Sixth Volume of the Cultivator. In place of furnishing an extra number, which the late Proprietor and Conductor promised in the June number, when he announced his intention of closing this volume "by publishing a number on the 15th of August, and another on the 15th of October, in addition to the usual monthly publication, in order to have the seventh volume commence on the beginning of the year, when most periodicals commence their volumes," we have substituted, at a great expense, as a frontispiece, an engraved portrait of the late Editor, JESSE BUEL, Esq. taken but a short time previous to his death, by Mr. F. FINK, of this city. It is, as has been universally pronounced by all who knew the original, an admirable likeness;—as a picture, it speaks for itself. Mr. FINK is a young man, and has, in all his works, displayed great ability. The engraving is by Mr. THOS. H. CUSHMAN, also of this city, and recently of the firm of Hall, Packard & Cushman, Bank Note Engravers. Although he may find the branch of engraving here presented, less lucrative than that of making bank notes, yet we are satisfied, he must find it more congenial to his taste, and one which will afford him a far more lasting reputation, if he succeeds as well as he has in the above. He has been constantly employed for the last six weeks in producing this effort, and we can answer for the justice he has done the painting from which he copied, and which, we have no doubt, will prove full as acceptable to our very numerous list of subscribers. We shall furnish all our present as well as future subscribers to this volume, with a copy of the engraving.

We publish in this number, the two last addresses of Mr. BUEL, being convinced they will not only be acceptable, but meet the approbation of our readers. This course appeared advisable, inasmuch as they were his *last efforts* in the cause of his favorite pursuits, Agriculture and Horticulture, and by particular request of our correspondents.

It would not appear strange should the same ideas or sentiments be repeated, still, we think them not the less interesting, and should not be objected to on that account.

We also present a beautiful engraving on wood, (by Mr. R. H. PEASE, of Albany,) being a representation of the Horticultural Coat of Arms, as exhibited by that spirited and enlightened horticulturist, ALEX. WALSH, Esq. of Lansingburgh, at the Horticultural Fair at Niblo's, in New-York. It elicited great praise, and excited the admiration of the thousands who thronged to view it. Much credit is due to the *head* that conceived, and the *hands* that executed it.

We would ask the indulgence of our subscribers, for the lack of interest in our three last numbers; for they have been attended with numerous difficulties. The confusion naturally incident on assuming the "responsibility" of conducting this work, will appear evident to all; and at the moment we were preparing copy for this number, we were called out with the troops, to aid our sheriff in serving certain processes against the tenants of the Van Rensselaer Manor; in consequence of which we were compelled to leave it in the hands of a friend, who has had no experience in such matters.

☞ To our numerous and valuable correspondents, we again tender our grateful acknowledgments, and earnestly hope they will continue to lend us their aid in the great cause we have espoused.

To those gentlemen who have enlisted their services, and acted as agents, we also feel under great obligations for our extensive circulation, and we respectfully solicit a continuance of their favors for our next volume, the first number of which will appear in the early part of January next, under the editorship of the Genesee Farmer, (WILLIS GAYLORD and LUTHER TUCKER, Esqrs.) combined in the Cultivator.

☞ Owing to want of time and space, we have been compelled to lay aside several communications, which will appear in our next volume.

The following table will show the extent of our present circulation.

Horticultural Coat of Arms.

The Horticultural Society of the Valley of the Hudson, held a meeting last September, in Niblo's Garden, in New-York.

The display of Plums, Peaches, Nectarines, Melons, Filberts, Pears, Grapes, &c. &c. were the most choice and inviting. The exhibit of flowers, particularly Dahlias, was truly gorgeous; and the show of vegetables fine. The most conspicuous contributors to the exhibition were, Dr. Torry, Messrs. Prince, Hogg and others, of New-York; Perry, of Brooklyn; Downing, of Newburgh; Holbrook and Kneeland, of Hyde-Park; Mrs. Stephen Van Rensselaer, Buel, Dennison and Wilson, of Albany; Strahan, of Halfmoon; A. P. Heart, of Troy, and Mr. Alexander Walsh, of Lansingburgh. The part of the latter gentleman is thus noticed in the N. Y. Commercial Advertiser:—

"The gentleman whose contributions are most extensive and various, is Alexander Walsh, and to his taste the society is indebted for a very appropriate and beautiful ornament at the head of the Saloon. It is what Mr. Walsh has fitly denominated the Horticulturists' Coat of Arms, forming a pyramid twenty-four feet high, constructed entirely of instruments of horticulture. A thermometer, handsomely decorated, is placed in the centre, with the motto, 'SCIENCE DIRECTS OUR OPERATIONS.' The spade, rake, hoe, &c. &c., covered with a wreath of evergreens, and decorated with a superb variety of dahlias, rare exotics, and native flowers, form the frame work of this fanciful device. From the most prominent parts of the structure, are suspended teazles, madder-root, woad, sumac, perennial flax, &c.; all produced by Mr. Walsh, emblematical of the aid horticulture affords to manufactures. The silk business is fully represented by the eggs, reeled silk, and a tasteful display of the cocoons, and wreaths of silk moth. Near the centre, the grape, and that which maketh the heart glad, corn, wine, and oil, are justly represented. The pedestal and platform, some 40 feet long, is loaded with some fifteen or twenty varieties of plums, also apples, pears, filberts, a profusion of choice and rare vegetables, a diminutive bee hive, and a sundial. On the right, a little raised from the pedestal, are placed a variety of rural engravings. Copies of the New-York, New-England, Michigan, and Genesee Farmers, the Cultivator, Boston Horticultural Register, Gardeners' Magazine, London Horticultural Register, Robert Mudaie's Botanic Annual, and other publications, fully to complete the Gardener's Budget, have likewise been placed upon the table. The whole furnishing a beautiful illustration of Mr. Walsh's motto, which is—

"*Son utile ainda que briconda.*"
"I am useful, even when sportive."

"The annual discourse* was delivered by WILLIAM EMMERSON, Esq. and was such a production as might have been justly expected from the elegant scholarship and high attainments of the speaker."

We have endeavored to gratify the readers of the Cultivator, by a faithful representation of the *Horticulturists' Coat of Arms;* (see engraving in front of the volume.) The wood cut represents the entire pyramid and pedestal, but not the platform, which was too extensive for our page, and not altogether connected with the Coat of Arms. It was a neat, showy structure, which added much to the general effect in the Saloon. The centre shows the gardener's tools; on the right is the library for the improvement of his art; and on the left the plentiful fruits of his labors.

We should be pleased to see a steel engraving in some of our Annuals, giving the entire of this unique and singularly attractive device. We have presented a memorial of the principal part; a drawing of the whole we can furnish.

Judge Buel's Address,

To the Agricultural Institute of New-London and Windham Counties.

GENTLEMEN—Farmers and Mechanics form the great body of our population. Their influence upon public manners and morals is consequently great. Their labors constitute the principal source of our wealth.—They are to the community what the body is to the animal system—the seat of nourishment, of vigor, and of life. Though reciprocally beneficial to each other, the limbs would perish without the support of the body, while the body could live without the aid of the limbs. So in society, the different professions are reciprocally beneficial to each—they are all necessary to social and refined life; yet they are not all *equally* important to our well being. We might better spare a limb than to suffer the body, upon which all the limbs are dependant for life, to sicken and die. Productive labor, then, being the great fountain of wealth, and the source of moral health to the body politic, it should be fostered and honored, that it may more abound; and it should be enlightened, that it may better subserve its high purposes to society.

It must be apparent to all who can carry back their recollections to the commencement of the present century, that the useful arts have been undergoing, and are continually undergoing, rapid and wonderful changes in the economy of labor, and in the utility of results.—This change has been less, or rather less general, in the business of farming than it has in the mechanic arts, owing to the fewer facilities which the farmer possesses of acquiring useful knowledge in his business, by reading and personal observation. An improvement in the mechanics arts is no sooner made, than it becomes known, is adopted, and rendered profitable, in every part of the country; while improvements in agriculture, however important, travel slow, are received with distrust, and adopted with reluctance. To keep up with the spirit of the age—to prosper in our business and benefit the community, we must sedulously avail ourselves of all the prominent improvements which are going on in agriculture and the mechanic arts, and endeavor to infuse into those around us a spirit of industry, emulation and enterprise. For man does not live by his own labor alone. His success depends upon his being able to sell the surplus products of his labor to those who are able to pay for them, and to exchange the avails of his sales for such articles as he does not produce, and of which he stands in need. Hence he who is surrounded by prosperous neighbors can sell and buy to better advantage than he who is surrounded by poverty and want. I therefore lay down this proposition, that a man, whatever be his honest business, is profited by the prosperity of his neighbor, be that neighbor a farmer, a mechanic, a manufacturer, a merchant, a lawyer, a physician, or a clergyman: and that consequently, the true way to advance his individual interest is, to endeavor to improve the condition of his neighbors. It is a bad trait in the human character, and one which generally defeats its object, but which is nevertheless too conspicuous, that many seek to elevate themselves by depressing those around them—as if the poverty and misfortune of the one, added to the merits and virtues of the other. Not only self-interest but philanthropy and Christianity enjoin, that when we have provided comfortably for ourselves and our own, we should render all the assistance in our power to our brother who stands in need of our aid. The selfish being who lives but for himself, may, by amassing useless wealth, enjoy his hour or his day of fancied greatness; but he can never realize the pure, the elevated pleasures which flow from a life of active benevolence to the human family.

---

* We should be pleased to have a copy of this address for publication.—*Cond. Cult.*

The farmers and mechanics who have united in this celebration, have many interests in common, and they do well to cultivate, in this way, kind feelings towards each other. They are neighbors; and there should be an interchange of good offices maintained between them, to heighten the pleasures of social intercourse—one of the chief enjoyments of society. It has been said that in fixing on a location for life, the grand requisites to comfort are, pure air, good water and a healthy soil; yet these seem incomplete, at least as regards comfort, without the addition of good neighbors. And with a right temper of mind, an individual may contribute much to make good neighbors. But the interests of the farmer and mechanic are otherwise intimately connected. They are mutually dependent upon each other for the comforts and necessaries of life. The farmer wants the fabrics of the mechanic—the blacksmith, the hatter, the cabinet-maker, the tailor, &c; and these in turn want the bread-stuffs, the meat, the butter and cheese, the roots, and the raw materials of the farmer. Both classes are best accommodated by an interchange of commodities. If the farmer can exchange with the mechanic, at home, enough of the surplus products of his farm to buy what he wants of the mechanic, the expense of transportation to market, of both parties, is saved, and the uncertainty of sale, and the danger of loss, obviated. It is much better to exchange, at home, the products of each other's labor, for a fair equivalent, than to trust to the contingencies of a foreign market.

On the old continent, some men are born to rank and privilege, and others are born to servile labor. Arbitrary laws have prescribed, to a great extent, a man's condition in life, ere the infant breathes the vital air.—Arbitrary power has perverted, then, the laws of equality, which were intended for the human family, and has enacted artificial distinctions, which industry and genius can hardly surmount, nor hereditary rank hardly sink below. We know no such distinctions among us. We recognize neither the hereditary distinctions conferred by birth nor wealth. With us

> "Merit makes the man,
> Want of it the fellow."

And this merit is the reward of individual effort, the prize of intelligence, industry and virtue. And the competition is open to all We are all endowed with natural capacities for improvement, like the soil we cultivate; and our reward, like the harvest, will be greater or less, in proportion to the measure of our self-improvment. But as with the rich soil, where nature has done most, man generally does least, so with the mind, where the expectations from parental aid are the greatest, the offspring seem least anxious to exert themselves to fulfil the high obligations imposed upon all. Poverty and want are often the strongest stimulants to physical and mental exertion; and when a laudable ambition is awakened to excel in any useful pursuit, it seldom stops at mediocrity. Adversity, more than prosperity, is the school in which men learn wisdom.

There are other high responsibilities resting on the farmer and mechanic, which should stimulate them to mental and moral exertion. They constitute the physical and political strength of our country. If they are ignorant, poor and dependent, they are very liable to become the tools of demagogues, and the corruptors of public morals. If they are intelligent and prosperous, they will be exemplary in their habits, strong in their influence, and independent and patriotic in the bestowing of their suffrages.

With these incitements to improvement, and these duties and responsibilities before them, the farmer and the mechanic have abundant cause to put forth their best exertions, to study the principles of their business, and to profit by the genius and talents of others who excel in their respective callings; for however a man is gifted naturally, or however successfully he calls his physical and mental powers into action, he may learn much from the skill and practice of others.

The establishment of fairs is one of the most efficient means of improvement. They bring together the ingenious products of labor, from the exhibition of which every individual may learn something useful, to improve his mind and his business. They promote friendly intercourse and excite to laudable emulation; they enable their members to see, in contrast, the weakness of want and the strength of innate independence; in fine, they put in motion a thousand springs to self-respect, to industry, and to usefulness.

Another prominent means of improvement is the periodicals of the day, which treat of agriculture and the mechanic arts. These record the discoveries and improvements which are daily making in their respective branches of productive labor, and are written by practical men, or by men of science, with a view to benefit labor. I am sure I do not exaggerate, when I say that individuals have been benefitted hundreds of dollars by an outlay of one dollar for a publication of this kind, in consequence of the useful information it has given him in the prosecution of his business. These discoveries and improvements in farming and the mechanic arts are continually going on, and he that will, may, by a moderate expenditure, largely profit by them.

The great secret of success in agriculture, consists in adapting our crops to our soils, in fitting the soil for their reception, in feeding them well, and in giving them proper culture; and the great obstacles to improvement are, ignorance of the principles or science of agriculture, a blind adherence to old practices, and a parsimony in expenditure. We better understand the economical management of animals than we do of plants. We all know that we cannot make fat beef, or pork, or mutton profitably, without we feed high. It requires a certain amount of food to keep an animal in condition—all beyond this which the beast can consume, digest, and assimilate, is virtually converted into flesh. Now, it makes a vast difference whether this extra food is converted into flesh in three months or twelve months; because, in the former case, three-fourths of the ordinary food required to sustain life and condition for a year, is saved to the feeder, besides an equal expense in attendance. It is precisely so with our crops. *One* well fed acre is more profitable than three poor fed acres, because it requires but one-third of the labor, and will, oftentimes, give an equal or a greater product. Take Indian corn for example, the average product of which I will assume to be thirty bushels an acre. Now, if we make an acre of suitable soil rich with 25 loads of unfermented dung, and tend the crop well, we may get ninety bushels of corn from the acre—and the amount has often been swelled to one hundred and one hundred and twenty. Here, then, is a net of gain of sixty bushels by feeding an acre well, over the nett gain of an acre not fed at all. In regard to the cost of the manure, call it, if you please, $25, and consider it capital expended. If you deduct this from the profits of the well fed acre, there would still remain a difference in favor of the latter, according to the common scale of prices, of $35. If you merely charge the interest on the outlay, this would be $1.50, and would diminish the difference between the good and bad acre but this amount, or would still leave the crop on the rich acre worth $58 more than that on the poor acre. Estimate the farmer's corn crop at ten acres, and you will perceive that the cultivator of the ten good acres realizes a nett profit of $580 more than the cultivator of the ten poor acres.—Carry out this comparison to the products of the whole farm, and we shall at once discover why the good farmer finds a profit in an outlay every four years, of $20 an acre, in enriching his lands. But if we suppose—what is, in fact, the truth that the long manure, which causes this great increase in the corn crop, is as good for the next crop as it would have been had it been summer yarded, as was wont to be, and is now often the case, the absolute additional expense is nothing—the food of the corn crop is absolutely saved to the farm. I might carry these illustrations to other crops, to farms, and to districts of country. In my late journeyings in the States of New-York and New-Jersey, I have seen many farms, and some districts, where the intrinsic value of lands has been enhanced a thousand per cent. or in a ten-fold degree, by the almost magic influence of improved husbandry, based upon the principle of working no more land than can be kept rich and worked well. Having gone into details in these matters on recent public occasions, I forbear repeating them here.

It should be borne in mind, that the elementary matters which constitute animals and vegetables are similar, though differently combined in animals and plants, and in different animals and in different plants. They are principally oxygen and hydrogen (the constituents of water,) nitrogen, which, with oxygen, forms the volume of the atmosphere, and carbon, the substance of charcoal. These elementary matters are found in all the combinations of matter—in a solid form in animals, vegetables, and rocks. By the interposition of caloric, or the matter of heat, they are rendered liquid and gaseous—liquid in water, and gaseous in the atmosphere. When they disappear in one form, they take another—they are never lost, never annihilated. They perform a constant routine, under fixed and established laws, termed natural laws, for the benefit of man, and for the order and preservation of the natural world.—As soon as the animal and vegetable cease to live, a decomposition or separation of their elementary parts commences, if exposed to the agency of heat, air, and moisture, and goes on until their organic forms are lost, and their elements are mingled with the soil, and fitted again to enter into new vegetable combinations, and are taken up, with the moisture of the soil, by the spongioles, the mouths of plants, or are imbibed by their foliage, and become again parts of new and living organic matters. Thus the products of the soil are consumed by the animal, and these elementary matters become flesh and its natural appendages, or they are voided by the animal, and decay upon the soil. When deprived of their vitality, they soon resolve themselves into manure, and when these animal and vegetable substances, known by the general name of organic matters, are blended with the soil, they become the proper food for new generation of vegetables.

These facts suggest to the farmer who would keep up the fertility and productiveness of his soil, the necessity of—

1st, Consuming his crops, as far as is practicable, upon his farm, or of returning to it an equivalent, in manure, for what he carries off;

2nd, Of carefully husbanding every animal and vegetable substance which he can command, of preserving it from waste, and of faithfully and judiciously applying it to the soil, as food for his crops; and

3d, Of studying those laws of nature which govern, to a greater or less extent, the whole business of the farm, and which can never be violated with impunity.

I am aware that something further is necessary to satisfy the wants of the farmers in old settled districts—that their lands have been deteriorating under a bad, a skinning system of husbandry, until they require extra stimuli, other than the ordinary vegetable products of the crops, to bring them into a state of profitable culture. These extra means of inducing fertility are abundant. They may be found in almost every district or upon every farm, and no intelligent or spirited farmer need hesitate about employing them. As I have said, nothing is annihilated. The vegetable matters, the humus, or the geine, or whatever term we choose to give to the food of plants, which originally existed in our soil, are not lost—they have merely changed position. It is the province of the farmer to restore them to their place of usefulness, and his reward will be commensurate with his labors. These fertilizing matters, it is true, have, to a great extent been lost to present, though not to future usefulness. They have been dissipated by winds; they have passed into the sub-soil; they have been wasted by the rains, washed into swamps, rivers, and the ocean;—and yet they are, in a measure, recoverable, and may be made again to feed our crops and renovate our husbandry. These great changes cannot be effected by ignorance and hereditary conceit, nor in a day. They must be the work of patient industry, of liberal expenditure, of scientific knowledge—of a generation. I will proceed to enumerate some of these means of renovating the fertility of the soil:

The first I shall name is a thorough system of draining. Many of our wet grounds have become rich in the elements of fertility at the expense of those which are naturally dry. There are certain coarse grasses which indicate the presence of surplus water within the range of their roots. In these vegetable matters, the food of plants do not decompose, or, to employ a term analagous to animal economy, do not digest, by reason of the exclusion of heat and air. No cultivated crop will do well in such situations, not from a lack of the elements of vegetable food, but from the inability of the vegetable stomach to digest it, and which, like the dyspeptic stomach of man, is rather injured, than benefitted, by excess. Drain these lands thoroughly. Let in the genial influences of the sun and the atmosphere, and cultivate them—the process of digestion or decomposition will go on, and the soil will render a liberal tribute to the cultivator.

In some cases draining will not suffice to induce fertility, by reason of an excess of vegetable matter, which resists putrefaction. This is no misfortune to the owner. If this peaty or vegetable matter, is placed in his cattle yards for a season, to the depth of twelve or eighteen inches, exposed to the tread of his cattle, and becomes intermingled and saturated with their dung and urine, or placed in piles with fermenting materials, it will undergo fermentation, and may then be blended with the soil to certain advantage. Another mode of converting these matters into the food of vegetables, is to pare and burn it, in smothered piles, and to spread the ashes upon grain and grass grounds; and still another mode, which has been successfully practised, is to carry on to these drained grounds, earthy materials, and to blend them with the vegetable surface.

The rivers, the salt marshes, and the sea are prolific in the materials of fertility. Their vegetables, their mud, and their fish, are all convertible into the food of farm crops.

From the materials already enumerated, great fertility has been imparted to farms which had been worn out, by bad husbandry. On mentioning to a visitor from South Carolina, Mr. Crowell, the other day, that I had visited a farm upon Staten Island, Mr. Seeley's, where the proprietor, besides manuring well his crops of the season, had accumulated a surplus of 2,500 loads of excellent compost, from the cattle yards, the swamps, and the sea, within his jurisdiction, my visitor remarked, that he had almost equalled that himself, for he had actually applied to his plantation, during the year, twenty thousand loads of like compost, with the addition of such materials as the cotton crops afforded. Mr. Crowell is a large planter. He cultivated, this year, two hundred acres of sea-island cotton. When he first turned his attention to manures, twelve years ago, he became, he told me, rather the butt of ridicule to his neighbors, than the subject of commendation. His continuing the practice, and his increased outlay upon it, is a sufficient evidence that he finds it profitable; while his neighbors are now giving their approval, by adopting his practice.

There are still other sources of fertility within the farmer's reach, which he may employ to profit. In a late jaunt in New-Jersey, I was surprised to find farms and districts, where I had been led to expect, from report, a poor sandy soil, a bad system of husbandry, and a depressed farming population—I was agreeably surprised to find, I say, instead of these indications of poverty and want, a sandy soil, to be sure, and naturally poor, but much of it made rich and productive—highly cultivated farms, and an intelligent, prosperous population. This fertility had been in a manner created by the enterprise of the inhabitants, in applying to their soil, often at the expense of twenty dollars or more an acre, the lime of Pennsylvania, the dung and street dirt of New-York and Philadelphia, the marl of their own State, and the animal and vegetable products of their own waters. Some of these materials, although not affording direct sustenance to plants, operate mechanically or chemically to the improvement of the soil, and tend essentially to increase its productive powers.

Another means of recovering the fertilizing materials of the soil, is deep or subsoil ploughing. Much vegetable matter has been carried down from the soil into the subsoil, by the operations of water. By breaking up the latter, we not only deepen the tilth, the pasture of plants, but by exposing it to atmospheric influence, we render the vegetable matter in it soluble, and adapted to the wants of the crop. We thus restore to the upper surface much of the fertilizing matter which has been rendered useless by filtration.

Another means of restoring fertility to worn-out soils, or of preserving or economizing it on unexhausted lands, is by the culture of root crops, and other green crops, as food for cattle, and for crops. This class of plants yield more food for both, than any other class; and they exhaust the soil less than any other class—for they are seldom permitted to mature their seeds, when the greatest requisitions are made upon its riches, and draw much nourishment from the atmosphere, which is always charged with the gaseous food of plants, as well by their leaves as their roots, the soil being kept permeable to the atmosphere, by the culture they receive. As cattle food, root crops, particularly the Swedish turnip, the beet and carrot, quadruple the amount that is given by grain or grass; they break and pulverize the soil by their tap roots, they clean it by their culture, and they return to it most in the form of manure. Clover and other green crops, buried in the soil by the plough, are a cheap means of increasing fertility, which every farmer has at command. A bushel of clover seed will suffice for six acres, sown with small grain. The next or second autumn, it will give to the soil, if ploughed in, at least five tons to the acre, in tops and roots of vegetable matters, which are soon rendered soluble, and fitted to become a part of a new vegetable structure. The farmer, therefore, gets thirty tons of green succulent matter in return for his bushel of clover seed besides the benefit to the soil of pulverization by means of the tap roots of the crop.

This brings to my mind an old practice, which has in a measure been exploded, as involving a waste of labor and manure—I mean the practice of summer fallowing. It has been ascertained that the quantity of vegetable matters contained in old sward, amounts to twelve tons an acre. If the ley is cross-ploughed, this vegetable matter is turned to the surface, generally when it is in an active state of fermentation or decay, to the wasting influence of the sun and winds, and at least one-half of its fertilizing properties are lost to the soil. The principal object of a summer fallow is to subject the soil to thorough pulverization—a very commendable object, but which I think is as well effected, on the first furrow, by the harrow and the natural decay of the vegetable matters of the sod. This is every where penetrated by the roots of grasses, &c., and if the sod is well turned, these undergo speedy decomposition, and leave the soil light and loose, pervious to heat, air and moisture, essential agents in vegetable growth. The modern practice is to substitute for the naked fallow, a fallow crop, as potatoes, corn, oats, &c. upon the first furrow, preparatory to a crop of winter grain. The advantages of this practice are, the manure is all saved to the soil, the expense of labor is diminished, and an additional crop is obtained. The only plausible reason now urged for naked fallow is that it is necessary, on tenacious clays, to clean the land.

The alternating system of husbandry has not obtained among us that consideration which its importance demands. It is well known that ordinary lands will not bear a succession of the same crops without a successive diminution of product; and that if grain, grass, and roots are alternated or succeed each other, the decrease of fertility is much less apparent. This is ascribed to the well authenticated fact, that different plants exhaust different fertilizing properties of the soil, or in other words, that each species requires a specific food, which other species do not take up. It is now generally conceded that wheat will not do well in a soil which has no lime in its composition—that clover and lucerne require gypsum—that flax cannot be raised on the same ground oftener than once in six or eight years, with advantage. These facts are explained upon the ground that on analyzing wheat, it is found to contain lime; clover on analysis, has yielded gypsum at the rate of four bushels the acre—and the supposition is, that a crop of flax exhausts the soil of some property essential to its perfection, which it takes years to restore. The crops can derive these supplies from no other source than the soil; and if the supplies are not there, the crop will be either deficient or defective.

There is still another reason to offer for alternating crops. The soil, if in grass, becomes annually more hard and compact; the roots are consequently restricted in their range for food; the heat and atmosphere become partially excluded, and the decomposition of vegetable food is arrested. The consequence is, that the finer grasses gradually disappear, or run out, as it is termed, and the grass crop gradually diminishes. If ploughed and cropped occasionally with roots, these inconveniences are obviated; the soil is broken and pulverized, and rendered pervious to solar and atmospheric influence, and the vegetable food which it contains is thereby render soluble; and if manure is given to the tillage crops, as it should and can be once during a course, the soil will become renovated and fitted again to receive the grass seeds, with the prospect of a greatly increased burthen of hay.

The grasses are however not the only system of crops that are impoved by the alternating system of husbandry. The tillage crops, in turn are alike benefitted, not only from the advantages of change which I have endeavoured to point out, but from the vegetable matters of the sward, which, instead of remaining in a measure dormant and useless, are decomposed and become the active food of the crop; while the root crop, by their pulverizing and cleansing influence upon the soil, improve it, mechanically and chemically, for both grain and grass.

The arguments that I have urged for enriching your lands, and cultivating well what you do cultivate, apply with equal force to your domestic animals. It costs as much to keep a poor cow, a poor sheep, or a poor hog, having reference to breeds, as it does to keep a good cow, a good sheep, or a good hog. And yet such is the difference in the breeds of animals, and sometimes between individuals of the same breed, that the good animals will return twice, thrice, and sometimes four times as much in product as the poor ones, for the expense of their keep. The mule is supposed to have a preponderating influence in the character of their progeny, and will multiply more rapidly than the female, the cross of any improved breed. Those, therefore, who do not choose to go to the expense of buying superior animals of both sexes, can, by purchasing a male, progressively improve their stock at a moderate outlay. If the best animals are retained for breeding, and kept in good condition, especially when young, the progress of improvment will be greatly accelerated. It is by judiciously selecting good animals as breeders, and by taking proper care of them, that the favorite breeds of domestic animals have been brought to their present state of unrivalled excellence in Europe. An observance of the rules will produce the same results here, in due time, that has resulted from their observance in Europe.—Cattle are also essential to keep up the fertility of a farm. They convert the forage of the farm into meat, milk, and manure. The meat and milk go to enrich the pocket, and the manure to enrich the soil, and feed the crops.

As a general remark, it may be said, that labor and capital can be expended in no way more profitably by the farmer, than by enriching his lands. God has given to us all the elements of fertility, of plenty, and of happiness. He has given to man the capacity of appropriating them to his own use. He has commanded him to exercise those capacities with dilgence; and although He has not promised, He seldom fails to bestow upon those who honestly keep the command, the highest rewards in temporal happiness.

The orchard receives less attention than its importance demands. If men do not drink cider, they must use vinegar and will eat apples. The orchard supplies a grateful dessert, and many economical culinary dishes, for our tables—and often profitable commodities for the market; and it has of late become a source of substantial profit for the food which it affords to farm stock of every description. The apple, whether sweet or sour, affords much sugar, one of the most nutritious properties found in vegetables, which is readily converted into beef, pork or mutton, by the domestic animals on the farm. It is asserted by some, who have experimented in the matter, that a bushel of apples is worth as much, for these domestic uses, as a bushel of potatoes. If this is true, or if apples are worth half or quarter as much as potatoes, an apple orchard is a valuable appendage to the farm; for an acre will often give from four to ten times as great a product in apples as it will give in potatoes, and without the expense of annual cultivation. In our zeal to promote the temperance reform, I fear some have neglected this branch of farming economy too much. The old orchards are disappearing, and few new ones are planted. We may as well discountenance the raising of rye as of apples, as both are liable to be perverted to evil purposes; yet we may use both without abusing them. Wisdom, like truth, is often the medicine between two extremes.

But whatever objections may lie against the orchard, none, I am sure, can be urged against a well cultivated garden. This affords almost a constant change of choice delicacies for the table, at once grateful to the palate, and highly conducive to health. No man eats so good fruits and vegetables as he who raises them, for none can so well enjoy them in all their freshness and perfection. A good garden is a matter of farm economy; for while it may be made to contribute largely to the sustenance of the family, its labors may be performed at odd times by the laborers of the farm, or by those who can or will do little else, without much expense. The object of our toil, as I have observed, is to secure the rational enjoyments of life. There is no profession which can gratify these indulgences to a greater extent than the farmer, if he will, from the varied products of his farm and garden.

There are other sources of enjoyment, in the garden, besides the innocent gratification of the animal appetites. It may be a source of high intellectual enjoyment, of useful instruction, and of moral improvement. It stimulates to the study of natural science, tends to purify and elevate the mind, to prevent the formation of bad habits, and to increase the delights of HOME, where the social and domestic virtues can only be well nutured and enjoyed. So salutary is the moral influence of a highly cultivated garden, that it has been considered a strong indication, wherever it is seen, of high intellectual and moral worth in the possessor. God put our first parents into the garden "to dress it and to keep it," and God commanded the man saying, "of *every* tree of the garden thou mayest freely eat," except of the forbidden tree.

The utility of the silk business, as an auxiliary source of profit to the farmer, no longer admits of doubt, and so much capital has been vested in trees and buds, that this must become a branch of national labor. And to no class can it be rendered more profitable than to the farmer, if judiciously managed. He can buy, however limited his means, a few mulberry trees; these he can multiply himself, with but little labor; he can plant them about his fences and waste grounds; he can purchase a few eggs to begin with; an out building, or a spare room, may be converted into a cocoonery; and without further expense the children and females of his family can gather the leaves and take care of the worms. When the cocoon are perfected, he may increase his eggs, and find a ready demand, and a fair price, for the surplus cocoons. The avails of the sale, be it two dollars or five hundred dollars, may be virtually considered as nett profits to the farms. Fifty years ago I was familiar with the management of the silk worm in my native town, then in the county of Windham. Under every disadvantage of those times, it was then profitable, and an auxiliary branch of household labor. I have every reason to believe it may be rendered much more so now.

In regard to the mulberry best adapted to farm economy, much speculation is afloat, and differences of opinions no doubt honestly exist. I think it may be laid down as a natural law, that plants attain to highest perfection, for all useful purposes, in the climate and soil where they are found indigenous; and that their useful properties are diminished in proportion as they are more or less removed from their natural zone. When the public mind has settled down to sober reality, I think this law will be found to apply to the mulberry; and that these species and varieties will be found to be best which are naturally best adapted to our climate and our soil. In corroboration of this fact, it may be stated, that in Italy, whence we receive our best, and most of our sewing silk, the leaf of the black mulberry, which is there apparently indigenous, is almost exclusively employed for the production of this article. The white mulberry, which is perfectly hardy in France, has a decided advantage there over other varieties.—The Brussa, in the mountains of Asiatic Turkey, and the Alpine, from the Alpine regions of Europe, both hardy species, are for the like reason deemed superior in elevated or northern regions, where they withstand the rigors of winters. The native red mulberry of our forests, (*Morus Rubra,*) though it has neither "far-fetched or dear bought" to recommend it, will ultimately, I think, be found to be as good as any kind we can cultivate. All the species and varieties cultivated will no doubt produce good silk, and some better in the north than in the south—as is the case with the apple, the pear, the peach, the plum, &c. each variety having its favorite zone and soil in which it best develops its highest flavor. In selecting fruit trees, it is always better to take them from a colder than from a warmer climate, because they will be more hardy, and mature their fruits in higher perfection. But a word more of the red mulberry. I have had presented to me a handkerchief, a most beautiful and substantial fabric, produced by the silk-worm from this native species of the mulberry. I have also several samples of sowing silk, of great strength and beauty, produced from like materials. And I am advised by Dr. Martin, a highly respectable gentleman from Kentucky, that his neighbor has sold sewing silk to the amount of $900 a year, for several years, produced by worms fed entirely on the native red mulberry; and that he has rejected offers of all other kinds of the mulberry, considering this decidedly the best.

If these observations upon the laws which govern the vegetable kingdom are correct, they plainly suggest to the cultivator, who raises the mulberry tree to produce silk, to select those kinds for his plantation which are most hardy, and which will occasion the least trouble and expense in preserving.

I should take pleasure, gentlemen, in giving you my views upon many other subjects which pertain to your business. If what I have said shall be of any value to you, I shall be happy in the consciousness of having fulfilled a high personal duty—that of benefitting my native State. If what I have said, shall prove of no value, I have certainly said enough. My object has been, the improvement, in their business, in their standing in society, and in their public usefulness, of the Farmers and Mechanics assembled around me.

The privileges you enjoy, and the opportunities you possess of improvement are great; and with moderate prudence and industry, virtues which always triumph, your condition in society will be respectable independent, and in all probability, happy. Be content, therefore, with your lot—with the business which you have learnt, and are best acquainted with—and strive to improve in it, for your children and your country. *Let well enough alone;* and do not hazard present enjoyments for the precarious chance of doing better, in any business in which you are not practically acquainted, and in which, to you, there will be at least three blanks to a prize. And may a kind Providence smile upon your labors, and bless you in your stores, in your household, and in a pure and approving conscience.

Address of the Hon. Judge Buel,

Delivered before the Agricultural and Horticultural Societies of New-Haven County, Sept. 25, 1839.

I appear here gentlemen, by invitation. to address you on the cultivation of the soil, which it is the object of the associations here convened to promote improvement in. I have been prompted, in the undertaking, rather by a *desire* to render a service, than from a confidence in my *ability* to perform one; and in the few remarks I have to offer, shall need much of your indulgence, for defect in style, and deficiency in matter.

Agriculture and Horticulture are intimately related to each other. They both depend upon the soil, and the animals and plants which it nurtures, for support, for profit, and for pleasure. They both administer, and are indispensable, to our wants and comforts. They are governed in their operations by the same natural laws. Agriculture has cognizance of the farm, which supplies our principal wants; Horticulture, of the garden, which administers to our more refined appetites, to our health, and to the rational pleasures of the mind. The one gives us bread and meat, and the materials for our clothing, the other the choice delicacies for the table, and multiplies around us the charms of floral beauty, and rural scenery. Both tend to beget habits of useful industry and sober reflection, and to improve us in all the social relations of life. It is befitting, therefore, that institutions designed to foster and promote improvements in these primary and associate branches of labor, should unite in their anniversary celebration, and in returning thanks to the Supreme Being, for the bounties of a fruitful season.

Of the utility of these celebrations, and exhibition of the products of the farm and garden which are made at them, I have no kind of doubt. They bring to public notice whatever is new and most valuable, in a business which highly interests us. They perform the work of years, in diffusing useful knowledge in all the departments of rural labor. They awaken, in the bosoms of hundreds, the dormant powers of the mind, which otherwise might have slumbered in apathy. They excite to industry, to emulation, and to the study of those laws which every where control the visible creation, and which enlighten and reward all who humbly seek and follow their counsels. Nor is it the cultivator of the farm and garden alone that are to be benefitted by these exhibitions. Whatever tends to increase and improve the products of the soil, serves to augment the common stock, and enables the grower to supply the market with more and better products, and to buy more liberally of the other classes in return. The merchant, the manufacturer, the mechanic, and the professional man, have all, therefore, as deep an interest in promoting the improvement of agriculture and horticulture, as the farmer and gardener have. Society is in some measure a joint concern, at least so far as relates to what are termed the producing classes; the more these earn by their labor, the greater is the accession of substantial wealth to the community. The amount of honey in a hive, depends not upon the number of bees which it contains, but upon the labor and skill of the *working bees.* The farmer virtually provides for the other classes, and is at the same time their principal patron and customer; and although his labors are too often held to be low and menial, by those who cannot, or will not, appreciate their value, his condition affords the best criterion by which to judge of the welfare of those around him. No *country* can long flourish, or preserve its moral and physical health, whose agriculture is neglected and degraded.—The amount of a farmer's sales, and of his purchases, will depend upon the surplus products of his farm, and upon the profits of his labor. Double these, by an improved system of husbandry, which I feel assured can be done, and which has been far more than realized, in many old districts of our country, and you will double the substantial wealth of the neighborhood, and impart corresponding life and activity to every other department of business. If we look to Spain, to Portugal, to great portion of Italy, to South America, or any other country where agriculture is neglected, or holds but a subordinate rank, we shall find a degraded population, characterized by superstitious ignorance, poverty and crime. Every class of the community, therefore, has a deep interest in promoting the improvement of the soil; and all should willingly contribute their aid towards enlightening, honoring, and rewarding those who are honestly employed in its cultivation.

With regard to the utility of agricultural and horticultural societies, much will depend upon the objects which bring together their members. If they associate for selfish purposes, merely to monopolize the spoils, and withdraw whenever they are disappointed in their sinister hopes, jealousies and apathy will ensue, and the association will fall, as many under like circumstances, have fallen, without public loss or public regret. But if the association is formed for mutual improvement, and in the benevolent and patriotic desire to do a public good —to stimulate and reward industry and enterprise, however humble their condition—and strives by concentrated and persevering efforts, to improve the condition of a district, of a county, or a state,—then will it inspire public confidence, obtain public support and become a public blessing. To illustrate this last proposition, I beg to refer to some associations which have been tried, and whose labors have been crowned with palpable and brilliant success.

The counties of Berkshire, Essex, and Worcester, in Massachusetts, have each, for many years, maintained an agricultural society; and they each distribute ten or twelve hundred dollars a year, one half of which is paid out of the state treasury, in prizes to successful competitors in the various departments of agricultural and household labor. It is said, and I believe with truth, that every dollar thus expended, has made a return of twenty dollars, in the increase of agricultural products which it has caused; and so satisfied are the inhabitants of the benefits of the expenditure, that an increased spirit is annually manifested, by all classes, to maintain and perpetuate these nurseries of industry and improvement.

The Highland Society of Scotland affords another illustrious example of the utility of agricultural associations, when conducted with a view to public improvement. This society was organized in 1784, but so few were its members, and so limited its means, that it attracted but little public notice, nor effected any great improvement in husbandry, till the commencement of the nineteenth century. Yet it had sown the good seed which never fails, under proper management, to yield to the husbandman a bountiful harvest. Nor did it fail in this case. The society now numbers twenty-two hundred members, embracing most of the opulent and influential men of the country, of all professions, and distributes annually in prizes, about seventeen thousand dollars. In no country or district has agriculture made more rapid strides in improvement, than it has in Scotland, since the organization of this society; and although it may not have been the only, it most assuredly has been a principal cause, of this wonderful and salutary change. Up to 1792, the agriculture of Scotland, to adopt the language of the Edinburgh Quarterly Journal of Agriculture, was "wretched—execrably bad, in all its localities! Hardly any wheat was attempted to be grown; oats full of thistles was the standard crop, and this was repeated on the greater part of the arable land, while it would produce twice the seed thrown into it; turnips, as part of the rotation of crops, was unknown, few potatoes were raised, and no grass seeds or clover were sown. A great part of the summer was employed, in the now fertile shire of Fife, in pulling thistles out of the oats, and bringing them home for the horses, or mowing the rushes, or other aquatic plants, that grew on the bogs, around the homestead." But a change soon came over the land. The seed which had been sown by the Highland Society had germinated, and its luxuriant foliage already covered the soil. In 1815, according to the authority I am quoting—"beautiful fields of wheat were to be seen,—drilled green crops every where abounded,—the bogs had disappeared,—the thistles no longer existed,"—naked fallows were abolished, draining was extensively introduced; wet lands were made dry; poor weeping clays were converted into turnip soils; and "whole parishes were completely transformed from unsightly marshes, into beautiful and rich wheat fields, and where the plough could scarcely be driven for slush and water, were heavy crops per acre, and heavy weight per bushel."* The improvements in Scotch husbandry have continued to advance, until, according to the estimate of Sir John Sinclair, and Professor Lowe, both high authority,—until the acreable products of her soil more than double those of our Atlantic states.

The means adopted by the Highland Society to effect these radical improvements in Scotch husbandry, are such as may be employed by us with almost a certainty of corresponding success. "In the days of its youth and feebleness," says the Quarterly Journal I have just quoted, "the Highland Society sent the leaven of the turnip husbandry into all the glens and straths of the north, by offers of small prizes to certain Highland parishes, and the same may be said as to the growth of clover and the finer grasses. As it advanced in strength as to numbers, and to cash, attention was turned to premiums for stock; then came offers of reward to men of science to discover better implements and machines, to diminish friction, and consequently draught, such as in the threshing mill, and other parts of agricultural machinery. Still advancing in the scale of intellect and of science, premiums were offered for essays to bring to light the facts connected with chemistry and natural philosophy; and, under the auspices of the society, was set up the Quarterly Journal of Agriculture, a work which has been the vehicle of conveying so much useful information to the agriculturist, that we humbly venture to say, it ought to appear on the book-shelf and table of every farmer's parlor. After this, the great stock shows were resolved upon." At the Glasgow show in 1838, there were exhibited for prizes, 461 neat cattle, 121 horses, 274 sheep, and 47 swine; total 903 domestic animals, in 634 lots. Of the other kinds of competitors, the numbers were as follows:

For Butter,	18
" Full Milk Cheese,	15
" Skim Milk Cheese,	6
" Wool,	8
" Roots and Seeds,	13
" Implements,	28

In 88 lots.

The number of persons present at the exhibition was estimated at over 17,000, besides workmen and official people,—not one thousand of whom probably left the exhibition without carrying home with him some newly acquired knowledge in his business, or some new stimulus to improvement and industry. Not only has Scotland profited by the labors of her agricultural society, but Great Britain generally, and even the United States have been highly benefited by them. The information which that society has promulgated, has been widely disseminated among us by our agricultural journals, and has contributed not a little to the improvement of the agriculture of our country. And in England, which had been thrown into the back ground by the superior improvement of Scotch husbandry, it has within the last year, induced the formation of the English Agricultural Society, on a broad and liberal scale, which promises important advantages to English husbandry, and to agriculture generally.

As evidence of the utility of horticultural societies in multiplying and improving the products of our gardens, and in promoting rural embellishments, I would refer to the neighborhoods of Boston and Philadelphia, where societies of this kind have long existed, and to the Horticultural Society of London. In the first named cities, and their environs, the progress of horticultural improvement has been manifestly great. Many new and choice fruits, culinary vegetables, and ornamental plants, have been introduced, culture has been much improved, the markets better supplied, and prices cheapened. The London Society, although its garden has been established but about twenty years, has concentrated in it, from both continents, and from the islands of the sea embracing every clime, more than five thousand varieties of edible fruits, including fourteen hundred varieties of the apple, and seven hundred of the pear, and an innumerable number of ornamental plants, many of them before unknown in our catalogues. Its collections of pears, which embrace hundreds of recent origin, from Flanders and from France, have been already broadly spread over these states, and supply our dessert with a succession of this delicious fruit. As a corresponding member of this society, I have participated, and have enabled others to participate, in the good which it has been generously diffusing abroad. In 1825, and at subsequent periods, I have been supplied liberally with grafts of the choicest fruits which it had collected.

The great obstacles to horticultural improvement, are ignorance of the relative merits of different kinds of fruits and culinary vegetables, and of the proper modes of cultivating and preparing them for the table. The generality of country gardens exhibit but a scanty assortment of vegetable productions, and these are but badly cultivated, and often of inferior quality. The tendency of horticultural exhibitions is, to show the good and bad in contrast, or rather to promulgate a knowledge of the better sorts, of their culture and use, to excite useful competition, and to demonstrate the utility of garden culture, as a source of health, pleasure, and profit. I have had many fruits presented to me, which the donors considered of the first quality, but which I found, on comparison, to be of secondary, or inferior grade. The man who has seen or tasted only inferior fruits, may well mistake them for good ones. It is as easy to cultivate good fruits as bad ones; and no one eats so good fruits as he who cultivates them himself. It is as easy to cultivate the vergaleu as it is the choke pear; the green gage as the horse plum; and yet the difference between them, in all the qualities which we most esteem, is incomparably great. But till we can show our neighbor better fruits, he will continue to cultivate and rest content with his choke pear and horse plum.

With regard to what is termed ornamental gardening, or the cultivation of flowering shrubs and plants, there is an objection, real or affected, often made by very many people, on the ground that it yields no profit. If the great object of life was to accumulate money, without enjoying any of the comforts which it confers, save the gratification of animal appetite, the objection would be conclusive. But we are endowed with other and higher appetites than the mere brute; and Providence has every where surrounded us with suitable objects for their development, and innocent gratification. And shall we reject the proffered benefaction so kindly tendered for our benefit, because it adds nothing to our pelf? And what is there in the natural creation, better calculated to soften down the rough asperities of our nature, to awaken kind feelings towards each other, and excite reverence and love for the Most High, than a familiar acquaintance with the wonders and beauties of His vegetable kingdom. Did you ever know a misanthrope, or a miser, who was an admirer of flowers? I would not recommend the neglect of more important duties, for the culture of a flower garden: yet when there is ability or leisure, and these may be found to a greater or less extent in almost every family, a taste for floral beauties should be inculcated in the young, not only as a source of rational pleasure, but as a salutary precaution against bad companions and bad habits. The mind must be employed, and must have recreation. It is better to direct it to the works of the Creator, than to the works of man. Lord Bacon has said of the garden, "it affords the purest of human pleasures—the greatest refreshment to the spirits of man—without which buildings and palaces are but gross handiworks."

---

* Quarterly Jour. Ag. for June 1839, p. 70.

But I am forgetting myself. In my ardor to commend horticulture, for its useful, elevating, and purifying influence upon the habits and manners of society, I did not recollect that I am addressing the highly polished inhabitants of a classic city, who have long since demonstrated, in practice, the truth of the lessons I would inculcate. I will therefore dismiss this branch of my subject, and turn to the more rugged, though not less important topic of agriculture; barely adding,—

That in all endeavors to improve the condition of society, whether religious, moral, or industrial, individual efforts and example can affect but little; and hence, that in every great work of reform or improvement, the concentrated strength of many has been resorted to, and brought to a focus, by means of associations; and that the great objects of society are not likely to be promoted in a more eminent degree, by any, than by associations formed for like purposes with those which I have now the honor to address.

Being a native of this state, and having spent my early days within its borders, I can well remember the farming practices that were wont to prevail. The farm was, to use the commendatory language of that day, "suitably divided into meadow, pasture, and plough land," and each division was exclusively devoted to its object, until most of the nutritious grasses had "*run out*," in the meadow, and the plough land had become too much impoverished to bear a remunerating crop.—Many an acre was turned into "*old field*," or commons, destitute alike of natural or artificial herbage, affording scanty gleanings to half famished cattle. I beg not to be misunderstood. I am describing what *was* a bad feature in Yankee husbandry. Farming has no doubt recently undergone great improvements in Connecticut, as it has elsewhere. Yet on a fair comparison with highly cultivated agricultural districts, I believe that it will be found that the husbandry of this state, in the main, is susceptible of great improvement. The lands of Connecticut were originally rich and productive. The earthy elements remain in a great measure unchanged; the seasons are about as propitious as they were wont to be; and the lessons in improvement that have been taught elsewhere, leave little reason to doubt, that, under proper management, they may again be restored to their original fertility.

In a late tour which I made through parts of New-York and New-Jersey, I found many evidences of recent improvement, and I doubt not similar ones abound in my native state. In a part of Dutchess county, which I visited, the best farms have been sold within my recollection, with improvements and buildings, at from seven to seventeen dollars an acre. They cannot now be bought for one hundred dollars an acre; and one was sold last year at auction, without buildings, at one hundred and thirty dollars an acre. Fifteen years ago, a farm in Western New-York, of 400 acres, exhausted by bad husbandry, was bought by a Scotch farmer for $4,000. This farm has been so improved by good husbandry, that the owner was last year offered for it $40,000. He refused the offer, upon the ground that it actually netted him the interest of $60,000, or $10.50 the acre. A farm was pointed out to me in New-Jersey. which was recently sold for $7 the acre, and that was all it was said to have been worth in its then condition. By a liberal outlay in draining, it being level and wet ground, and in liming, manuring, &c. it is now considered worth $125 an acre. I went over another farm which a few years ago was bought at the same price, and which now, on account of the improvements which have been made upon it, is considered worth $100 per acre. I am informed on the best authority, that similar cases of the rapid increase in the products and value of farms, consequent upon an improved system of management, are to be found in Pennsylvania, Delaware, and Maryland. Although these cases are isolated ones, they nevertheless serve to show the practicability of vastly increasing the value and products of our exhausted lands.

Among the causes which have essentially contributed to the deterioration of our lands, and the consequent depression of our agriculture, I consider the following as prominent:

Ignorance of the *principles* of agriculture;

The want of a sufficient outlay in the management of our farms; and

The low estimation in which the employment has been held by all classes, including farmers themselves.

Agriculture has too generally been considered a business requiring mere physical power, with which the principles of natural science had little or nothing to do. To plough, sow, and gather the crop, has been the general routine of farming operations, regardless of the poverty which our practice was inflicting upon the soil and upon our children. Like the reckless heir of wealth, we found ourselves in possession of a treasure; and without inquiring for what purpose it came into our hands, or realizing our obligations to husband and preserve it, for others, we have squandered it lavishly, through our ignorance or our folly. True, we have been occasionally admonished of our error, by the schoolmen; who, wrapped in abstract science, and knowing little practically of its application to husbandry, have as often tended to confuse and mystify, as to enlighten and instruct. Hence the prejudice which has arisen against book-farming. But science and art are now uniting their labors, and are deriving mutual aid from each other, on the farm, as they have for some time been doing in the manufactory and in the shop of the artizan. A new era is dawning upon the vision of the farmer; new light is illuming his path, and a new interest and new pleasures are urging him on to improvement. He begins to study the laws which Providence has ordained for the government of improved culture, and he finds, in their application to his labors, the means of increasing profits and high intellectual enjoyment. And the more he studies and is guided by these laws, the more does he become satisfied of former errors, and of his comparative limited sphere of usefulness. Science is probably capable of rendering more important services to husbandry than to any other branch of labor, and presents a wider field of useful study to the cultivator of the soil, than to any other class of society.

The deficiency in farming capital, or rather the stinginess with which capital is employed in improving and maintaining the condition of our lands, is another cause of declension in the profits and character of our agriculture. The farmer is too prone to invest his surplus means in some new business, or in adding to his acres, instead of applying them to increase the profits of his labor and the products of his farm. He either works more land than he can work well and profitably, or he diverts to other objects the means which would yield a better return if applied to the improvement of the farm. He is apt to consider twenty or thirty dollars an enormous and wasteful outlay upon an acre of land, or upon a choice animal; and yet the interest of this outlay will be ten times paid by the increase of crop or the increase of the animal; and in most cases the principal also will be returned to him in the course of two or three years. Many of the most thriving farmers in southern New-York, New-Jersey, and Pennsylvania, make a quadrennial expenditure of twenty dollars or more to manure an acre; and it has become a maxim with them, that the more the outlay for manure, the greater the nett profit of their lands. But it is not the outlay for manure alone, that demands a liberal expenditure of capital. Good seed, good farm stock, and good implements, are all essential to the economy of labor, and to neat and profitable farming. And I think it will appear from the cases I have quoted, that in many locations, capital may be very advantageously employed in reclaiming wet and marshy grounds, generally rich and the most productive when laid dry.

When our cattle grow lean and threaten to disappoint our hopes of profit, we do not hesitate to impute the evil to the want of food, or to inattention in the herdsman. And if we are prudent managers, we at once graduate our stock to our food, knowing that one well fed animal is of more value in the market, than two animals that carry but skin and bones, and take care that the food is properly fed out. When our crops become lean, we need not hesitate to ascribe the decrease in product to like causes—want of food, or want of attention in the farmer; and prudence and profit in like manner require, that our crops, like our animals, should be limited to the food and labor which we have to bestow upon them. In other words, an acre well manured and well worked, will be found to be more profitable, than four poor acres badly worked.

I may here be asked, from whence are to be obtained the vast supplies of manure requisite to manure our old lands? I answer, from a multiplicity of sources around us, from every animal and vegetable substance within our reach. Nothing that has once been part of an animal or a vegetable, but can be converted into corn, grass and roots. I think I may assume as facts that upon an average, not half the manure is saved upon our farms that might be, and that this moiety is half lost before it is applied to the soil. Every horse, ox or cow, wintered upon the farm, if well fed, and littered with the straw, stalks, &c. of the crop, should make from six to ten cords of good manure. Dr. Coventry, late professor of agriculture at Edinburgh, estimated that the straw of an ordinary acre of grain, computed at 21 cwt. may be converted by the urine and liquids of the stables and cattle yards, into three and a half tons of manure; that meadows that cut one and a half tons of hay will give four tons of manure; clover, the first year, six tons, and the second year, five and a half tons per acre; and that with the extraneous substances which may, with due care, be collected without expense from the roads, the ditches, the ponds, and from refuse of every kind about the house and premises, the acreable amount should be amply sufficient for a full supply of manure once during every course of the four year system of husbandry.—Arthur Young, with 6 horses, 4 cows, and 9 hogs, which consumed 16 loads of hay and 29 loads of straw, obtained 118 loads of manure, 36 bushels to each; and from 45 fatting oxen, well fed and littered, 600 tons of rotten manure. But an American lawyer,* and an excellent practical farmer withal, has gone beyond these estimates. I visited his farm a few weeks ago, which lies upon the sea shore. It consists of about 200 acres, most of which was in a course of crops. The crops of the season had all received an ample supply of manure, as their appearance indicated—and yet I was shown masses of well prepared compost, in reserve, consisting of yard manure peat ashes, peat earth, sea weed, and fish—estimated at twenty-five hundred loads—*all produced upon his own farm.*

The third obstacle to agricultural improvement, which I propose to notice, is the subordinate rank to which this employment has been consigned, and to which the farmers themselves have contributed, by a want of respect for themselves and respect for their vocation. The wholesome habits of society have been so broken up, by the civil and political convulsions of the age, and the inordinate thirst for acquiring wealth and fashionable consequence, through mercantile and other speculations, that honest productive labor has been thown entirely into the background, and considered not only ungenteel, but menial and servile. Yet I venture to lay down this proposition, that he who provides for the wants and comforts of himself and family, and renders some service to society at large, by his mental and physical industry, performs one of the high duties of life; and will ultimately be rewarded in the conscious rectitude of his life, by a greater measure of substantial happiness, than he who makes millions by fraud and speculation, to be squandered in extravagance or wasted in folly, by his children or grand-children. The revolutions that are constantly taking place in families, sufficiently admonish us, that it is not the wealth we leave to our children, but the industrial and moral habits in which we educate them, that secures to them worldly prosperity, and the treasure of an approving conscience.

The farmers, I have remarked, share in the errors of the day. Not content with the gains which are ever the reward of prudent industry, and which might be greatly increased by the culture of the mind,—nor content with one of the most independent conditions in society, hundreds and thousands of them seek other and new employments, and some of truly menial character, to get rid of labor, the greatest blessing to man, and to raise themselves in the imaginary scale of fashionable society. And if they cannot participate themselves in this imaginary greatness, and it is seldom any thing more than imaginary, they are anxious to inflict the evil upon their posterity,—to rear their sons to the law, the rail-road to office,—to political power and turmoil; to make them merchants, a useful, but greatly overstocked business, or to place them in some other genteel employment, which shall exempt them from the toils of labor, the salt that best preserves from moral corruption.

Mistaken men! What class in society have within their reach so many of the elements of human enjoyments—so many facilities for dispensing benefits to others—one of the first duties and richest pleasures of life—as the independent tillers of the soil? "The farmer," says Franklin, "has no need of popular favor; the success of his crops depends only on the blessing of God upon his honest industry." If discreetly conducted on the improved principles of husbandry, agriculture offers the certain means of acquiring wealth, and as rapidly as is consistent with the pure enjoyments of life, or with the good order and prosperous condition of society.—Agriculture is the golden mean, secure alike from the temptations of mushroom opulence, and the craven sycophancy and dependence of poverty. "Give me neither poverty nor riches," was the prayer of the wise man of Scripture "lest," he added, "lest I be full and deny thee, and say, who is the Lord? or lest I be poor, and steal, and take the name of my God in vain."

When we consider that agriculture is the great business of the nation—of mankind; that its successful prosecution depends upon a knowledge in the cultivators of the soil, of the principles of natural science,—and that *our* agriculture stands in special need of this auxiliary aid,—we cannot withhold our surprise and regret, that we have not long since established professional schools, in which our youth, or such of them as are designed to manage this branch of national labor, might be taught, simultaneously, the principles and practice of their future business of life, and on which, more than any other branch of business, the fortunes of our country, moral, political, and national, essentially depend. We require an initiatory study of years in the principles of law and medicine, before we permit the pupil to practice in these professions. We require a like preliminary study in our military and naval schools, in the science of war and navigation, ere the student is deemed qualified to command. And yet, in agriculture, by which, under the blessing of Providence, we virtually "live, and move, and have our being," and which truly embraces a wider range of useful science than either law, medicine, war or navigation, we have no schools, we give no instruction, we bestow no governmental patronage. Scientific knowledge is deemed indispensable in many minor employments of life; but in this great business, in which its influence would be most potent and useful, we consider it, judging from our practice, of less consequence than the fictions of the novelist. We regard mind as the efficient power in most other pursuits; while we forget, that in agriculture, it is the Archimedean lever, which, though it does not *move*, tends to *fill* a world with plenty, with moral health, and human happiness. Can it excite surprise, that under these circumstances of gross neglect, agriculture should have become among us, in popular estimation, a clownish and ignoble employment?

In the absence of agricultural professional schools, could we not do much to enlighten and raise the character of American husbandry, by making its principles a branch of study in our district schools? This knowledge would seldom come amiss, and it would often prove a ready help under misfortune, to those who had failed in other business. What man is there, who may not expect, at some time of life, to profit directly by a knowledge of these principles? Who does not hope to become the owner, or cultivator of a garden or a farm? And what man, enjoying the blessing of health, would be at a loss for the means of an honest livelihood, whose mind had been early imbued with the philosophy of rural culture—and who would rather work than beg?

---

* W. A. Seeley, Esq. of Staten Island.

An early acquaintance with natural science, is calculated to beget a taste for rural life and rural labors, as a source of pleasure, profit, and honor. It will stimulate to the improvement of the mind—to elevate and to purify it,—to self-respect, to moral deportment. And it will tend to deter from the formation of bad habits, which steal upon the ignorant and the idle unawares, and which consign thousands of young men to poverty and disgrace, if not to premature graves. A knowledge of these principles, to a very useful extent, can be acquired with as much facility in the school, or upon the farm, as other branches of learning. Why, then, shall they not be taught? Why shall we withhold from our agricultural population that knowledge which is so indispensable to their profit, to their independence, and to their correct bearing as freemen? Why, while we boast of our superior privileges, keep in comparative ignorance of their business, that class of our citizens who are truly the conservators of our freedom? I know of but one objection:—the want of teachers. A few years ago, civil engineers were not to be found among us. The demand for them created a supply. We have demonstrated that we have the materials for civil engineers, and that we can work them up. We have materials for teachers of agricultural science, which we can also work up. Demand will always ensure a supply.

The enumeration of the foregoing obstacles to agricultural improvement, sufficiently indicates the means which will be efficient in removing them. The means consist, so far as I now propose to notice them—

1. In giving a *professional* education to the young farmer, which shall embrace the *principles* and the *practice* of the business which he is designed to follow in life, and

2. In diffusing more extensively among those who have completed their juvenile studies, and are better fitted to profit by the lessons of wisdom and experience, a knowledge of the same principles, and of the best modes of practice which these principles inculcate, and which experience has proved to be sound.

We have professional schools in almost every business of life, except in the cultivation of the soil, one of the most important and essential of them all, and one embracing a larger scope of useful study in natural science, and in usefulness to the temporal wants of the human family, than any other. The policy of monarchs, and of privileged orders, has been to repress intelligence in the agricultural mass, in order to keep them in a subordinate station. But neither the policy nor the practice should be countenanced by us. Our agriculturists are our priviledged class, if we have such. They are our sovereigns, because, from their superiors numbers, they must ever control our political destinies, for good or for evil. And the more intelligent and independent we can render them, the more safe we make our country from the convulsions of internal feuds, and the danger of foreign war.

I put the question to fathers—Would you esteem that son less, or think him less likely to fulfil the great duties of life, who had been educated in a professional school of agriculture, with all the high qualifications which it would confer for public and domestic usefulness, than him who had been educated for the counter, the bar, or other high professional callings? On which could you best rely for support and comfort in the decline of life? Nay, I will venture to carry the appeal farther—to the discriminating judgment of the unmarried lady—Would you reject, as a partner for life, the student of such a college, coming forth with a sound mind, deeply imbued with useful knowledge, and a hale constitution, invigorated by manly exercise, whose cares and affections were likely to be concentrated upon home and country, and whose precepts and examples would tend to diffuse industry, prosperity, and rural happiness around him? The father's response would be, I think, an unhesitating no, to the first question; and the lady's after due deliberation, I verily suspect, would be a half articulate amen! I pretend not to the spirit of prophecy, yet I venture to predict, that many who now hear me, will live to see professional schools of agriculture established in our land, to see their utility extolled, and to be induced to consider them the best nurseries for republican virtues, and the surest guarantee for the perpetuity of our liberties. They should be established—they will be established—and the sooner they are established the better for our country.

To those who have passed to manhood, and who have made up their minds, from necessity or from choice, to till the ground, the means of improvement—of studying the principles of their business—and of becoming acquainted with the most approved and modern practices in husbandry,—the opportunities of acquiring useful knowledge, are abundant and cheap. One of these means, and a valuable one, is proffered him through the exhibitions and publications of these societies. Another is the perusal of books upon agriculture and rural economy, which should form a part of social and rural libraries. And another facility of acquiring this useful knowledge, is afforded by the agricultural periodicals of our country, which, besides containing much that is instructive in the philosophy of farming, are a record of the best modes of practice, and of much that is new and important, in the various departments of rural and household labor. A volume of the Cultivator, of which I can speak with accuracy, contains about as much matter as five or six volumes of the popular novels of the day, and twice as much as four numbers of our literary quarterly journals. The price of the Cultivator is one dollar per annum. I verily think, that if the farmer would divide his patronage between political and agricultural journals, he would be a manifest gainer, in his fortune and in his family—would be more happy in his business, and domestic in his habits—a better manager, and a more useful citizen.

Time will not permit me to go into the details of modern improvements in husbandry. These improvements are great, and afford the brightest hopes to the philanthropist and the patriot. No one who can carry back his memory forty years, can withhold his wonder at the astonishing improvements which have in that time been made in the manufacturing and mechanic arts, by reason of the aids of science; and those who can scan the future, will have no less reason to rejoice, in the anticipated advantages which are in prospect, from an improved culture of the mind and the soil, consequent upon a better system of education to the agricultural population, and the general diffusion of useful knowledge, which is likely to result from it.

I will merely further remark to the farmer, that if he would prosper in his business, he should study, practice and adopt, the better system of husbandry which is abroad in the land, and which has already greatly profitted thousands, so far as his soil and circumstances will permit;—that he should drain his wet lands, economize his manures, and apply them with judgment;—to cultivate well, what he does cultivate;—to alternate his crops;—to extend his root culture; to increase and improve his stock, as the products of his farm will permit;—and to substitute fallow crops for naked fallows.

In conclusion, gentlemen, permit me to express my hearty wish, that success and honor may crown your efforts to improve the condition of your country, industrial and moral, associate benefits almost as intimately connected, as cause and effect—and that you may long live to enjoy the blessings which are promised to him who truly loves his neighbor, and reveresand worships his God.

CORRESPONDENCE.

Tropical Florida.

[Lat. 24°, 48′, N. long. 80°, 55′ W.]
Indian Key, T. F. 12*th Nov.* 1839,
[Ther. 80° Fahrenheit.]

To Jesse Buel, *Editor of the Cultivator,*
Albany, New-York.

Sir—As none of the Cultivators for the last year were received until all the numbers came together a few days ago, via the remote part of Key West, I could not, of course, previously observe in your February No. at p. 187, the *paragraph* in which my *name* is connected with opposition to the Mulberry-selling speculations and silk producing calculations of the Northern States. Permit me then to repeat, that *my* written opinions of the silk business in the Northern States, are conformable to *your* printed opinions on the same subject. I have always maintained, that in those wintry regions this rural industry can only become a collateral branch of common farming—a temporary occupation of household industry—in short, what it has been in Connecticut ever since its first introduction, fifty years ago. I have, therefore, always sustained the positions, that the advantages of the *extension*, over the Northern States, of the combined propagation of Mulberry plants and the bona fide production of raw silks, should not be calculated on the false hypothesis that this new branch of rural industry would yield greater profits than the common products of common farms; but that the benefits should be estimated from the important facts, that the Mulberry trees can best be grown on the *poorest*, and otherwise least productive, *lands;* and the raw silk can best be produced by the *feeblest*, and otherwise least productive, *hands*. As a temporary collateral branch of farming, then, I admit that it may be desirable to employ six weeks annually in the production of raw silk by the *feeblest hands* on the *poorest lands* of even the Northern States. But the agricultural statesman for the whole country, will readily convince himself of the relative superiority of the *old* Southern States for the profitable production of raw silk as a *collateral branch* of their planting industry. The great superiority of the old Southern States over the old Northern States, and even over the new Western States, is easily shown by the irrefutable facts, that their vegetating seasons are much longer; that their poorest lands are much cheaper, and that their unproductive hands are more numerous and more controlable. In other words, it can be thus demonstrated that the old Southern States can afford to sell raw silk at two dollars and fifty cents per pound, and yet *gain* five dollars per acre *nett profit* for their *poorest*, unproductive lands, and will also gain fifty cents per day *gross wages* for their feeblest unproductive hands. As a temporary collateral branch of planting, then, I contend it will be much more desirable to employ twelve weeks annually in the production of raw silk by the feeblest hands on the poorest lands of the old Southern States. But, Sir, in relation to the permanent production of raw silks in the United States, the most important facts which should again be presented to the whole community, are those irrefutable facts by which I have long since demonstrated the *superlative superiority of South Florida for the profitable production of raw silk!* 1. That it enjoys a tropical climate peculiarly favorable to human health and to vegetable growth the whole year round. 2. That the morus multicaulis, being a tropical plant from the Tropical Phillippine Islands, has hence returned to its native climate on the tropical Florida Keys. 3. That in this tropical climate, the Manilla Mulberry is an evergreen tree, which does reproduce its bulky leaves, and which can be propagated by its numerous buds in every day of every year. 4. That hence, in this tropical climate, the silk worms can be fed, and their silk cocoons can be spun on every day of every year. Very respectfully, your obedient servant. HENRY PERRINE.

P. S. I still repeat that the morus multicaulis is a splendid humbug; but I shall rejoice at its continuance, provided its energies be exerted *in the only district* of the Union where the greatest possible number of plants can be propagated in the least possible time, and where the greatest possible quantity of silk can be produced at the least possible expense. If only ten of the wealthiest speculators had been established two years in these Florida Keys, the whole United States would have been roused by their clamorous proclamations of *certified* facts of their infinite superiority for the continual propagation of Mulberry buds, for the continual reproduction of Mulberry leaves, and consequently for the continual feeding of silk worms, and for the continual production of raw silks!!

Comparative contrast of the opposite climates of Southern Mississippi and Southern Florida.

1838.—*Natchez, Miss.*—Clear days, 43; cloudy 192; rainy 93; foggy 27; hazy 5; snowy 3; sleety 2.—Hottest day 94°; coldest day 18°, or 14° *below* the freezing point of Fahrenheit's scale.

Indian Key, T. F.—Clear days 314; cloudy 15; rainy 36.—Hottest day 90°; coldest day 50°, or 18° *above* the freezing point of Fahrenheit's scale.

Add for Indian Key the fact, that the *greatest* change in one *month* was 33°, and the *greatest* change in one *day* was 14°, and you will readily conceive the incontrovertible reality, that Tropical Florida enjoys the most delightful weather, with the most healthy climate in the whole United States.

You know that the slanderous charges of deadly sickness against South Florida are solely derived from the detracting reports against the only port of Key West. But supposing that near the southwestern extremity of this reef at the remote island of Key West, the village itself should be a sickly locality at all seasons of every year; nevertheless, you will perceive that it is *separated* by seventy-eight miles of latitude and longitude in the open sea from the *nearest* point of the *healthy mainland* at Cape Sable! HENRY PERRINE, M. D.
at Indian Key, Tropical Florida.

Manufacture of Maple Sugar.

Rutland, Vt. 24*th Nov.* 1839.

To the Conductor of the Cultivator,
Albany, New-York.

Sir—Understanding that Mr. Henry Mussey, of this town, is a competitor for a premium offered by you in the month of April last, "for the best sample of ten pounds of maple sugar, produced by household process," the arrival of whose sample was announced in the September number of the Cultivator, and that his standing in this vicinity for reputation, truth and veracity, should be vouched for by some person known to you, I have great satisfaction in giving my testimony in behalf of Mr. Mussey, as being one of our best farmers—one of our most substantial and reputable citizens—and whose representations as to his method of manufacturing the sugar in question, or, indeed, upon any other subject, would receive in this community, the most implicit credit.

I am, very respectfully, your obd't serv't,
JESSE GOVE.

Rutland, Nov. 26, 1839.

Mr. Jesse Buel—Sir—As a competitor for the premium offered in the April number of the Cultivator, sometime in August I sent your deceased father ten pounds of maple sugar, the receipt of which was acknowledged in the September number, with a request for the mode of manufacture and the estimated expense, which I will endeavour to give.

1. Scald the buckets clean.

2. Boil the sap as soon as possible after running from the tree, in the old burning process, that is, in fireplaces or between logs, (although we endeavour to burn as little as we can, and wash the kettles once a day,) down to thin syrup.

3. Settle over night, and draw off clear.

4. Cleanse with a pint of milk to 50 lbs. sugar, and sugar off in the common way, leaving it so thin that some molasses shall stand on the sugar: and,

5. After drawing molasses twenty-four hours through a hole in the bottom of the tub, (our tubs hold from 100 to 300 gallons,) spread a double cloth over the top and lay on clay about two inches thick, of the consistency of thick milk porridge; after three or four days, take off the clay, and if the sugar is not sufficiently

white, wet up the clay and lay on again, which may be repeated till the sugar is as white as loaf, (the sample sent was clayed only once.) This will whiten about one-third of a tub, say two and a half feet deep, which may be taken off, and the rest clayed as before.

I estimate the expense of raw sugar at five cents per pound, and of clayed at eight cents, in good seasons like the last, when from 300 trees we made 1500 lbs. raw sugar.

If the premiums in the April number are offered by any society, please to present the sugar to them; if they are only the private offers of your deceased father, present it to his afflicted family, as a testimony of the high respect in which the name of Jesse Buel is held by myself, as well as the agricultural community.

Respectfully yours, &c.
HENRY MUSSEY.

Durham Cattle.

It has been conjectured by many, that the apparent high prices at which the "Improved Durham Short Horned" cattle have been held, could be maintained but for a few years. This has been the burthen of the song of those who were desirous of possessing them, but were unwilling to pay but a trifling sum over the price of the common cattle of the country. And if perchance, a farmer who has a little more enterprise and liberality than his neighbors, should *venture* to purchase a bull of an improved breed, at one or two hundred dollars even, he is pretty sure to incur the ridicule and sneers of his less enterprising neighbors, instead of encouraging him and benefitting themselves by the introduction of a superior breed of cattle.

This feeling, I am happy to say, is losing ground, and the importance of improving our cattle is more apparent. Several Durham Bulls were purchased in this vicinity last spring, ranging from one hundred to four hundred dollars each, and taken into Vermont, which I am informed, cleared themselves the first season. This is as it should be.

Now, I will venture to assert, that the owners of the heifer calves from either of these bulls, and a common cow, could not be prevailed upon to part with one short of from twenty-five to thirty dollars, when they would jump at five dollars for one of the common breed.

Some have been patiently waiting, with an idea that the country would soon be filled with them, and the prices would fall; but from some late sales made by auction in this country, as well as in England, it is feared they will have to wait some time longer, before they will be gratified with an opportunity.

In a late (October) number of the "Farmers' Magazine," I observed the sales, in September last, of the stock of three noted breeders. The first was the stock of the Earl of Carlisle, at Castle Howard, near York. The attendance of gentlemen from all parts of the country was very numerous, and the sale excited much attention amongst breeders, graziers and others from the well know superior quality of the stock always raised at Castle Howard.

The prices paid for cows and heifers, forty-seven in number, ranged from 20 to 320 guineas each, and averaging $310. There were twenty-four bulls and bull calves, which ranged from 16 to 120 guineas, averaging over $226 each. The whole proceeds of the sale were near $20,000.

The second sale immediately after the above, was of Mr. Henry Edwards, of Market Weighton, and the sales effected, (above £50,) were for eight cows from 61 to 300 guineas each; averaging over 110 guineas, and ten calves from 20 to 100 guineas, averaging over 39 guineas each.

The third sale was the property of John Colling, Esq. of White House, near Gretna Bridge, and, says the writer, "a more splendid display of these beautiful animals has rarely been witnessed. The animals were of a superior order, both as regarded symmetry and condition, and the prices will fully prove their superiority."—Twenty six cows, heifers and calves, ranged from £18 to £200 averaging £71 each. Seven bull calves ranged from £13 to £82, averaging over £38 each.

From the above sales, we are led to believe, that the "Improved Durham Short Horned" cattle maintain pretty fair prices at the present time in England; and in this country, this description of stock appears to be still on the rise. This is owing to the great demand for thorough-bred animals in all the Western States, and the present impossibility of supplying that demand by the natural increase, of the number of animals now in this country.

At a late sale of Wm. A. Warner, Esq. of Kentucky, his bull Frederick, was struck off at $1,625. Several of his cows sold at from $900 to $1,100.

A sale of Durham Short Horned Cattle recently took place at Powelton, Pa. where eight cows, heifers and calves were sold at auction, averaging $458 each; the highest price paid being $610, and the lowest was for a calf only ten days old, at $200.

I am also advised by a late number of the "Franklin Farmer," that Mr. L. Sherley, of Louisville, Ky. lately sold at private sale, his imported Durham Bull "Velocipede," at the high figure of $1,500, after taking premiums in plate the past fall, of the value of $105.

The same gentleman also sold his imported roan calf, "Liverpool," for $1,000. He was exhibited only at the Jefferson County Fair this fall, where he carried off the $20 premium, as the best yearling calf.

It is now about thirty years since the Messrs. Collings' sale of Durham Short Horned Cattle took place in England, when the famous bull Comet, was sold under the auctioneer's hammer, for 1,000 guineas, and some of their cows sold from 300 to 410 guineas.

That these extraordinary high prices will be maintained, I will not contend; but that they will command fair prices for some years to come, will be readily admitted by those who are best acquainted with their merits.
C. N. BEMENT.

Three Hills Farm, December, 1839.

Devonshire Cattle.

Mr. Buel—Sir—It appears to be the general opinion among the northern farmers, that the Durham cattle are not adapted to the climate, that the pastures are not sweet or rich enough, and that the winters are too cold and severe. Why would it not be a good plan to buy some other breed that will keep on short pasture and stand our severe winters?

The Devonshire cattle I think will suit those persons whose opinion is against the Durhams. I do not say that the Durhams will not do, for I think I have seen as fine cattle of that breed in some of the northern counties as will be found: they were not entirely full blooded, but were bred up from the native stock, which is the only true way to get a good breed of cattle adapted to our climate.

Our native cattle are hardy and can stand our cold and rigorous winters, and their produce from an improved bull, will, I think, do better than the pure bloods.

The Devons are said to be a hardy race, are classed as middle horns, and celebrated for their beauty, activity at work, and aptitude to fatten. They are of a mahogany colour, white horns, the nose and circle around the eye yellow.

For working cattle they are allowed to be the most active, having a quick walk, and in a light cart or wagon will trot at the rate of four or five miles per hour.—This is not requisite, but it shows that they can use their limbs to good advantage. I have seen a yoke of them that drew a large load of grain nine miles, as quick as a span of horses would.

The disposition of the Devons to fatten stands almost unrivalled, and in a given time, with less food, they will acquire more flesh than most any other kinds. They are by no means a large sized cattle, the bulls are smaller than the ox, and the cows still smaller than the bull.

The cows for milk are considered inferior to some other breeds, but the quantity they give is richer in proportion to that of other breeds, and I believe were they thoroughly tested, they would rival almost any other breed in quantity and quality.

I have seen on the farm of C. N. Bement, at Albany, some fine specimens of this breed, also some half Devons, and half Durhams which were really beautiful cattle. The half bloods resembled the Devons in color and form, except being broader across the hips than the pure Devons, thus making up that deficiency which has so long been an objection by the amateurs of fine stock.

Mr. Rotch, of Butternuts, has imported within a year a couple of fine heifers of this breed, and I think much credit is due him, as they were procured at great expense to benefit the stock of this country.

Some other gentlemen have fine specimens of this stock, and it is gratifying to look into their barn-yards, and see the improvement that has gradually crept in of late years.

Public opinion has great weight with many people, and when a prejudice is once formed it is hard to overcome it. I am in hopes, however, that people will soon begin to think and act for themselves, and through the medium of agricultural papers let the world know what they have done, and by so benefitting one another, we may soon begin to look up and mend our old ways.
PHELIM.

December, 1839.

Rohan Potatoes—China Tree Corn.

Gustavus, Trumbull co. O. Nov. 13, 1839.

J. Buel, Esq.—Sir—When in New-York last spring, I purchased of Mr. G. Thorburn, a few Rohan Potatoes, and on the 29th of April planted *two* of them, weighing eleven and a half ounces.

I cut them into 30 pieces, leaving but one eye in each piece, and planted them in 12 hills, 3 feet apart each way. On the 16th of October, I dug from those 12 hills 175 potatoes, measuring two bushels, heaped measure, and weighing 118½ pounds.

I cannot say that any extraordinary means were used either in planting or hoeing. I put manure in the hill before planting, and hoed them three times, and I believe had the season not been unusually dry, the product would have been greater. As it is, if you think the notice of it worth a corner in the Cultivator, you are at liberty to give it.

I planted an ear of the China Tree Corn on the 15th of May, but it did not get ripe. I am not, however, entirely discouraged, as the Dutton Corn planted at the same time, in the same neighborhood, was also injured by the same early frost. The superior appearance, extraordinary growth, and great number of ears to the stalk and hill, induces me to think of giving it another trial.

I am fully persuaded, that if it *will* ripen in this climate, it will yield more abundantly than any other kind of corn.

Respectfully yours, &c.
GEORGE HEZLEP.

Staples's Patent Straw-Cutter,

Is a new invention on a new principle, for which the subscriber has received a patent.

Convinced of the great economy in cutting up every description of rough feed to be fed out, and the importance of a good and efficient straw-cutter to every farmer, the subscriber turned his attention to inventing one for his own use, free from the many objections to the various implements of this kind, and he has succeeded in perfecting a machine which is pronounced by good judges to be the end of improvement in these things.—It is as perfectly simple, durable and efficient a machine for cutting up every description of rough feed, as can be asked; the wear of any part will not prevent its doing its work well. This machine has two knives, which from a drawing motion peculiarly adapted to cutting, will cut well without that keen edge that all other straw-cutters require, and will therefore want less grinding or sharpening, and for this purpose they are very easily taken off and replaced, as no screws are attached to them, and no nice fitting on required. There are two bed shears which support the feed on each side as it is cut by the knives, and not a straw will ever escape uncut, or be bruised or mashed off, let the knives be dull or sharp. These machines require little power, and are easily made or repaired by any common workman.

To try how much could be cut in a given time with one of these machines, one hundred pounds of sheave oats were weighed out, and they were reduced to pieces in two minutes and a half.

These machines are manufactured at the subscriber's shop, near Lynchburg, Va. price $20.

To persons disposed to purchase the right of making and vending these machines, they offer great inducement, as an examination of them will not fail to induce every one to purchase who is in want of a straw-cutter; and to introduce them abroad, the rights for the different states or counties will be sold low; and for the same reason, where three or more machines are ordered, a considerable discount will be made, in proportion to distance, and the machines delivered in Lynchburg.

For further information, address the subscriber at Lynchburg, Va. WILLIAM A. STAPLES

Lynchburg, Nov. 25, 1839.

Rohan Potatoes.

Auburn, Nov. 14th, 1839.

Jesse Buel—Dear Sir—While reading the Franklin Farmer, (a paper published at Frankfort, Ky.) I observed the following notice or inquiry:

"Rohan Potatoes.—If any of our readers have been successful in the cultivation of this root, we should like to hear from them. We got a very large one from Boston, which we planted with some of our friends. We planted two hills in excellent soil, worked them well, but did not get a *tuber* as big as a pin head. One of our friends, from one hill, got five little things, neither as big as a partridge's egg; while he says, 'our common potatoes yielded prodigiously, the finest and largest we ever saw.'"—*Franklin Farmer, Vol. III. No.* 11, *p.* 83.

With respect to this, I should like to ask, (if this should chance to meet the eye of the Franklin Farmer,) whether there might not have been some mistake in the kind of potato? (as there probably has been here in respect to the Chinese tree corn,) or if the reproducing qualities of the potato might not have been injured in its conveyance from Boston to Frankfort? for it is generally believed that good old Kentucky is celebrated for its fertility of soil.

Last spring I purchased four Rohan potatoes from Walker's seed store, Schenectady. These, with a few other small ones given to me by Prof. Jackson, of Union College, I planted about the middle of April, and dug from them, the first of October, eight and a half bushels. From one of them, which was kept separate from the rest, I dug two bushels, the tubers in general being very large, none of them as small as our common potato; it was said by a gentleman who saw them, that they were larger and fairer than most exhibited in New-York.—The potato I planted had twenty-two eyes, I put them in eleven hills, three feet apart.

A gentleman residing in this vicinity raised *three bushels* from one potato, sent to him by a relation in Rochester.

I should also, in connection with this, like to ask, whether it is profitable to spade up a garden in the fall and let it lay till spring, or wait till spring, then to do it? And whether a difference of treatment should be used on a dry sandy, and a dark clay, soil? The reason of my inquiry is this—while spading a week or two since a garden of dry sandy soil, I was asked why I did it now? I answered, it was generally the custom to spade a garden in the fall. He said he did not believe the custom was in accordance with good policy, and did not believe that those who acted thus could give a reason for it to sustain the position. I should like, furthermore, to ask, whether it is preferable to put manure (not entirely fermented,) on the ground after spaded in the fall, and let it remain till spring, or put it on in the spring?

Should this meet your approbation, an insertion in your paper would be exceedingly gratifying, with information respecting the inquiries.

Respectfully yours,
HENRY H. HOPKINS.

Ruta Bagas and Sugar Beets for Hog-Feed.

About the 15th of November, 1838, I shut a pig by itself that weighed 82lbs. and fed it on boiled ruta bagas, with about a peck of bran mixed with a bushel of the ruta bagas. When it had been fed on this food 58 days, it was weighed and found to have gained 60 pounds.—I afterwards, during the winter, fed the same pig and other hogs, for a few days, with ruta bagas boiled and mixed with bran, the mixture allowed to get pretty sour; and they increased in weight very slowly. I then fed the same animals with sugar beets boiled and mixed with bran as were the ruta bagas, and allowed to sour; they ate considerable of it, but did not devour it greedily. After feeding them with this food a few days, I perceived they lost flesh, and probably would have died, if the same food had been continued; yet I have no doubt either of these roots will fatten hogs very well if fed before they sour. The principal part of the nutricious properties of these roots consists of sugar, and consequently the first fermentation changes it to alcohol and carbonic acid gas.

S. W. FOSTER,
of Scio, Michigan.

Albany, Nov. 20, 1839.

EXTRACTS.

[*From the Genesee Farmer, Nov.* 30.]

Caution to Postmasters.

We find it necessary to republish our exposition of the conduct of J. E. Force, as we learn that he is flooding the country with his spurious Prospectuses, in the hope, probably, that they will fall into the hands of many persons who will not see our statement, and he thereby be enabled to obtain *advance payments* on the credit and reputation of the genuine Genesee Farmer. It therefore becomes necessary to give our expose a more extensive circulation, that the friends of the Genesee Farmer, and the public generally, may be on their guard against the gross imposition attempted to be practised upon them, in thus sending out (with my papers in some instances) a Prospectus purporting to come from my office. As a specimen of the views taken of the matter, by those who understand it, we publish the following extract of a letter from one of the most distinguished advocates of the Agricultural interest in Western New-York. He says:—"What an infamous scheme your letter has exposed. I am glad they started so early, as I think your exposure will put on the cold water effectually for a time. The project will probably revive again in some form, but hardly, I imagine, in one so rascally. You may use my name in any way you think best, to counteract the scheme. I should have expected nothing different from Goodsell; and Force, I think, could have been only a tool. I have read your expose, and, though pointed, I do not think the language any too strong to properly characterize such conduct. 'Connected with the Genesee Farmer for a year,' Force says. Some years since, at a show in New-York, a company of gentlemen and ladies were admiring a beautiful volume—its printing, binding, &c. when a miserable fellow came up and claimed the credit of its execution. The assertion was doubted, and when pressed to tell what part of its execution belonged to him, he stammered forth at last,—'I made the paste!' Such is pretty much the part Force has performed in the office of the Genesee Farmer."

Gross Imposition.

I have just seen a Prospectus, headed "Genesee Farmer Extra, 1839," for what purports to be a "new series" of the "Genesee Farmer,"—"N. Goodsell and J. E. Force, editors, and J. E. Force, proprietor,"—a large number of which, I am informed, have been printed in this city for circulation abroad. Justice to the public, as well as a regard to the good name of myself and paper, seem to render it obligatory on me to caution the public against this spurious Prospectus, which has been got up by a young man not yet of age, who has been employed in my office, for a year past, to keep my accounts and mail my papers. Had not Force and Goodsell, however, placed *the name of the Genesee Farmer* at the head of their Prospectus, thus giving it the character of an Extra issued from my office, and made statements which are altogether destitute of truth, I should not probably have deemed it necessary to have noticed their efforts, nothwithstanding the dishonesty manifested in filching the name of my paper, and the perpetrator at the same time appropriating to himself the confidential knowledge of my business, books and correspondence, while yet in my employ. A simple statement of facts will serve to show whether the public will be likely to receive in return for their money, a paper of the high character of the present Genesee Farmer, or even any paper at all for any length of time. J. E. Force, who represents himself as proprietor, claims "a year's connection with the Genesee Farmer," from which the public might infer that he was or had been either one of its editors or proprietors. It is proper, therefore, to state the extent of his "*connection* with the Genesee Farmer," which consisted in his being employed in the office the last year to pack and carry the papers to the Post-Office at a salary of five dollars and a half a week. This Mr. Force, in an introductory note to the prospectus, which he acknowledges was not written by himself, is made to say that "he has engaged the editorial assistance of those who were formerly its editors, together with a number of its contributors." And the same thing is said in the body of the Prospectus in still stronger language, as follows:—"The new series of the Genesee Farmer will have the editorial powers of gentlemen already distinguished in this cause, and long engaged in the editorial department of the old series, and thus offer the best security in return for the patronage of the public."

The representation here distinctly made is that the spurious Genesee Farmer is to be conducted by the editors of the *present* Genesee Farmer. Indeed the pledge that it is to be under their control is given as "security" to the public that the paper will be worthy of their patronage. The public can judge of the value of this "security," when they are informed that the statement is entirely *destitute of truth*—and that no *person* connected in any way with the editorial department of the Farmer for the last six years, has been or can be engaged to aid the proposed dishonorable attempt to transfer to an irresponsible concern the reputation or patronage obtained by nine years indefatigable service in the cause of Agriculture by the present conductors of the Genesee Farmer. It is, however, proper to say that the "N. Goodsell," whose name figures in the Prospectus with that of J. E. Force, was employed as a writer for the weekly Farmer during the first years of its existence; but he *six years* ago, without a moment's notice, or a word of difficulty occuring between us, broke off his engagement, and started an opposition paper called "*Goodsell's* Genesee Farmer," which proved an entire failure, as he did not succeed in withdrawing from my paper either its reputation, correspondents, friends or patronage: and the *base attempt*, as it was considered by all familiar with the circumstances at the time, proved an utter abortion, the paper having never completed its first volume. The public will be able to judge from this statement of facts in relation to "N. Goodsell and J. E. Force," whether their Prospectus is worthy of credence, and whether they will be likely to receive a paper worthy of their patronage, *or even any paper at all for any great length of time,* for such payments as may be remitted in advance for the counterfeit Genesee Farmer.

The contemplated union of the Genesee Farmer and Cultivator, (occasioned by the lamented death of Judge Buel,) has, so far as has come to our knowledge, received the warm approbation of the friends of both papers. It may, however, not be amiss to caution the public against any *other attempt* which may be made to build up a spurious paper on the reputation and character of the Genesee Farmer, and thus defraud and disappoint the public, as we learn that there are other persons in this city who are prepared to make the attempt in case of the failure of the above named persons.

LUTHER TUCKER.

Postscript.

Since the above was written, I have learnt that Force has sent off to the West large numbers of these Prospectuses *with the November No. of the monthly Genesee Farmer*, the mailing of which he has delayed probably for that very purpose. Postmasters and others should therefore be on their guard against the Prospectus of Force and Goodsell, as it is not unlikely that they may find some of them done up in my papers. It may be proper also to state, that Force now assures me that he *shall not issue the proposed paper*, which I presume will prove true, as he must have relied upon anticipated *advance payments* for the means necessary to go on with it.

Second Postscript.

Force, who mailed a part of the November Monthly Farmer, was directed to put into each parcel a Prospectus for the Cultivator, but we have great reason to fear, from the following letter, that instead of sending our Prospectus, he sent his own, with such of the Farmers as he mailed:

"*Milan, O. Nov.* 26, 1839.

"Mr. Tucker—In your last No. of the Farmer you state that you will forward with each package a Prospectus of the united paper of Farmer and Cultivator.—As yet I have received none, but have received one of the Genesee Farmer to be conducted by Messrs. Force & Co. Now this work is new entirely to me, and I know nothing about its proprietors, and cannot speak in favor of it. I wish therefore you would, on the receipt of this, send me immediately two prospectuses for the united paper, so that I can solicit subscribers for it, and oblige yours, &c."

[*From the Farmers' Register.*]

On Fattening Hogs, by cold-soaked and fermented food.

You complain very justly, I think, that many of your first contributors have grown weary in well doing; in other words, that their communications have greatly fallen off in point of numbers. Although I myself am unconscious of being one of the culprits, I determined immediately upon reading your remarks, to act as if I really was one, and felt anxious to evince my repentance by forthwith inditing to you an epistle of some kind or other; but could think of nothing, at first, that appeared worth communicating; luckily, however, in the midst of this quandary, I picked up at second hand, from a friend, something in regard to the mode of fattening hogs, which seems to be well worthy of notice.

First, however, I must tell you, that having, for a year or two past, enrolled myself in the fraternity of root-steamers for stock, (horses and sheep excepted,) my own experience is not yet sufficient to report to you any result of trials made by myself. I must farther confess that, as a novice in the steaming business, I still retain somewhat of that incredulity which I always feel relative to the benefits of any practice, when they appear to me so exaggerated as those do that are generally ascribed to the steaming process. But being open to conviction, and utterly condemning the old and common wasteful method of fattening our hogs, I was much gratified to hear the account which I will now give you of the mode practised by some gentleman, whose name I forget, in King & Queen or King William.

One or more casks or tubs are nearly filled with alternative layers of chopped cabbages or roots, and broken ears of corn. Enough boiling water is then poured into the vessels, to cover the food. This is suffered to stand about twenty-four hours before it is given to the hogs, by which time some fermentation takes place, if the fattening process is commenced as early in the season as he commences it, which I understand he does long before frost. A constant supply of this food is given until a very short time previous to the hogs being killed, during which they have corn alone, which is generally deemed necessary to harden their fat.

By this method we may save the expense of steaming apparatus of every kind, such as have been heretofore recommended in our agricultural papers. It is true that some of these cost very little compared to the advantages derived from them; but this little, even in the cheapest that I have seen mentioned, is worth saving, if it can be done by some contrivance still cheaper, and preferable on other accounts, as the one which I have just described, appears to be.

I am gratified that I have it in my power to give you the foregoing information at this particular time; for I have long been convinced that we should probably save at least half the expense of fattening our pork, if we would commence doing it by the first of September, or even sooner, and give much less corn than we generally do. To postpone putting up our hogs for the sake of the acorns and chinkapins that they may be able to find by incessant travelling about in search of them, is as complete an illustration as I have ever known of the old proverb,—"*penny wise and pound foolish:*" since to say nothing of the notorious fact, that *hogs especially*, fatten much faster in warm weather than in cold, and when they can fill their bellies without having to travel miles for the wherewithal, (being the laziest animals upon earth, except the gluttonous man, and his prototype, the quadruped called the sloth,) more of them are lost by theft, if suffered to run at large, during the nut and acorn season, than would pay, twice over, the whole expense of feeding them in pens with food that cost us little or nothing, except the labor of collecting and preparing it. Even that portion of this stock which we call "*out hogs*" could probably be kept much more economically, if not suffered to run almost wild for half the year; and were supplied with food by their owners, instead of being left to supply themselves. As they are commonly managed, we may truly estimate the annual loss, in most cases, at nearly or quite half of the whole number; for many are killed for trespassing on our crops—starvation during three-fourths of the year, having taught them to be thieves; whilst a still greater number are stolen in the fall, after they get a little flesh on their bones, for a reason which I once heard alleged by an old negro in extenuation of the practice of stealing them, that "hog meat was so miserable sweet his fellow *sarvants* could not help stealing it."

Hoping that you will deem this new process for fattening hogs worth publishing, I remain, dear sir,

Yours very sincerely,
JAMES M. GARNETT.

August 31st, 1839.

Chinch Bug.

To the Editor of the American Farmer:

In the last Farmers' Register there is an extract from the Genesee Farmer, in which the "Chinch Bug is described as peculiarly a southern pest originating in the woods, from which it spreads in every direction, attacking indiscriminately wheat, corn, and indeed the most of the cultivated grains and grasses."

The writer of this communication is correct in some of his position; in others he is not.

The Chinch Bug has invariably first made its appearance in the wheat crops in this section of the country, and in all others that I have heard from. From this fact some of the most intelligent farmers in this section of the state have come to the conclusion that the Chinch Bug originates from the Hessian Fly, as you always discover them in our wheat fields near the ground where the Hessian Fly first makes a deposite of its egg.

The farmers, some thirty years since, in Orange county, in this state, had to abandon the seeding of wheat for two years, which I consider a conclusive fact, that the Chinch Bug must originate from the Hessian Fly, as all those who are acquainted with the history of the former, must know that the mere abandoning of the seeding of wheat would not have prevented the reappearance of the bug unless they originated from the fly. The bug was never known to make its appearance in any other than the wheat crop; it was never seen in this section of country until the Hessian Fly made its appearance in our wheat fields, which is another fact showing conclusively that they must originate from that insect. The rye crop is the only grain which is exempt from its ravages, at least my experience bears me out in the assertion. I seeded a field in oats, wheat and rye, the last season, the oats and wheat were injured by the bug, but they did not molest the rye; they would march around it, but would not molest it.

The same writer says, "though provided with wings, they seldom used them, and their disappearance is as sudden as their appearance."

This is not the fact in their history in this part of the country. Some here have asserted that they would take flight from our fields in July and August, and a new crop of them would come in September; but this has not been their history this season—they make their appearance in our wheat field the last of May, and the first of June, and continue therein and in our oat fields, until the grain is cut and secured, and they then march with all their forces and commence their attack on our cornfields, where they continue until the cold weather commences, and then take flight to the woods, though you may discover them in our corn-fields sheltered in the boot of the stalk in the depth of winter, yet they rarely survive the winter. I have discovered them in July taking flight from our wheat and oat fields, and you may see thousands and millions flying to the woods, from which I am under the impression they never return, but they leave a new generation behind, which are more destructive than their progenitors. No person can have the faintest idea or conception of the ratio of their increase unless they study their history and movements. At this time there are myriads in our corn-field attached to the stalk, and they shelter under the boot or shuck of the stalk, and there multiply beyond conception, hundreds perhaps thousand attached to a single stalk.

Some allege that the Chinch Bug takes shelter in stumps and broom sage, or old trees, during the winter, and commence their operations as soon as warm weather takes place in the spring. To prove beyond controversy that the Chinch Bug does not originate in this way in our wheat fields, I have known fields that had not a stump or any thing in them to protect them, and the wheat was very much injured by them; and in fact our tobacco land is most generally seeded in wheat, where there was no appearance of a Chinch Bug; you might discover them as abundant and as destructive in lands of that description as you would in any other field. As far as my observation extends, (and I have been examining into their history for twelve months) this insect perishes during the winter months; this I know to be a fact, as I seeded a field in oats this last spring, which was in corn last year, and examined minutely thousands of corn-stalks which had stood in the field during the winter, and you might discover thousands that had perished. I had the corn-stalks carefully collected and burnt, and I did not see a Chinch Bug in the field. You might discover the chinch in tobacco fields, entirely remote from any other field, and surrounded by woods, which was seeded in wheat, and I am told that the Chinch Bug was very destructive.

The only alternative left for farmers and planters of this state, and all other districts of country, to rid themselves of this truly alarming and formidable enemy, is to abandon the seeding of wheat for two or three seasons, as I am confident it is the only plan by which we can subdue this insect. It is awful to reflect upon the consequences that must ensue to this portion of the union, if the ravages of this insect are not stayed. Notwithstanding the most propitious season which the farming community have enjoyed for 20 years, we find since the fodder has been gathered and the tops cut, the corn crop has been seriously injured.

Whether the position which I have taken is correct, that the Chinch Bug has its origin with the Hessian Fly, remains for time to develope. This is the conclusion which some of the most intelligent part of the community have come to. I cannot in all my researches and examinations and inquiries, find any other cause by which this insect can come into existence.

JAS. W. JEFFREYS.

Red House, N. C.

The Chinch Bug and Hessian Fly.

Red House, N. C. Oct. 16th, 1839.

Mr. Editor—A writer under the signature of Agricultor has replied to a communication of mine published in the American Farmer relative to the Chinch Bug.

"Agricultor" wishes to know my meaning of the word "progenitor," as used in my communication. My meaning was this: after the Chinch Bug comes into existence, it produces a new race, which in a short time arrives at sufficient maturity to take wing and fly in swarms to the woods; and that those left behind are more destructive in their depredations than those who thus take wing. Their habits are very much like bees; they are very industrious, and are incessantly sending out a new race, or new swarms; those that are left are more destructive on account of their incapacity to escape. All those who have studied their movements and habits, and watched the various stages through which they pass, would confirm the position I have taken.

Agricultor says: "and if so, they say it presents a very anomalous case in the natural history of animals, to wit, that of two very unlike *parentages* producing *similar offspring*."

In reply to this part of his communication I will introduce a new race of the insect tribe to prove that the insect does undergo various changes, and that unlike parents do produce similar offspring. Agricultor may think it strange and contrary to the order of nature that those large white grub worms could be transformed or turned to grasshoppers. But such is the fact. A gentleman of highly respectable standing in this country, (no doubt he was philosophizing like some of the Agricultor's neighbors) who caught one of those long white cut worms and placed it in a box with some loose earth, and after it was confined for some days, he examined it one morning, and found it had changed or produced a grasshopper. Is it more strange for a cut worm to be transformed to a grasshopper, than that a Hessian Fly should deposite an egg which should produce a Chinch Bug? Grasshoppers produce grasshoppers, and Chinch Bugs produce Chinch Bugs.

Another case—How does Agricultor account for the Tobacco Fly depositing an egg on our tobacco, and after some hours by the heat of the sun, the egg produces a cut worm nearly as destructive in its operations as the Chinch Bug. This last case is well known to every planter of the south who cultivates tobacco.

Is it more strange that the Hessian Fly should deposite an egg in the boot of the wheat and be brought into existence by the heat of the sun, than that a Tobacco Fly should deposite its egg on a tobacco leaf, and that egg should be transformed by the same cause to a cut worm? I could adduce other cases in the insect tribe to convince Agricultor and his sceptic neighbors of *unlike parentages* producing similar offspring.

I will now reply to the first part of his communication.

Agricultor has called it a "novel discovery, and if verified by subsequent investigators of the mysteries of nature, the approach of a new era in the natural sciences, as far, at least, as the animal creation and procreation may be involved."

I can assure Agricultor that the idea of the Chinch Bug being a descendant of the Hessian Fly is not novel, as it can be traced as far back as the year 1783. About this period the battle of Guilford, N. C. occurred. There is a gentleman now living in Orange co. N. C. who is venerable on account of his age and great worth, who well recollects that when the British army moved through that county, there was a part of the army which were called the Hessian soldiers. Immediately after this event, perhaps that year, the Hessian Fly or Hessian Bug destroyed their crops of wheat. They believed and do believe to this day, that those soldiers left the flies or bugs as they passed through the country. The Chinch Bugs continued to destroy their crops of wheat for several years, until they were compelled to abandon the seeding of wheat. This aged gentlmen says they finally disappeared after four or five years.

After a period of 56 years the Chinch Bug has appeared in the same district of country, and upon the same tracts of land.

I have no douht that I could procure the testimony of fifty men of unimpeachable character, who believe that the Chinch Bug is the true descendant of the Hessian Fly. Agricultor may call it *old fashioned* stuff, but let him lay aside his books upon such subjects, and go and examine the operations of nature in these matters, and he will see great and strange transformations, proving that *unlike parentages* can produce *similar offspring.*—I am a plain homespun man, and draw my conclusions from the operations of nature. I should have been thankful, and no doubt this portion of the country would have felt themselves much indebted to Agricultor. to have given a better history of this insect, and given us his views relative to the best mode of preventing their depredations. We do not care for their genealogy—we wish to destroy them and not perpetuate their names.

JAS. W. JEFFREYS.

Of the Fallow.

(Concluded.)

After the land has been ploughed a second time, the question arises, whether the surface should be left in a rough furrow state or harrowed fine down? To this the reply is by no means difficult, since the rougher it is left, the greater is the surface exposed to the sun, rain, and wind, and, as the object is to have the surface as dry as possible before being again ploughed, the roughest state is then to be unquestionably preferred.

When the land is once dry, to have it any longer exposed, unless waiting for a shower, is useless, since the clods and crumbs can be no more than dry if they remain exposed for weeks in an arid season, for their affinities are at rest, as in paper or dry wood, decay or decomposition is prevented, and therefore no after enrichment is to be expected. If a good shower should come, it will prove of great value by falling on a dry surface, by causing a circulation, first of fresh water through the clods, and then succeeded by fresh air, as the former dessicates beyond what is chemically and mechanically retained by the soil; but when again dry, no time should be lost in turning this surface under with the plough, and bringing up a fresh one to be similarly exposed; because more advantage will be gained now, by exhibiting a fresh surface to the sun, &c. than permitting it to remain unmoved.

It is quite necessary for land to lie undisturbed after ploughing, for a certain time, before another takes place; as is the case when making bread, hay, beer and wine,* otherwise a fallow might be completed in a day, which is impossible. Now the usual period that intervenes between fallow ploughings during the spring and summer months, is from two to five weeks, which experience and the economy of a farm have decided to be sufficient and practicable; the appropriate rollings, &c. being of course applied when necessary, particularly if recently manured,† as the superficial dressings will assist in the general fermentation, therefore, in the decomposition and combination of the vegetable materials with the particles of the soil.

Before the third ploughing is entered upon, a heavy roll or a light one, according to circumstances, should be passed over the field across the furrows, and this implement alone will effect, generally speaking, all the requisite pulverization at the least expense of culture & treading. This act of pulverizing displaces the previous position of the particles of the soil, and brings others into contact, thus highly favoring fermentation. If the roll be unable to accomplish the present intention, the harrows or the scarifier, or both, may of course be employed.

Suppose the third ploughing to be completed, the soil will now present to the eye and touch a great improvement in its color, its state of pulverization, and in its inexhaustible moisture beneath. If turnips are to succeed the fallow, and the fourth or fifth ploughing is to be the last, then, before this takes place, the surface of the field should be reduced to the finest tilth by the harrows and roll, when the land and weather are favorable, that the seed, when sown on the subsequent plough furrow, may be deposited in and surrounded by an entire mass of close yet permeable soil, from being finely pulverized, of from six to ten or more inches in depth.—This is the very object of the husbandman, because, a body of earth in the above condition is the one, experience has ever found, most congenial to the infant germination and future growth of the turnip, and which, according to seasons, will attain in consequence the limit of its development and produce.

The benefit of the fallow process may be summed up in these words: that it replenishes the soil with fresh air and fresh water, improves its powers of composition and decomposition, strengthens its affinities for the products of vegetable and animal substances, renders it easily permeable to the roots of plants, and restores, by the general pulverization, its valuable property, inherent in rich soils, the absorbing and retaining of moisture and air from the atmosphere.—*Bland's Principles of Agriculture.*

Important Facts.

We observe with astonishment and regret, the conclusive evidence which appears in every direction, that the business of agriculture does not receive the attention due to it in this country, but it is treated with absolute neglect, compared with other pursuits. This ought not to be, and the inhabitants of this country will yet learn, that they have committed a gross error by abandoning the cultivation of the soil, for less independent and more precarious modes of obtaining a livelihood.

Who has ever heard of such a state of things as now exists here? We have a soil as fertile as any that the sun ever shone upon, a country almost boundless in extent, and so cheap, that any man may purchase a farm with the proceeds of a few months labor, yet we are actually importing for consumption, immense quantities of agricultural products from foreign countries! A people, thinly scattered over a land unequalled in fertility, and exhaustless in its resources, are buying their bread, at enormous prices, from countries so overburthened with inhabitants, that political economists have feared that the earth would fail to produce sufficient to support them. Such an extraordinary and unnatural circumstance should excite attention, and awaken the inquiry as to its cause.

The fault, as we have seen, is not in the soil, nor is the country overrun with inhabitants. It is, therefore, evident that the cultivation of the soil is neglected, otherwise we should be exporting agricultural products, but it is easier to show the fact, that agriculture is neglected, than to find a sufficient reason for this neglect. We apprehend, however, that it will be found to spring in a great measure, from the same causes which have produced much evil in this country, and the bitter fruits of which we are now reaping. The first and chief of these causes, is the inordinate thirst for wealth, which pervades every class of society, and induces men to abandon their legitimate business to engage in some wild, hazardous speculation, in the hope of becoming suddenly rich. It is also too often the case that the farmer becomes tired of the moderate and gradual accumulation of property by the products of his land, and leaves the cultivation of it to engage in the business of commerce or manufactures. He finds out his egregious mistake when it is too late. The property he had accumulated is often squandered and lost in consequence of his ignorance of his new business, and he again sighs for the cheerful and independent mode of life which he has abandoned, when it is out of his power to resume it. We have in our mind numberless instances of this kind, where industrious and prosperous farmers have been lured to their ruin, by being induced to lay aside the implements of husbandry, and engage in the universal scramble after sudden wealth.

There is another great error prevalent upon this subject, and that is, the business of agriculture is generally looked upon as less respectable than that of commerce, manufactures, or the professions; and wealthy farmers, instead of teaching their sons their own business, most usually transform them into merchants, lawyers, doctors, or dominies. This is all wrong. Agriculture is the very back-bone of all business, the main-spring of all wealth, and should be regarded as a profession of the highest respectability. It gives those engaged in it a feeling of independence, genuine nobleness without ostentation, honor, honesty and firmness, well calculated to perpetuate the free institutions of our happy country. The truth of the eloquent panegyrics of the ancients upon this employment may be more easily realized here, than in any other country upon earth. We confidently hope to see public opinion speedily righting itself upon this subject, and to find people seeking their permanent interests, and advancing the prosperity and glory of our wide domain, by engaging more generally in this healthful, honest and independent business.—*N. Y. Sun.*

---

* Likewise with a fire, which requires, when endeavoring to get it up strong, to remain a time after every stirring, to allow of the requisite changes and combinations taking effect.

† Land should remain the longest after that ploughing which turned in the manure of a vegetable nature, but then should be well dressed with the scarifier, harrows and roll, and the dressing repeated, then ploughed up again, to air the soil, for the foul matter to escape, and to imbibe fresh. This exposure might continue for a week or two, of course depending on the weather, then the manure ploughed under again, to remain some time, and to receive the proper dressings. If any seed or corn is to be sown, let it be generally on that ploughing which turns the manure in well beneath.

[*From the Sangamo Journal.*]

Important to Farmers.

There are few of our farmers who have not witnessed the effects among cattle, of a disease known as the *mad itch.* It has sometimes carried off the most valuable stock; and all efforts to arrest the disease appeared to be useless. We think we can now lay before our stock raisers a remedy for this disease. It was discovered by Mr. David Simms, a farmer, living on Lake Fork. Considering it valuable to the public, he has handed us the annexed notice of it for publication. We would suggest to our farmers to preserve it, as it may prove of more value to them than the amount they would be required to pay for a dozen volumes of the Journal:

To the Editor of the Sangamo Journal—

The undersigned takes this method to inform the farmers and all those who raise cattle, that he has discovered a cure for the mad itch, a disease which is often fatally destructive to that species of stock. Last winter was two years, when I had four cows attacked with the above complaint, and I tried every thing I could think or hear of, to cure them, but with no good effect. This winter another of my cows took the same disease, which I discovered early one morning; and as soon as I discovered it, I gave her as much soot and salt as she would lick, and in a few hours after, I gave her from three quarters of a pound to a pound of pulverized brimstone. In the morning following, I gave her as much salts. The cow is now well, and is as hearty as any of my cattle. It is my opinion that sulpher itself will cure, or sulphur and salts given in the way prescribed. The cure was effected in about a week. The remedy operates severely for two or three days as a purge.

To those who are not acquainted with this disorder, I will inform them that it first comes on with a kind of hiccoughs or jerks at every breath. The brute jerks itself full of wind; frequently licking their sides and back; occasionally rubbing their heads; and if not stopped in five or six hours, they rub with apparent madness, and continue to swell until death takes place, which will be within about ten or twelve hours after the attack.

This cure is from experience, and I give it for the good of my fellow-citizens.

DAVID SIMMS.

Logan Co. March 15*th*, 1839.

Management of Sandy Loams, &c.

Mr. Ducket, of Surry, England, a most accomplished and successful farmer, ascribed the luxuriance of his crops to three principles, which he laid down for his guidance, and strictly adhered to. He relied, upon, 1st, deep ploughing, by means of which the roots of his plants were permitted to penetrate the earth to a depth where they found a uniform moisture, by which they were preserved in a healthful and flourishing condition, while those of his neighbors, who were *shallow* ploughers, in seasons of drought, were measurably destroyed.

In Flanders, in the Peys de Waes, where the soil was originally a barren white sand, by a sure process has been brought to a state of fertility which entitles it to be called a fruitful loam. At first it was barely scratched, being ploughed not more than ten inches deep; it was subsequently gradually deepened as it was enriched,—and it is now stated that this barren sand has been so fertilized that it bears to be entrenched to the depth of fifteen or eighteen inches. This operation is performed every seven years.

Clay soils.—All clay soils intended for spring culture should be turned up in the fall, to receive the benefit of the action of the winter's frost, which mellows and reduces it infinitely better than any treatment which man is susceptible of giving it. If very tenacious, its condition may be greatly improved by simply adding sand to it, after the ploughing, and so harrowing it as thoroughly to mix the two together. Instances of the success of this practice are numerous in Europe, and are said to have been so decidedly striking as to excite surprise. In numerous cases the advantages have been equally as great as if the clay has been heavily manured.

Milch Cows.—These animals should always, if possible, be kept where they can have free access to good water, whether ranging in the pasture or confined in the barn-yard. From experience, we hesitate not to say that having water always at hand will make a difference of 25 per cent in favor of their yield. In winter no man should pretend to keep a cow to the pail who does not provide her twice a day with either good rich slops, pumpkins or roots. How in the name of St. George can it be expected that a cow fed upon dry hay, fodder or tops, from November till April, can secrete any considerable quantity of milk; we know that there is a large quantity of nutritive matter in each of these kinds of provender; but to replenish the udder, it is necessary that some such liquids or succulent pabulum named, be daily given. No one should keep a cow to the pail who does not keep her well; humanity as well as true economy are both consulted in so doing.

Marl.—The meliorating effect of marl has been known in Europe for a long time, and clay, stone and shell marl have been severally used with decided advantage, and as our tide water regions are well supplied with each of those varieties of calcareous matter, we trust, as a beginning has been made, that wherever obtainable, our farmers will freely use it. Of this they may be certain, that nothing like permanent improvement can be effected without the use of calcareous manure of some kind. With the aid of lime, or marl in some one of its forms, with the addition of grass leys or green crops of some kind turned in, almost any soil may be pushed beyond even its primitive state of fertility.

Accumulation of Manure.—The scrapings of the road, the lanes, leaves collected from the woods, weeds from fence corners and any where else, marsh mud, fresh or salt, and indeed all vegetable or animal offal, if spread on the surface of your cow yard, becomes in a few months as good manure as stable or cow dung, for in addition to their own specific virtues, they sponge up and retain great portions of rich liquids which would otherwise be lost. All cow yards should be basin-like in form so as to prevent the escape of such liquids.—*Farmer and Gardener.*

Advantage of Manure.

We have frequently endeavored to call the attention of our readers to the subject of manures, and of applying them to the soil, but we fear that farmers in general, do not sufficiently appreciate their value. Our reason for forming this conclusion is, the prevailing inattention to the matter; although farmers are ever ready to acknowledge their conviction of the value of manure, yet we think their negligence in applying the means for procuring, preserving, and applying it to their lands, is a plain proof that its real value is not generally known.

The following short narrative is as plain a demonstration of its profitable effects as we have usually found; which, although we were not eye witness of the facts, came to us through a channel which left no doubt of their correctness.

A gentleman, somewhat inexperienced in the business of farming, sowed a piece of ground containing about twenty-one acres with wheat, at the rate of one bushel per acre, from which he obtained only twenty-one bushels, or about the quantity sown. Thinking that the result might have been owing to some unfavorable circumstance, to which a second crop might not be subjected, he again sowed the same piece of ground with a like quantity of seed, and again obtained a crop similar to the first. This latter result induced him to think that the failure in both cases, was perhaps occasioned by the exhausted state of his land; he therefore resolved to test the effect of manure, and accordingly collected what he could, and applied it to one acre of the same ground, which acre he sowed a third time, and obtained from it twenty-one bushels, or as much as the whole twenty-one acres had produced without manure.

We not unfrequently receive details of as profitable results from the application of manure as the above, and we have not a remaining doubt, but almost all exhausted land might, with proper culture, be as much or more improved; but what adds consideration to this, is the great improvement in so short a time. And it goes further to prove the utility of applying manure liberally on a small piece of ground, rather than the too common practice of scattering a small portion over a whole farm of considerable extent. Had the gentleman in this case have scattered his manure over the whole twenty-one acres, it might have yielded him more grain than he obtained from the one acre, but we must observe that it would have required twenty-one bushels of seed instead of one, and besides, a great deal more labor and expense in cultivating, which items would have greatly reduced his clear profit. This error in the most of our farmers, produces a serious drawback, and cheats them out of the greater part of their profit; if, instead of one hundred acres, they would apply the same amount of labor and other expenses on twenty-five, they would raise as much or more produce and consequently their clear profits would be greatly increased.—*Farmer's Advocate.*

Saltpetre in Meat.

Lansingburgh, N. Y. August 5, 1839.

It is a matter of regret that while so much salt meat is made and used, we have not yet acquired the proper knowledge of the best mode to prepare and preserve it; nor is it known how noxious salt meat may become by an improper use of saltpetre in the pickle or brine usually employed.

There are various modes of preserving salt meat and fish, by drying, salting, pickling, oiling, smoking, &c.; but I merely mean at present to notice some of the defects and noxious properties of our actual meat, either beef or pork.

One of the main defects appears to consist in the useless addition of saltpetre to the pickle whereby the meat often becomes sour or spoiled, and always acid and pernicious. I never could understand why this substance was added to common salt, except that it is said to make it look better. But it ought to be known that saltpetre absorbed by the meat *is nitric acid or aqua fortis, a deadly poison!* whereby our salt meat becomes unpalatable and pernicious. A slight excess of this acid renders the meat sour, or spoils it, as we say. It has been suggested to correct this by potash, which re-absorbs this excess; but this only hides the defect without neutralizing the whole poison.

Is it not surprising that we should feed and deal, as a staple of our country, with an article containing a portion of such active poison as *nitric acid?* In fact, our salt meats are *no longer meat!* They are a new pernicious substance produced by a chemical action of salt upon the flesh of animals. This flesh, when fresh, consists chiefly of *gelatine and fibrine.* Gelatine or jelly is the substance soluble in warm water, forming a broth by boiling, or becoming a jelly by concentration; while fibrine is the fibrous tough part of the meat, which cannot be dissolved, and is therefore unfit for food, while gelatine is the nutritious part of the meat.

But it is well known that salt meat and even corned beef can no longer afford a broth, and therefore the gelatine must have been changed to another substance no longer soluble, nor so nutritious, by the chemical action of salt and saltpetre. To this new substitute chemists have not yet given a name; but it is as different from meat as leather is from the hide before it is tanned by the tanbark or *tannin.*

To this chemical change in meat are to be ascribed all noxious qualities of salt meat, and the diseases to which those who feed chiefly on it become liable; sea scurvy, land scurvy, sore gums, rotten teeth, biles, ulcers, &c. which we entail on ourselves by using a kind of poisoned bad meat, which we call salt.

This important and doleful fact ought to be well known generally to all those who raise cattle, cure meat, or consume it, in order that they may correct this sad defect.

The first thing to be done is to abandon altogether the use of saltpetre in curing meat. This is indespensable, and no one who is told that aqua fortis is the produce of it, ought any longer use this poison in pickles or brines.

The best substance for it is *sugar.* A small quantity makes the meat healthier, sweeter, nicer, and quite as durable. Let this be known to all our farmers and sailors.

How to make brine for meat perfectly innocuous, is yet a desideratum. Gelatine ought to be preserved in salt meat pure and soluble, as it is broth in cakes, before any salt meat can be perfectly healthy and equal to fresh meat. But at any rate by withholding the saltpetre, we divest it of a deadly poisonous substance.

C. S. RAFINESQUE,

Prof. History and Natural Science, Elm Place.

Agricultural Warehouses.

One of the great causes which has led to the superiority of English agriculture, is to be found in the establishment of agricultural warehouses, nurseries, seed-stores, &c. in all the principle cities and villages of the kingdom, where agricultural implements of the best kinds, seeds and trees of the best quality and varieties can be obtained by all who wish them, at reasonable rates. The establishments of Loudon, and of Knight, in London, and of Lawson, and Dickens, in Edinburgh, are celebrated for the extent of their collections, the great amount of business they perform, and the acknowledged benefits they have conferred on the agricultural world. In these warehouses, seed stores and nurseries, may be found ploughs, harrows, rollers, and all the tools and implements required by the farmer and gardener; seeds of the purest and most approved varieties, and fruit and forest trees suitable for every situation. A large proportion of the farmers purchase at these stores their seed wheat, their grass seeds, &c. and by long experience, the proprietors of these establishments, knowing the kind and quality of the soil, can better apportion the kinds and quality of seed required for such lands than the cultivators themselves. So extensive and necessary has these branches of business become, that in a late number of the London Gardener's Gazette, a list of those the most distinguished are given from the principal cities and towns, amounting to no less than 800.

In the U. States, such establishments could scarcely be less useful than they have proved abroad; yet their number is very limited, compared with what we think the advancement of agriculture, and the benefit of the farmer demand. A few, however, exist, and we hope their success will be such as to cause the establishment of others at all the principal points of our country. If in every principal city or village the farmer could be certain of finding at some store or warehouse, the implements he needs, of the best kinds and quality, he would esteem it a favor, as saving him much trouble in collecting from various places the articles he wants.—And so with places for the sale of seeds and trees, which are becoming daily more useful and indispensable.

The agricultural warehouse of Mr. Breck, at Boston, the publisher of the New England Farmer, is one of the most extensive in New England, if not in the United States, and has been found of essential service to the farmers of that region. In the city of New-York, a beginning was made some years since by Mr. Fleet, then publisher of the New-York Farmer, in establishing such a warehouse, and is now carried on with spirit, and we trust success, by J. W. Weaver &c. Co. 79 Barclay-street. With the warehouse is connected a seed establishment, conducted on liberal and honorable principles, and deserving the notice and patronage of the public. At Albany, Mr. W. Thorburn, (not of Chinese tree corn memory) has added the disposal of agricultural implements to his former business as a seedsman, and is doing much to bring within the reach of farmers in that vicinity, the best implements required by the cultivator of the soil. Several minor establishments have also been opened in the state, the business of which is rapidly increasing, and the benefits of which are every year more clearly felt and acknowledged. Among the seed stores of the state, the Rochester one holds a distinguished place for extent and usefulness, and the new arrangements of Mr. Bateham will doubtless give it greater efficiency and activity, and consequently diffuse its benefits more extensively through the district.

We always hail the establishment of nurseries of fruit or forest trees, warehouses for the sale of agricultural implements, and seed stores for the dissemination of seeds of good quality, and many varieties, as an omen of good to the country; as a proof that the spirit of inquiry and observation is awake, and that our farmers are beginning to appreciate the difference that exist between implements of the same name, and seeds of the same variety. Good tools, and good seeds, are indispensable to good farming, and this should be understood and practised upon by the farmer. A choice of seed will not unfrequently make a difference of one-third, or even more, in a crop of wheat or corn, and in nothing do farmers err more frequently than in sowing an impure, heterogenous mass called grass seeds, but in reality made up of all manner of foul stuff for grass seed, thus propagating and perpetuating various nuisances on their farms. We say, let warehouses and seed stores be well patronized so long as they furnish good tools and pure seeds. The country reaps the benefit.—*Genesee Farmer.*

Care of Farming Tools.

We believe it may safely be asserted, that the farmer in a course of years sustains as much loss, or is put to as much expense in procuring tools, by their decay in consequence of needless exposure, as from their actual wear on the farm. How many are the instances in which the farming implements, the ploughs, harrows, roller, &c. instead of being carefully housed when their use for the year is over, are left in the fields, or peradventure drawn up in battle array in front of the house, occupying a goodly portion of the road, and when covered with snow, forming most convenient places for breaking horses legs, tearing off shoes, &c. &c. Perhaps, in addition to these, are sundry wagons, carts, hay-racks, and other necessary things, like the former, exposed to the decay which must result from exposure to the rains, the freezings, thaws and snows of winter. Now, one such season of exposure does more to weaken the wood of these implements, promote decay, and render new purchases needful, than their ordinary wear on the farm, with careful usage and protection from the weather. As a general rule, it may be remarked that no implement, tool or carriage of any kind should be exposed when not in use. Those not wanted in the winter should be secured from the weather during that time; and so with those not required during the summer season, as sleighs, sleds, &c. The skillful, thrifty farmer is known by his attention to the minor points of agriculture, by his care to save, as well as to acquire; and he who neglects the lesser things cannot fail to find the drawback on his profits large and constant.—*Ib.*

Women Milking.

Thirty years ago it would have been almost as difficult to find a man milking as to find a woman mowing, excepting in cases of very large dairies. In this respect matters are greatly changed; and any hope, for aught we see, of getting back to the old practice, would be vain. Half of the young girls now-a-days hardly know, at least they would pretend that it would be immodest and not at all lady-like to be presumed to know, whether the milk comes from the udder or the horns. "The rosy milk-maid," the title of a song which we remember to have often heard when a boy, is an animal not known in modern natural history; and as to a young lady with thick shoes, a checquered apron, her sleeves turned up, and a handkerchief tied over her head, though the apron should be clean and the handkerchief as white as snow, and never so pretty a pair of black eyes and ruddy cheeks peeping out from under it, it would be an idea too shocking for one of your modern exquisites even to dream of; and if presented to her abruptly, while looking in the glass her *mousseline de laines,* with her satin shoes, her gilt hair-comb, her paste earrings and her insect waist, as crooked as the limb of a scrub-oak, she would probably not recover from the fright for a week.

We say we have no hope of recovering the good old habits of former days. Revolutions never go back.—Yet in this respect we have lost a great deal. Men are seldom neat enough in their habits to be trusted with milking. They have not the patience to wash their hands or to wash the udder before milking. They are not gentle, and often abuse the animal by their kicks and thumps. They are in a hurry in the morning to get through a business which they dislike; and they come home tired at night; the cows are necessarily milked at an unseasonable hour, and the business is very often very badly performed. Women, on the other hand, are more patient, more gentle, more faithful, more neat, and we were about to say—they ought to do the milking. The morning air would be bracing to their muscles, (if the modern girls have any muscles, for there begins to be a reasonable doubt in this matter,) and the odor of the cow has been long known to be, and is often recommended by physicians as medical. But we will not say what we were disposed to say, because it would be useless. It is utterly vain to attempt a contest with fashion; for according to Franklin's proverb, "he that spits against the wind, spits in his own face." We must, however, be just; and in riding through Dedham last week at the close of the day, it was quite refreshing to see in at least four cow yards, woman in her appropriate sphere; and by her pleasant looks and her gentle conduct as she sat at the side of the bountiful cow, evincing her gratitude to Providence for this richest of all the benefactors which Heaven has given to man in the form of a quadruped.—*New-England Farmer.*

Bringing Cattle to the Barn.

The 20th of November is universally understood throughout New-England as the close of the season of pasturage, and the time for bringing our cattle and live stock to the barn. Sheep may be left out as long as the ground remains bare; but it is believed to be bad management to leave cattle out after severe frosts come; and especially in storms of sleet and snow. Fat cattle in the fatting districts are tied up to be fed and turned into the yards at night. In this case the yards are well littered and a dry place is always furnished for the cattle to rest upon. For young cattle, well protected yards and open sheds with a southern aspect, are to be preferred to close and warm barns. For milch cows, however, stables which are dry, warm, but well ventilated and well littered, and kept thoroughly clean, should be provided, and these animals should never be exposed to cold rains or storms, or winds, which make them shiver and become restless; and of course cannot fail to diminish their milk. They should be well fed, and carefully curried, and treated always with gentleness and unvarying kindness. It is impossible to reconcile the careless, slovenly, neglectful, and we may add, inhuman manner with which these useful and beneficent animals are commonly treated, with any just regard to the farmer's own interest or even with the principles of common justice.—*New-England Farmer.*

Foreign Agricultural Extracts.

[*From the London Farmer's Magazine.*]

On Farm Manure.

To the Editor of the Farmer's Magazine.

SIR—It cannot be expected, while men differ upon every subject in religion, morals, and politics that there should be a perfect uniformity of judgment in the leading divisions of agriculture. The constitution of our moral powers leads to differences of opinion—this difference arises from education, prejudice, habit, and indolence; the dropping of water, however, at last wears a stone; and seeing how many impediments stand in the way of improvement, we must not be discouraged by the slow advances which have, as yet, been made in agriculture. It must be admitted also that many farmers are so limited in their capital as to be, in a great degree, unable to try costly experiments or to undertake considerable improvement; but *all* of them are interested in the collection and distribution of their MANURE, and *all* of them have the means of attending to these important duties.

We have abundant proof of the vast benefits which a persevering desire of improvement has already bestowed; look at the various breeds of sheep! examine our celebrated specimens of stock! inspect the beautiful prize animal presented as the frontispiece to your last number! behold also the rich verdure and abundant crops which cover the valleys and mountains, fructified and improved by various modes of management and by various systems of cropping! Many deserts have been made to blossom and smile; many fields are now waving with golden-eared wheat which, but few years back, were worthless sheep-walks. It would confer a great obligation on the writer if some one of your correspondents would tell us the number of the millions of soughing tiles, buried under the surface of our lands, in order to drain and improve them. Nor ought we to overlook the various modes of artificial management now directed to general improvement by bones, rape-dust, salt, gypsum, &c. The agency of chemistry has, moreover, been solicited, and *she* is now giving to us the aid of her secret labratory. Within the memory of man scarcely a single acre of wheat was grown in Scotland; "oats full of thistles was the standard crop." Nor can any contrast be more striking than the well cultivated fields, at present heheld in our country, as compared with the cold, wet, and barren sterility which pervaded it formerly. Now the great agent in preparing this abundance is MANURE. It is therefore, well worthy of the farmer's inquiry, how far the influence of this great agent can be extended? How the quantity can be increased, and how that quantity may be rendered more effective as to production?

These remarks must be understood as applying to those lands which are under plough. It is hardly worth while to stop to inquire into the secrets of the causes of the exhaustion which land, in common with animal existence, sustains by continued exertion—it is a law of nature. I admit, however, that if the discovery of the cause could lead us either to *prevent* or to *retrieve* the diminution of strength, the inquiry might confer upon us a benefit; it is, moreover, an undoubted fact, that the rotation of crops *has* a tendency to lessen the inconvenience now referred to. There is some plausability in the doctrine of M. de Candolle, who maintains that the roots of plants eject certain excrementary matter which cannot be elaborated into the support and nourishment of the plant itself. This fact seems in conformity with the regular process of animal existence, in the elaboration of food necessary for support; and the wisdom of the Creator appears more than abundantly proved in the provision thus happily made for universal reproduction. It is, however, left to our own judgment and skill to make this law as beneficial as possible, and it is working along with an established law of nature, when we regulate and apply most efficiently the means of growth and fructification bestowed upon us by this excremental process, directed and distinguished by wisdom and goodness; it is, therefore, in analogy with an established system, when we conclude that the matter ejected from the roots of one crop may provide a stimulant for its successor. The mysterious cycle of decay and reproduction being in ceaseless movement through the whole range of creation.

In considering the subject of FARM MANURE, there are two matters which prominently belong to it, and to which I trust your readers will direct their attention.

First, as to quality.

Secondly, as to quantity.

The time is past and the doctrine also, in which it was maintained, that upon ordinary lands, a crop of wheat might be grown continuously without manure.—The process of fermentation and putrefaction is always at work in order to provide the food of plants, on which depends the support of all terrene animals, and as just noticed above, the wise provision made, for the beneficial action of decomposed matter in the work of reproduction, proclaims the wisdom of the process.

Let us, therefore, inquire, first, how the *quality* of manure may be improved and made most efficacious? The foundation of the farmer's management must primarily cousist of the straw consumed in his fold yard, and which in the first place supplies winter food for his stock—The more of this food therefore which undergoes the process of digestion, the better it is for his manure; the prominent duty of the farmer is, therefore, to keep *a quantity of stock in proportion to his quantity of food.* By this means he secures not only the profit upon his improving stock, but the profit also upon his improved manure; this mode conduces to the most profitable employment of the farmer's capital, and should, therefore, as far as practicable, be put into use; but *without* neglecting the subsidiary aid occasionally derived from the mere treading down of straw in the yard where it is exceedingly plentiful.

The next agent in the improvement under consideration will be found in the use of every *other* attainable variety of food in the farm-yard, such as turnips, oil-cake, beet-root, rape-dust, linseed, &c. &c. the better the food the better the manure heap; the more food taken to the fold yard to be consumed there, *in addition to the straw,* the more valuable will be the manure. It is now an ascertained fact that animals thrive much more rapidly when sheltered from the winter's blast. Mr. Handley, M. P. read a paper of Mr. Childers on the "Shed feeding of Sheep" at the late Oxford meeting, in which it was stated that an experiment had been made by the author which produced the following results. A score of hogs were fed equally upon turnips, linseed, &c. in a shed, with a score of the *same* weight which were fed on the *same* food in the field. From the 1st of January to the 1st of April, those which were fed at home, gained 19 stone 12 lbs. over those which were fed in the field, which is about a stone each per head. Those persons, however, who are in the habit of growing a pretty good quantity of Swede turnips, will always be in the possession of an exceedingly cheap, nutritious, and profitable food for the fold yard. No plant yields so abundant a supply either in the field or in the farm-yard as the Swede turnip.

The third regulation I recommend for the improving of the quality of manure, consists in the mixing of all the produce of the farm-yard together, the pig-stye, the stable, the dove-cote, and the feeding-shed must all contribute their respective quota of manure. The several products ought to be thoroughly mixed together, and if led out previously to the heap being applied to the crop, let such *other* supplies of night soil, rape-dust, ashes, &c. as are within the farmer's reach, be added thereto and mixed therewith, and then finally let a four inch coat of fresh soil be placed thereon as a covering to prevent evaporation till it is called into use.

The next matter to be attended to is the collecting in cisterns all the urine from the stables and feeding-sheds. About every ten days this should be pumped up and carefully dispersed all over the heap by means of a coarse watering pan. The ammonia (*hartshorn*) which is a constituent principle of urine, supplies a powerful stimulant in the process of vegetable growth, it ought to be carefully collected and dilligently applied, so as that it may percolate through the whole mass while accumulating in the yard.

Fifthly, the heap ought to be kept entirely free from any weeds whatever, the seeds thereof being almost indestructible. There ought to be channels, also, for the conveying away of all the rain water falling from the roofs of the surrounding buildings. The urine of the stock, together with the rain which falls upon the surface, will supply sufficient moisture; an additional supply will only tend to the impoverishment of the compost.

These several methods suggested for the improvement of FARM MANURE are recommended to the attention of your readers. So much space has already been consumed that we must leave that part of the subject relating to the *quantity* of manure for a future number. These suggestions are confined to those ordinary means which fall within the reach of the practical farmer, in order that they may be more generally useful.

When it is considered how much the productiveness of our farms depends upon the manure heap, and how much this matter is at times neglected, a few thoughts will not, I trust, be unacceptable which have for their object its improvement; and although familiar to most of your readers, if they should stimulate any person to apply them, who have hitherto neglected to do so, the object in writing them will be attained.

I am your obedient servant,
RICHARD HOPPER.
Papperwick, Nottinghamshire, Sept. 10.

Structure and Functions of Plants.

The cultivation of the various agricultural plants is by far the most important of the labors of the husbandman. The spontaneous productions of the earth are only suffient for satisfying the wants of man in a rude state of society: but as civilization advances, a taste for the comforts and luxuries of life is manifested in a greater degree, and the cultivation of the soil becomes important, in order to produce a greater quantity of vegetable food, and that, also, of a superior quality.

A knowledge of the structure and functions of plants is of the first importance, as laying the foundation of an economical system of culture. The necessity of becoming acquainted with the various phenomena of the vegetable economy is apparent; in order that the cultivator may avail himself of the great influence exercised, by human agency, over the productions of the vegetable kingdom, to the greatest extent. Apart from any considerations of profit, the study of the vegetative process affords greater pleasure than that of any other branch of natural science. But, if we can influence a seed so much, that, instead of growing up into a useless, stinted stalk, fit only for the herbarium of a botanist, it shall spring up luxuriantly, and send forth such a profusion of stems as to form a little sheaf of corn; or, expand its roots, which may be naturally hard and useless, into a large esculent mass, weighing many pounds; and, if we can do all this without knowing more than the means we have employed, might we not anticipate still greater and more wonderful effects, were we acquainted with the processes of the vegetable economy, by which such happy results were obtained? We should then be able to know what it is in our culture that has aided, and if there be any thing in it that has obstructed the processes of nature.

The importance of acquiring a certain knowledge of vegetable physiology cannot be pressed too much upon the attention of the cultivator. By means of selecting and improving the varieties of plants, the produce of our gardens and fields is not only increased in a ten-fold degree, but the *quality* of the produce is increased in a still greater proportion. The rose is the offspring of cultivation; the original plant, from which all our beautiful varieties have proceeded, is considered by botanists, to be the common wild brier. Our plums are cultivated descendants of the sloe; the delicious apples, whose species may be reckoned by hundreds, are the cultivated successors of the small, austere crabs; and our cauliflowers, cabbages, and other esculent vegetables, may be regarded as almost artificial products, so much has human skill had to do in their production.—Here the labor and assiduity of man are seen triumphing over the sterility of unassisted nature, and succeeding in bringing forth a race of beings calculated to supply his wants in a manner that the original species never could have done.

If the faculty of increasing the stores which Nature has already provided for his support, raises a man above the brute, that of adding new productions to those in existence, raises him above his fellow; and few subjects of contemplation can be more gratifying, or more elevating to a reflective mind, than this power as it were of creation, granted to his intelligence and industry.—Nor is it necessary to its enjoyment, that we should be either botanists or natural philosophers; or that we should devote more than occasional leisure hours to the pursuit. So boundless, indeed, is the scope which it affords for experiment, that it is in the power of any one, possessed of the smallest garden, and the least acquaintance with the principles of culture, so to improve the qualities of its products, as to add something to the common stock; while the farmer, who will take the pains to mark the progress of his crops, and to select from them the most productive ears of corn, and the finest roots and grasses for seed, may, by perseverance in such a plan, not only acquire wealth for himself, but confer an inestimable benefit on his country.—*Ib.*

The Rohan Potato.

Some time ago we directed the attention of our readers to a potato which the Prince of Rohan had introduced into culture in the neighborhood of Geneva, and which promised to yield very great returns. Since then it has received the attention of the agriculturists of Germany and France, who are not so much farmers as proprietors and scientific experimentalists, of whom there are many more of the latter class on the Continent than in this country, where scientific men will scarcely condescend to make experiments in the open fields. This potato has as yet attracted little or no attention in this country amongst farmers, and therefore we can give no account of any trials that may have been made of it here; but as it appears to yield large returns compared with many of the sorts in common cultivation, and though it seems a rather coarse potato for the table, it may prove useful in some districts for fattening live-stock. We shall communicate the latest intelligence in regard to the mode of its culture abroad on a small scale, no trials having yet been made in the open field.

The first experiments we shall relate are those of Viscount de Saint-Geniez, whose experience enables him to state that the Rohan potato is of a kind which has a strong tendency to grow above the ground, and, on that account, requires great earthing up all round about it, and, of course, it should only be set in ground deep enough to admit of earthing up.

"Towards the end of March of this year, 1837," says the Viscount, "I chose a large square bed in my kitchen-garden, equal to a good quarter of an arpent (1½ arpent = 1 acre,) which was made fine without dung. I formed lines of holes, east and west, at 3 feet apart every way, of 6 inches in depth. I divided the ground into three portions, north and south, and, of course, all having the same exposure. I then placed the sets of potato cut diamond-shaped, having each from one to three eyes, (dried for thirty-six hours on the side of the trench) into the holes, and covered them up with three inches of earth. Four weeks after, the stems began to appear, and, in a few days, they were above ground, which obliged me to fill up the holes. The stems growing tall, I tried this experiment with them: The first division was well earthed up all around, and a stout support placed at each mound of earth. The second was earthed up to the south, according to the advice of the Count de Turrenne, but had no supports. The third was cultivated as a kind of potato is cultivated at Roville, by that eminent agriculturist M. Dombasle, simply by letting the earth alone without earthing up and supports.

"I took up the potatoes on the 25th of November, and obtained these results: In the first division, with the plants earthed up all round, and with supports for the stems, which grew to the height of 6 feet, and the tubers weighing generally 4½ lb. 4 lb. 3 lb. and 2 lb. each, the crop weighed,…………………… 548 lb.

"In the second division, earthed up on the south and without supports, the tubers weighing 3 lb. 2 lb. and 1 lb. the crop was,…….. 364½ —

"In the third division without earthing up, and the ground left without any care but that of weeding, the potatoes being smaller than any of the above, the crop was,………… 318 —

Total produce,….. ……1,230½ lb.

"These 1230½ lb. raised on a quarter of an arpent, were produced from 30 lb. of sets, which gives an increase of 40-fold, which might have been raised to 60-fold if I had not made experiments contrary to the nature of this new kind of potato."

The Viscount comes to the conclusion, from the experience of the culture of the Rohan potato for two years, that earthing up largely is indispensable; that supports are necessary in a cold country, as a facility to the heat to penetrate to the tubers; but that supports are less necessary in a warm climate, as the creeping stems preserve the tubers from the great heat, and prevent, by their coolness, the mounds from cracking. It remains to be seen whether the same success will attend the culture of this potato in the open field, and earthed up with the plough, which the Viscount proposes to put to the proof.*

The next experiments which we shall relate, are those made by M. Pergot, at Rudt near Port-sur-Soane.—They are also on a small scale, but M. Pergot proposes to try the field-culture in the ensuing year.

"On the 20th April, 1837," says M. Pergot, "I planted, in holes 6 inches in depth and 2 feet asunder every way, 37 lb. of tubers, divided into sets having one or two eyes, and covered over with three inches of earth. The soil was sandy, and the space covered was 4.032 *ares* (an are being a square of 22 feet.) Three modes of culture were adopted; the first was just to fill the holes with earth the two others suitably earthed up. On the same day I planted, in the same manner, 187 lb. in a light soil of medium quality, covering a surface of 16.050 ares. They received the same culture as the preceding, but only there were no props to the stems which being 5 or 6 feet in length, covered the ground. They all flowered, what I had not seen since I began their culture three years ago. Yielding to the requests of several cultivators who adhere to erroneous practice, I planted 12 tubers entire, of the thickness of a turkey egg, and they have given me the worse produce, the largest not weighing 2 lb. The fear of frost determined me on taking up the crop on the 10th October, and I obtained

from the first field,………………………. 1,080 lb.
from the second,…………………………. 12,810 —

In all,……………… 13,890 lb.

or 62-fold. Most of the tubers weighed from 2 lb. to 5 lb. It is highly probable that they would have attained greater bulk, if I had not taken them up so soon, and if the stems had not been damaged by the hail which fell in the month of August."†

The peculiar result of these experiments seem to be, that the produce of 1080 lb. from 37 lb. of sets is only 29-fold, whereas the 12,810 lb. after 187 lb. of sets give 68½ fold the, average of the two being 48½ fold. The largest produce in these experiments was derived without support to the stems, whereas the results of Viscount de Saint-Geniez's experiments, given above, are quite the contrary.

The experiments of Vis. Morel-Vinde in some respects confirm those of M. Pergot, in reference to the largest produce being obtained without props to the stems, in the ratio of 58 bushels to 63 bushels per 2 1-6 perches of 22 feet square. Vis. Morel-Vinde, in the end of March, 1837, put into a good and light soil, not recently dunged, labored with the spade, containing 26 perches, divided into 12 equal parts of 2 1-6 perches, sets of two eyes at two feet apart each way; and each division was cultivated in a somewhat different manner, varying in the matter of props, and the number of hoeings and earthings up. The result from the whole was 666 bushels of potatoes from 26 perches of 22 feet square each; and, as the sets filled 20 bushels, the produce was 33 fold. A common kind of potato, yellow and round, and of less size, though more productive than others in its neighborhood, was planted at the same time with the Rohan; and its produce, in the best circumstances, was only 250 bushels from the 26 perches, or 12½-fold.

The remarks of Vis. Morel-Vinde on the nature of the Rohan, are valuable, and, in perusing them, the best method of cultivating it may also be learned.

"1. The Rohan potato," he says, "keeps together its tubers round the foot of its stem, and this property permits its being earthed up as much as desired.

"2. It produces its tubers so near the surface of the earth, that, without earthing up, many of them would show themselves above ground, assume a green color, and exhibit a great want of maturity. This property shows the absolute necessity of a large earthing up.

"3. This potato has need of moisture being preserved around the foot of the stem, the elevated position of the tubers exposing them the more to drought. It is this property which renders it indispensable to allow its large leaves to remain on the ground for the sake of the shade afforded by them.

"4. It carries flowers on almost all the stems, but it bears no apples, which may be explained from the circumstance of the large size of the tubers. The tendency of the sap constantly towards the tubers absorbs the elements necessary to the formation of apples, and deprives the plant of this mode of propagation.

"5. To form and ripen the large tubers, it requires to be a long time in the earth. It ought thus to be the first planted and the last taken up.

"6. I shall now speak of the quality of this potato, that varying according to the nature of the ground, and as often from different tastes; but at Celle Saint-Cloud I have subjected it to various cooking and culinary processes. I have had it tasted by great amateurs of the potato; and, if its quality is not superior to several fine and more succulent kinds, it is found at least to be of a good taste, sufficiently mealy, and superior to most of the kinds employed in feeding cattle or making starch."*
—*Edinburgh Quarterly Jour. of Agriculture.*

Fattening of Swine.

M. Bengtrapp mentions, in his work on the fattening of swine, several experiments which serve to shew the fattening powers of boiled carrots, potatoes, and some others. He brought up separately five couples of pigs, and obtained, after a certain length of time, the following results:

Couples.	Food.		Increase of Weight.	
1st got	55 decalitres†	of peas,………	22 st.	7 lb.
2d "	283 "	balls of wheat,	24	3
3d "	96 "	buckwheat,…	26	10
4th "	98 "	boiled potatoes,	20	4
5th "	175 "	boiled carrots,	28	2

These results of the experiment are unsatisfactory; because it is not mentioned whether the pigs were all of the same age and weight, nor is it stated whether the quantity of food marked in the table was as much as the pigs could consume. We have always believed that peas were the most nutritious food that could be given to pigs, and this experiment confirms the belief, as may be seen on comparing the relative increase of weight obtained from the various kinds of food: viz. 55 decalitres of peas gave an increase of 22 stones 7 lb. or nearly 6 lb. of increase of pork from 1 decalitre of peas; whereas. from boiled carrots, 28 stones 2 lb. of increase were only obtained from 175 decalitres, or about 2⅓ lb. from 1 decalitre, giving the advantage over the peas in the ratio of 2½: 1. The next most nourishing food is buckwheat, which nearly gives 4 lb. of pork from 1 decalitre. Boiled potatoes are next, giving nearly 3 lb. of pork from 1 decalitre. And the lowest quantity of pork obtained was from the balls of wheat, which is as low as 1 1-5 lb. from 1 decalitre. Flour would, no doubt, fatten better than wheat, especially if the feeds were made into small dry balls of dough and frequently administered, but better still, if made into bread of flour ground overhead.—*Ib.*

Profit from Thorough-Draining.

A farmer in Lanarkshire, whose name we are not at liberty to use, tried the effects of thorough-draining on a small field of four acres. Two acres of this field were drained in every furrow, the subsoil being retentive, but the upper soil was favorable to the growth of green crops. The other half was allowed to remain undrained, as the whole had been until the winter of 1837. In spring 1838, the whole field was worked for, and planted with potatoes. The potatoes were sold, and the result was, that the thorough-drained half yieded £45 an acre, whilst the undrained only realized £13 an acre. The drained land thus yielded about three and one-half times the undrained; and, supposing that the draining cost, at the utmost stretch, £10 an acre, the first crop, notwithstanding, not only repaid that cost, but left £22 an acre more than the whole crop per acre of the undrained land. What an encouragement does this simple fact and single instance of profit hold out to farmers to spare no expense and indulge in no hesitation in thorough-draining retentive-bottomed land? Although £45 an acre is a very large sum to obtain for an acre of potatoes, yet the crop was generally very deficient last year, and *good* potatoes were very scarce; but it must not be supposed that that amount was all profit, for the expenses of raising and driving the crop to market fall to be deducted from the value of the gross produce; still, £45 and £13 give the relative values of produce obtained from drained and undrained land. It is worthy of remark, that draining renders strong soil capable of raising a large green crop even in a wet season, whilst soil, in want of draining, is comparatively materially injured in a wet season. It is obvious that the soil here spoken of only required draining, to render it eminently qualified to raise green crops; and there is abundance of such soil in the country.—*Edinburgh Q. J. of Agriculture.*

Mode of Ascertaining the Milking Properties of Cows.

The French Agricultural Societies have been lately occupied in investigating the pretensions of a M. Guenon, who asserts that he can, by means of certain outward marks common to every cow, at once declare what quantity of milk she gives, of what quality it may be, and how long it will last after calving. In a late number of the *Annales de l'Agriculture Francaise*, we find the particulars of a report made to the Society of Agriculture at Rosoy, on an examination which took place of M. Guenon's system. The application of his plan was tried in the dairy of one of the chief proprietors of the place. It appears by the report, that out of 30 cows submitted to his examination, 25 were perfectly well described as to their milking qualities, and in the other 5, the differences from the truth were of such a nature, as to leave room for doubting whether they were not apparent rather than real differences. In two cases only was M. Guenon altogether in error. Afterwards, 20 milking cows were brought under his notice, and, in thirteen cases, his declarations agreed perfectly with those of the steward of the farm; three of the others to which he had attributed a greater quantity of milk than they really produced, were declared to have diminished from age, for which he, having made the examination with great rapidity, had not made any allowance.—With respect to two others, the steward was not able to declare positively as to the produce which they gave; for the other two, there were several quarts difference from the quantity named by M. Guenon.

In making his examination, M. Guenon more than once declared, that when he was required to name the quantity of milk exactly in measure, it might occur that his declaration was less than that which the animal produced, but that if the whole of the judgments which he gave were compared, it would be found that the relative proportions held good throughout the whole dairy. Besides, he does not maintain that he may not sometimes be in error; he thinks that it arises from the imperfect mode of applying the system, and not from the system itself. A circumstance occurred on this occasion, which serves to confirm the certainty of M. Guenon's judgment. He had to examine in a stable apart two heifers, of whose mothers he knew nothing: he declared that they ought to give certain quantities of milk, differing altogether from each other other, but agreeing perfectly with the nature of their mothers. An individual, not belonging to the farm, asked permission to bring in a cow whose produce he knew perfectly well, and of which he named beforehand, the quantity of milk, its continuance, and its quality. M. Guenon's account agreed in all parts with the person's statement. M. Guenon was afterwards taken to the farm of M. Gibert, and five cows were submitted to his examination. He was perfectly correct as to the quantity of milk they gave, and its duration; as to its quality, the servant who was in charge of the place, could not declare any thing with certainty. Amongst these cows was one which was an exceedingly bad milker; on her appearing M. Guenon uttered some exclamations on her beauty. The persons present thought he was on the point of making some mistake. On examining her nearer, he at once declared her not equal by half in produce to the rest, and retaining her milk for five months only. In both respects he was perfectly correct.

The following article appeared in the *Gardener's Gazette* of the 4th May last, which gives an account of the discovery of M. Guenon's, as far as it has been made known.

MODE OF JUDGING OF THE MILKING QUALITIES OF COWS.

The Minister of Public Works and Agriculture in France, was lately applied to by a M. Guenon, a landowner at Libourne, respecting a new method which he had discovered for classing the cows of every description, according to the quantity of milk which they can give per day, the quality of their produce, and the time they can keep it. The minister requested the Society of Agriculture to take charge of the necessary experiments to test the value of the discovery; and, in consequence, certain members were appointed to investigate the matter. M. Guenon, previous to his arrival at Paris, tried to obtain a remunerating number of subscribers to a pamphlet of his, containing full particulars of his discovery. When the total of the subscribed sums would amount to what he thought a sufficient reward for his secret, he proposed to send each subscriber a copy. This work he shewed at once to the gentlemen appointed by the society. In their report, they allude to the work, but very cautiously abstain from disclosing the mode of M. Guenon's procedure. They presented lately a report of what they did, from which we gain the following information:

M. Guenon's declaration goes so far as to assert that he can decide respecting the quality as well as the quantity of the milk. He asserts, besides, that his system applies to calves, no matter how young; so that, from examining one of the bovine race, he can predict with certainty the qualities which the animal, whether male or female, must be marked by. This part of his plan could not be tested, as it demands an examination extending to several years. M. Guenon gave an opinion before the gentlemen appointed by the society to act as a committee, on 149 cows giving milk, on 17 bulls and male calves, and 30 females. The whole experiments lasted four days. It would appear from the terms of the report, that M. Guenon, in deciding on the quantity of milk in those cases, only approximated, but did not often hit on the exact number of quarts. Out of the 149 cases, only 21 were exactly corresponding with the declarations of the owners of the cows. Also, in speaking of the time during which the cow holds her milk before calving, M. Guenon was seldom exact; the most he did was to come near the mark. On 2,573 quarts of milk given in three dairies, he was wrong in 514, or a fifth of the whole. The committee declare that the characters which serve as the foundation of the system are easy to be understood. The only fault they find is in the number of divisions and subdivisions which his system includes. First of all, he makes eight classes, and to each of these, the mark which serves as a guiding star may be varied frequently, according to the age and form of the animal. This gives eight subdivisions to each, which at once gives sixty-four different orders.—Again, in each of these there are three degrees, according to the age of the cows; so that we have thus 192 different kinds. But, omitting this drawback, it must be acknowledged that the character which directs him, and which is common to the whole of the race, must be considered of some value. He was incorrect in several instances, no doubt; but his method of deciding is new, and may be carried much farther. The sign by which he judges has been altogether unperceived up to the present time. In theory, it is such as may be admitted; and the presumption is, that it is of some value.

M. Guenon's discovery is applicable to every country, and the publication of his pamphlet is the only means of ascertaining (by a number of persons observing closely at the same time in different places) whether the method is as valuable as he asserts. One thing is certain, that he appears convinced that the principle upon which he judges is unerring. He acted most fairly and openly before the commission, and secured the approbation of each and all by his straightforward conduct. Their report may be thus summed up:—That the discoverer did not prove all he asserted, but the subject was worthy of further investigation. In pointing out bad milkers, M. Guenon was mistaken only in one instance, and then by omission rather than false declaration. At Rambouillet, there was one bad milker in the number, and that he pointed out at once; and at Alfort one which gave infinitely less milk than the rest was instantly discovered. The commission also declare that the mark by which he judges can be used approximately, in every form and every age.*—*Ib.*

Crossing the Musmon with the Sheep.

The Edinburg Quarterly Journal of Agriculture, says—"It is known that many naturalists, amongst others Cuvier, have presumed that the Musmon of Corsica (*Ovis Musmon*†) may be the stock from whence our domestic sheep have sprung. On this supposition, it would be a curious thing to ascertain if a reconcilement could be made between the wild and domesticated races of so useful an animal as the sheep."

"To attain this object, M. Durieu, receiver-general of the finances at Carcassonne," says M. Marcel de Serres, "has imported musmons from Corsica, and when a female of them has been in season, she has been put to a merino ram. These two animals, deprived of their liberty, and coupled, have produced a female cross, which was much more like the sire than the dam (that is the merino than the musmon). Indeed, this hybrid was no longer covered over with course reddish hairs, such as those which characterize the musmon; but only whitish wool scattered singly and at intervals among the coarse hairs.

"This female cross was then put to a pure musmon ram, and the produce obtained resembled, this time, much more the sire than the dam, (that is, the musmon than the merino). It was reddish coloured like the musmon, and bore only some woolly patches mixed among the reddish hairs, principally upon the neck. This produce was a male.

"This new cross was put to a female merino, and from that union resulted this time an individual of the male sex, which retained all the characters of its dam. Like her, he was covered with thick enough wool, through which were scattered here and there, reddish hairs, that reminded of its origin.

In all these crosses, obtained as we have stated, the limbs remained always naked, without wool as without hair, and it was the same with the under part of the body. The limbs were remarkable for strength, thickness, and vigor. Their habits also retained those of the musmons; at least those wild, savage crosses do not walk with a proper step, but almost always bound or leap. They also climb with as much ease as dexterity, and, when pursued, dart forward with nimbleness, and readily and quickly fall again upon their four feet.

"Such attempts at crossing are continued in order to ascertain the certainty of the crosses being prolific, and if they can be led back to a fixed type, whether to that of the musmon or the sheep. Those researches have another object, and that is, to ascertain, by means of crossings, whether the middling size of the merino can be enlarged, and a greater quantity of wool obtained.

"We may mention, that every attempt has been made to cross the he-goat in season, deprived of its liberty, with the female musmon in the same state, but every such attempt to overcome the aversion which they shew for each other has failed.

"It seems to result from these facts, that it is not always possible to triumph over the repugnance which different species feel against mutual crossing; and since the musmon and sheep do cross with one another, it is probable that both belong to one and the same species."—*Comptes Rendus, 15th October*, 1838.

Poudrette and Farm-Yard Manure.

M. Hermbstädt gives, in the monthly journal of the Economical Society of Potsdam, these as the results of his experiments instituted with the view of ascertaining the comparative fertilizing powers of farm-yard manure and poudrette, one of the new compound manures made in France, it is supposed, principally of night-soil.—*Ed. Q. J. Ag.*

"1. Poudrette is a perfect substitute for common dung, whether with respect to price or quality. 2. Its favorable effects essentially depend on the moisture of the season. 3. In dry years it is less efficacious upon sandy soils than upon very greasy or medium clays. 4. It is particularly suitable to very greasy clays. 5. By virtue of the lime and ammonia which it contains, it quickens and developes the inert humus, and the humic acid which often accumulates in the soil. 6. The poudrette combined with organic matter, or in the state it is actually made, is a powerful means of rendering clay land friable."—*Le Cultivateur for August*, 1838.

Extraordinary Crop.

We are informed that George C. Harness, Esq. of Hardy county, raised the past season, from *one acre of ground*, one hundred and seventy-eight bushels of corn. Mr. H. cultivated the same with a view for a premium at the approaching Agricultural Exhibition of Hardy county, and the husking and measuring of the corn was attended to by a disinterested, intelligent, and highly respectable citizen of Moorefield. This is the most extraordinary yield, from one acre of ground, that we have ever heard of. Truly, may the South Branch Bottoms, be termed the "garden spots of the Union."—*Romney Intelligencer.*

The Late Jesse Buel.

The following resolutions were unanimously adopted by the Northanna Agricultural Association, at its first meeting after the death of the late J. Buel, Esq. They would have been transmitted sooner for publication, but it was not known until the last number of the Cultivator was received, that the paper would be continued.

Resolved, That the public spirited, able and successful exertions of J. Buel, the late Editor of the Cultivator, to improve the agriculture of the country, have merited the highest praise, and entitled him to the gratitude of every friend of agriculture, and that this association deplores his death as a public loss.

Resolved, As a testimonial of the estimation in which we held him, and of our regret for his loss, that these resolutions be transmitted to the Cultivator, and the Farmers' Register, for publication.

W. HOLLADAY, *Sec'y.*
Spottsylvania co. Va. Nov. 18, 1839.

---

* Horticultural Journal for July, 1839.

† "This sheep, now, we may say, so comparatively little known, inhabits the mountainous wilds of Corsica and Sardinia, and has there only to contend against man as its enemy, no large carnivorous animals existing which would carry destruction among its herds; and it is to this circumstance probably that these islands are indebted to the remnant of the flocks which appear to have formerly existed among the mountains of Spain, and some neighboring parts of the continent of Europe.

"The flocks consist sometimes of a hundred or more, placed under the guidance of some old and courageous male. In a domestic state, the young males and females are docile and gentle; but the old males became subject to ill-natured fits, and sometimes assail children, women, and even men, attempting to bear them down by butting."—*The Naturalists' Library*, vol. iv. *Mammalia.—Editor Q. J. Ag.*

Young Men's Department.

The Close of the Year 1839.

(Written for the Cultivator.)

As the labors of the season draw to a close, it is natural and proper for us to take a review of the past, and examine our prospects for the future. The rapid flight of time has brought us to the termination of another year—a year fraught with interest pleasing and painful.

In taking a retrospective survey of the past, we may learn some very important lessons, to guide our course for the future. Three years since, we were all buoyancy and hope; the acquiring a fortune was then but the work of a day; a few successful operations in speculation, were to complete the climax of prosperity, and conduct whoever ventured to embark in it, at once to wealth and fame. The past year has been one of unparalelled commercial revulsion. We are now in gloom and despondency. Many have learned, by painful experience, that industry and frugality are the only avenues to wealth. We have learned that a fictitious value set upon property does not enhance its real worth.

Although many have suffered severely from this blight of their golden dreams, its influence, it is believed, will be beneficial rather than injurious to community. Not that we should rejoice over the calamities of any men; far from it; but when men venture beyond the soundings of reason, they must expect to bring up upon the lee shore of bitter experience. It will check in some degree the strong anxiety, so prevalent among us, to become *quickly* rich. It will convince us of the greater security of property acquired by persevering manual labor, over that accumulated by gambling speculation. It will hold up to our view, the vast importance of agriculture, and the dignity of its pursuit. It will teach us, it is hoped, effectually, that luxury and extravagance are the bane of prosperity, as well as of morality and honesty.

Notwithstanding the melancholy gloom which has spread so extensively throughout the land as to affect all classes of the community, the promise of the Great Ruler of the Universe, that "seed time and harvest should not fail," has this year been most bountifully fulfilled. Nature has not been unmindful of our wants; but, as if to show the superiority of her resources over those of commerce and the arts, we have occasion to rejoice over an unusual abundance of her productions, while the other branches of industry suffer an unusual depression.

In our recollections of the past, there is one event which we cannot but look upon as a public calamity—the death of the respected Editor of the Cultivator. The agricultural community, in particular, must feel severely the loss of one so zealous and so efficient in their cause. In him, the young found a faithful and disinterested counsellor: the farmer an able and practical adviser, and all a warm and generous friend. His energetic pen and extensive influence, were exerted for the agricultural and intellectual improvement of his countrymen. His great aim appears to have been to induce the yeomenry of his country to assume the rank, intellectually and morally, which they hold politically: to make the employment of agriculture more honorable, and success in its pursuit more certain—in a word, to render man better and happier. Cut off so suddenly in the midst of a career of so extended usefulness, his loss cannot but be felt by all who value the interest of their country, or the prosperity and happiness of their fellowmen.

The removal from the stage of action, of men so prominent for their usefulness, reminds us, as young men, of the duty of preparing ourselves to fill their stations. On us is soon to devolve the responsibility of giving cast to a nation's character:—to the character of a nation already occupying a conspicuous rank among the empires of the earth; one to which the eyes of all the world are turned, to mark its success or overthrow, in the bold course it has struck out for itself. It will depend on us, whether the free institutions of our happy Republic shall descend in all their original purity to succeeding generations, or whether man is yet to mourn the unsuccessful attempt to govern himself.

There appears to be springing up in our country the germ of principles antagonist to our republican institutions, and it would be well for us to take warning, and shun their evil consequences. Among these, I would mention a passion for extravagance, and aping the practices and manners of European aristocracy—a desire prevalent with the young particularly, to live without manual labor; and the idea that it is degrading to be employed in any kind of productive industry.

The destruction of most of the nations of antiquity, celebrated for the impartial justice of their laws, and the wisdom of their legislators, can be traced to luxury and extravagance. The celebrated historian, Rollin, says in his history of the Persians, "the most judicious historians, the most learned phiosophers, and the profoundest politicians, all lay it down as a certain, indisputable maxim, that whenever luxury prevails, it never fails to destroy the most flourishing states and kingdoms; and the experience of all ages and all nations does but too clearly demonstrate the truth of the maxim." We may boast the most profound statesmen, and the most wise legislators, but whether our nation is to maintain its rank among the most favored of the earth for prosperity and happiness, depends upon *ourselves.* As our government is constituted, we must govern ourselves well to make it a good government. If we fail here, there is no potency in our institutions to make us prosperous; no efficiency in our laws to render us happy.

The desire to be independent of manual labor—to be employed in some occupation more honorable, is becoming prevalent in our community. It perhaps arises out of our spirit of improvement—from our aspirations after greater and higher attainments; but its effects are prejudicial to our welfare and happiness, individually and collectively. I would not check the desire for improvement: it is only this unnatural tendency of it that I would correct. There is a dignity in industry aside from its usefulness, that should commend it to all. The situation of the industrious agriculturist, particularly, is one which all might desire. Yours, my young friends, is a noble pursuit. Allied to nature in her operations, your labors are amid her genial influences, to mould and direct her expanding forms to suit the wants of man. The All-Wise Creator has so formed our material frames, that labor is necessary not only to continue our existence, but to promote our happiness. We very much mistake our own welfare, therefore, if we would aim to live without it.

Thus much our public—let us now attend to our social and individual duties. Let us labor individually to cultivate those virtues which exalt human nature. Let us remember, that without self-improvement, there can not be general or mutual improvement. Let us labor to improve our intellects by making ourselves acquainted with the natural sciences—with the operations of nature, in the various departments of the physical, the vegetable and the animal world. If we once awaken our minds to what is boundless and vast in the physical world, by taking a view of the unnumbered suns that exist in the regions of space and the worlds that roll around them: to what is beautiful and harmonious in the vegetable world, by observing the form and proportions of plants, and the adaptedness of nature's means to the end in view; and to the symmetry and order in the animal world, by observing the agility of animals, and their fitness to the situations they occupy, and the circumstances under which they are placed; we shall be furnished with motive to still higher improvement—that of the moral and religious faculties: for it is believed, no man in his sober senses, can take a rational view of these sublime productions of nature, and not be convinced of his obligations to Nature's Great Author, and feel a desire to fulfil those obligations.

Without the cultivation of the moral and religious faculties, we fail to accomplish the great end of our being; for, as man stands highest in the scale of animal existences, so these faculties occupy the highest rank in the mind of man. His other faculties render him a noble animal; these assimilate him to God. It is a duty, therefore, we owe both to our Creator and to ourselves, to bestow upon the culture and development of these, more abundant attention. As the plants we value most, receive in proportion a greater share of our labor, so these faculties should be nurtured and cherished with assiduity proportionate to their importance.—Let us be reminded, by the events of the past years, that we are destined to an existence beyond the present, compared with which, in duration and importance, this dwindles into insignificance; and let us so act as most effectually to secure our greatest good, both here and hereafter. C. P. W.

Albany, December, 1839.

Chemical Catechism—Chapter IX.

[From Parkes' Chemical Catechism.]

OF SIMPLE COMBUSTIBLES—*concluded.*

Does carbon enter into any mineral combinations?

It is imagined that most of the metals may be combined with carbon: but at present we know only of its combinations with iron.

What does carbon form when combined with iron?

In one proportion it forms cast iron; in another steel; and in a third proportion plumbago, generally, though improperly, called black lead.(1)

What is the proportion of carbon in cast iron?

Upon an average, cast iron contains, according to the analysis of Bergman, about one forty-fifth of its weight of carbon.(2)

What quantity of carbon enters into the composition of steel?

Steel is iron, combined with about one part of carbon in two hundred of iron.(3)

How is carbon combined with iron so as to form plumbago?

Carburet of iron, or plumbago,(4) has been found to consist of nearly nine parts carbon to one of iron.

You said that carbon formed an acid by its union with oxygen: how is that effected?(5)

Carbon has so great an affinity to oxygen, that when assisted by heat, it will take it from most substances with which it may be combined; in certain proportions they then form carbonic acid gas.(6)

What quantity of oxygen is necessary to convert carbon into carbonic acid?

28 parts by weight of carbon require about 72 parts of oxygen to saturate them; so that 100 parts of carbonic acid are composed of nearly 28 parts of carbon and 72 of oxygen.(7)

What is the specific gravity of carbonic acid?

Carbonic acid can only be exhibited in the form of of gas; each cubical inch weighs about half a grain, 100 cubical inches having been found to weigh exactly 47.26 grains.(8)

What are the properties of carbonic acid gas?

Carbonic acid gas is invisible and elastic; is much heavier than atmospheric air;(9) will mix with vital air; may be combined with water, to which it gives a brisk and acidulous taste;(10) is destructive of flame, and will occasion the death of animals that are obliged to breathe it.(11)

---

(1) The name which plumbago has so long borne shows how necessary it was to give a new nomenclature to the science. It is now known that its metallic appearance is owing to iron; and that there is no lead in its composition. Many other instances might be adduced in which the names of substances have given false ideas of their nature and properties:—thus, white and green copperas contain no *copper*, but are formed the one with zinc, the other with iron.

(2) Cast iron does not owe its brittle qualities to the carbon which is combined with it; for that iron which contains most carbon is found to be the best metal. Cast iron generally contains some phosphuret of iron, and frequently a portion of oxygen: these substances give it its hard brittle quality. To convert cast iron into wrought iron the metal is submitted to a long intense heat, by which means, the carbon burns; and, uniting with the oxygen, both go off in the state of carbonic acid gas. The iron is then carried to the forge hammer, which beats out the phosphuret of iron, and brings the particles closer together. When the iron is required to be pure and good, it undergoes repeated hammering till it is brought to the desired quality.

(3) To procure steel, nothing more is necessary than to heat good pure iron for several hours in a proper furnace, with charcoal, or any substances proper for furnishing a sufficient quantity of carbon, which is absorbed by the iron in the process. Iron has so great an affinity for carbon, that it is even capable of decomposing carbonic acid in a high temperature. See *Philosophical Magazine*, vol. ii. where there is an account of a late mode of making steel by fusing soft iron in crucibles with carbonate of lime. The diamond, which is pure carbon, will also convert iron into steel. This was proved by the ingenius Mr. Children, who enclosed a diamond within a slit which he had made in one end of a large iron wire, and having submitted it to the action of galvanism, the diamond disappeared, and the iron was found to be changed into steel.

(4) Plumbago is found in great plenty, at a place called Borrowdale, in Cumberland. Besides making pencils, it is likewise useful to rub over wooden machinery, to prevent friction.

According to Fabroni, plumbago is formed in the humid way, at the bottom of certain wells in the kingdom of Naples, from whence it is regularly collected every six months.

Carburet of iron is found also in various parts of the continent. It often occurs in mountains, in the midst of beds of quartz, or calcareous earth. It has sometimes been found crystallized in octahedrons.

Plumbago, like charcoal, is indestructible by heat, unless with the presence of atmospheric air. It is therefore much used for making crucibles and portable furnaces. It protects iron from rust, and on that account is rubbed on various ornamental cast iron works, such as the fronts of grates, &c.

(5) Take one of those glass receivers generally used for deflagrating the gases; fill it with oxygen gas, and invert it in a shallow pan of water. Then having a piece of ignited cortical part of charcoal ready, suspend it by a wire to the stopper of the receiver, and immerse it quickly in the gas. The charcoal will be seen to burn for a considerable time with the greatest splendour, throwing out the most beautiful coruscations. When the inflammation is over, the oxygen gas will be consumed, and the water will be found to be impregnated with carbonic acid; and if some transparent lime-water be poured in, the whole will become opaque from the carbonate of lime now formed.

(6) There can be no doubt that carbonic acid is formed by the union of carbon with oxygen; for steel may be made as effectually by the decomposition of carbonic acid, as it can by the direct union of iron with carbonaceus matter.

Carbon takes a gaseous form also by combining with hydrogen and caloric, and forms what is called carburetted hydrogen gas; likewise in the gas discovered by Dr. Priestley, and which Mr. Cruikshank named the *gaseous oxide of carbon.*

(7) Oxygen has a greater affinity for carbon than for most other substances. Lavoisier burned small quantities of charcoal in pure oxygen gas in close vessels, and found that a part of this gas was converted into fixed air, or carbonic acid. He separated this from the rest of the oxygen by means of caustic alkali, and weighed the alkali after it had attracted the fixed air. He also expelled the air again by an acid, and examined its bulk. Thus he learned the weight of the air, and what measure of it had been produced. Then, comparing this weight with that lost by the charcoal which had been consumed, he found it to exceed greatly the weight of the charcoal; and that it was exactly equal to the weight of the charcoal added to that portion of the oxygen gas which had been changed into fixed air. Dr. Black's *Lectures on Chemistry*, vol. ii. page 100.

The composition of carbonic acid has been further proved by analysis, as it has actually been decomposed, and the charcoal exhibited entire. See Mr. Tennant's experiments on fixed air, in *Philosophical Transactions*, vol. lxxxi. page 181. When a diamond is burnt, the proportions are similar to the above, for diamond is the purest carbon we are acqainted with.

Carbonic acid gas may be readily procured for experiment by pouring a little diluted sulphuric acid into a phial, or a retort, upon a little pulverized chalk. An action will immediately commence; and if one end of a bent tube be made fast in the neck of the phial, and the other brought under the mouth of a jar filled with water, and inverted in a vessel of water, the gas will pass from the mixture into the inverted jar.

(8) When charcoal is burnt in oxygen gas, every 100 cubical inches of the gas, which originally weighs 33.75 grains, will then weigh 47.26 grains; and as the gas acquires no alteration in volume, this shows that 100 cubical inches of oxygen will combine with 13.51 of charcoal.

(9) This gas, on account of its density, may be poured from one vessel to another, like water; or may be drawn from a cask by a cock like other fluids. In consequence of its great

In what state does carbonic acid exist in nature?

Carbonic acid is found in three different states, viz. in gas, in mixture, and in chemical combination: it is, perhaps, the most abundant of all the native acids.(12)

What instances are there of its natural existence in the state of gas?

It is found in the proportion of about one part by measure in every thousand parts of atmospheric air; also in caverns and mines where it is called the choke-damp.(13)

What instances are there of carbonic acid being found mixed with fluids?

It is abundant in Spa-water, and in some other acidulous waters.(14)

In what substances is carbonic acid found chemically combined?

Carbonic acid is found in all parts of the world in great plenty, in combination with the alkalies, with some metallic oxides, in earths, and in stones; particularly in chalk, limestone and marble.(15)

What is the effect *of the combination of carbonic acid?*

Carbonic acid renders mild and salutary some of the most acrid and destructive of all known substances.(16)

How is the carbonic acid separated from the alkalies and earths?

Carbonic acid may be disengaged by most of the other acids; but it is usually separated from alkalies by the addition of quick lime, which absorbs this acid, and thus is converted into carbonate of lime.(17)

How is carbonic acid usually procured for chemical purposes?

Carbonic acid gas may be collected in abundance from the surface of fermenting liquors; but it is more commonly obtained by pouring sulphuric acid upon a mixture of chalk, or marble and water.

How do you account for the production of carbonic acid gas in the process of fermentation.

In all vinous fermentations a decomposition of the saccharine matter takes place; and a part of the disengaged oxygen, uniting with a part of the carbon of the sugar, forms carbonic acid. A decomposition also of a part of the water of solution perhaps promotes the process.

What is the cause of vinous fermentation?

The cause of vinous fermentation is not well understood; though it is a process which nature employs and which art can imitate, for the decomposition of certain vegetable substances,(18) (when in favorable circumstances of temperature and solution,) and also for their recomposition to form new products.

What circumstances are necessary to produce vinous fermentation?

The presence of vegetable matters, of water, of sugar,(19) a certain degree of heat, and free escape for the carbonic acid as it is generated.(20)

Can you at all account for the change which is effected in saccharine liquors by fermentation?

By the process of fermentation the sugar, which is a vegetable oxide,(21) parts with a portion of its oxygen to form carbonic acid, and becomes converted into alcohol(22) by being thus partially deoxidized.

Does sugar then become spirit of wine, or alcohol, merely by losing a part of its oxygen?

No: it parts with a portion of its carbon at the same time, in the form of carbonic acid gas, and a new arrangement of the principles, both of the sugar, and of the water in which it is dissolved, taking place, furnishes an increased proportion of hydrogen, in order to form vinous liquor.(23)

Endeavor to recollect the different properties of charcoal, which you have enumerated in this chapter.

Charcoal appears to be indestructible by age; it is not in the least altered by the most intense heat, if heated in *closed* vessels; when burnt in atmospheric air it becomes converted into carbonic acid gas; it is a valuable antiseptic; it is the basis of all vegetables; it is one of the component parts of wax, oils, gums, and resins; and from its affinity to oxygen it has the property of decomposing many substances in which oxygen constitutes a material part.

How did chemists become acquainted with all these properties of charcoal?

Formerly, nothing was known of charcoal but its indestructibility and its antiseptic qualities. The other peculiar and surprising properties of charcoal were reserved for the discoveries of the present age; for these we are most especially indebted to the labours and genious of Black,(24) Priestly,(25) Cavendish, Lavoisier, Guyton, Tennant and Berthollet, and to the gradual development of the present improved system of chemistry.

What reflections naturally present themselves on the consideration of the various properties of charcoal and the other simple combustibles?

This subject, when considered in all its connexions, is calculated to produce the most profound admiration; and serves to convince us of the unbounded comprehension of the Divine mind, which, in the act of creation, could foresee and appoint such important effects to result from the combinations and changes of the most inodorous and insipid substances. We also learn, that all the works of the Creator are perfect; and perceive with astonishment, that they are composed of elements which are in themselves incapable of destruction.

---

specific gravity it is frequently found at the bottom of mines, wells, &c.

(10) In order to saturate water with this gas, it is necessary to subject it to a considerable degree of pressure. The persons who are engaged in making the acidulous soda water have peculiar conveniences for this purpose. Cider, perry, bottled beer, and other fermented liquors, owe their briskness and sparkling to the presence of this gas.

(11) Carbonic acid has also the property of rendering lime soluble in water. As the carbonic acid escapes by exposure to the air, the calcareous matter is precipitated from the water which held it in solution; whence arise the various earthy incrustations found in different parts of the world. Fourcroy has very aptly remarked, "that when natural history was less enlightened by chemistry, springs of this kind were called *petrifying* waters, and were by the vulgar reckoned among the number of miracles.

(12) Plants of all kinds give out carbonic acid gas, while growing in the shade: but when assisted by the rays of the sun, there is reason to think, that the plants have the power of decomposing this acid; for then the leaves give out only oxygen gas. *Annales de Chimie*, tome xiii. page 318.

Mons. Saussure has shown, that when vegetables decompose carbonic acid gas, they throw off only half of the oxygen; and that the other half, with the whole of the carbon, enters into the composition of the plant. He also says, that the leaves absorb oxygen gas in darkness, and emit an equal quantity when exposed to the light. If this account of vegetation be correct, growing vegetables deteriorate the atmosphere in the night, and purify it in the day. The roots, wood, and petals perform no inspiration. See *Philosophical Magazine*, vol. xx. page 308.

(13) The floor of the Grotto del Cane, in Italy, is lower than the door, and this hollow is always filled with fixed air, which can rise no higher than the threshhold, but there flows out like water. It has been a common practice to drive dogs into this cavern, where they suffer a temporary death for the entertainment of the passengers; but a man enters with safety, because his mouth is far above the surface of this deleterious air. From the loss of so many dogs, in this cavern, it acquired the name of the Grotto del Cane. The lake of Averno, which Virgil supposed to be the entrance to the infernal regions, evolves so large a quantity of this gas, that birds, flying over it, drop with suffocation.—Fatal accidents have happened to persons who have incautiously descended into brewers' vats and wells, before they have been purified from this gas.

Carbonic acid gas so often occupies the bottoms of wells, that workmen ought never to venture into such places without previously letting down a lighted candle. If the candle burns they may enter it with safety; if not, a quantity of *quick-lime* should be let down in buckets, and gradually sprinkled with water. As the lime slakes, it will absorb the carbonic acid gas, and the workmen may afterwards descend in safety.

Fatal accidents often happen from burning charcoal in chambers; because wherever charcoal is burned this gas is always formed. Workmen have also lost their lives by sleeping too near lime-kilns, where this gas is extricated in abundance. Whenever persons are discovered in such situations, or are suffering from the effects of carbonic acid gas, the same means should be made use of as are directed by the Humane Society in cases of apparent death from drowning: or when it can be done without loss of time, atmospheric air, or even pure oxygen gas, should be forced into the lungs. I have known galvanism sometimes employed in such cases with the best effects.

Dr. Henry has suggested to naturalists, that butterflies and other insects, the colours of which it is desirable to preserve, for the purpose of cabinet specimens, may be suffocated in carbonic acid gas, better than by the common mode of killing them with the fumes of sulphur.

(14) These waters have a pleasant light acidity and briskness, and sparkle in the glass, like fermented liquors; which is well known to be the case with water, when artificially impregnated with fixed air. Dr. Percival esteems it highly medicinal in pulmonic consumptions, and in malignant fevers.

By great pressure, water may be combined with more than twice and a half of its own bulk of carbonic acid gas. Such waters are considerably more acidulated than those afforded by nature, and have much greater medicinal effects.

(15) Carbonic acid is found combined with alkalies, and with several metallic oxides. These combinations are called carbonates.

A cubic inch of marble contains as much carbonic acid in combination as would fill a six gallon vessel, when in the state of gas.

(16) We all know the causticity of pure quick-lime, and the corrosive qualities of the fixed alkalies; but whenever these substances are *fully* saturated with carbonic acid, the first forms mild calcareous earth (or chalk,) and the others mild neutral salts, applicable to many purposes of medicine and domestic economy.

(17) Though the alkalies readily part with their carbonic acid to caustic calcareous earth, yet they have a great affinity to this acid, as may be shown by the following interesting experiment:—Fill a jar with carbonic acid gas, then pour into it a small quantity of a solution of *caustic* potash or soda; and having tied the mouth over with a wetted bladder, move the vessel so as to spread the alkali over its inner surface, when a vacuum will be quickly formed by the absorption of the gas, which will appear by the bladder being pressed inwards by the weight of the atmosphere. If this experiment be made in a glass vessel, its surface will be seen covered with crystals of the alkali, as the carbonic acid always promotes the crystallization of the fixed alkalies.

(18) Fourcroy admits five distinct species of vegetable fermentation, viz. the saccharine (or that which forms sugar,) the vinous, the acetous, the colouring (or that which is developed by the maceration of the indigo plant,) and the putrid. See Fourcroy's *System of Chemical Knowledge*, vol. viii. page 148. Some writers have spoken of another kind of vegetable fermentation, viz. the panary, or that which manifests itself in making bread; but surely this is a species of the acetous, for its tendency to acidify is very evident.

(19) It appears from several late experiments carefully made, that sugar is composed entirely of hydrogen, oxygen and carbon. Mr. Cruickshank made many experiments on fermentation, and invariably found, that whenever he added a fourth substance to the three which compose saccharine matter, no fermentation took place. He tried lime, and at another time a small quantity of potash; and the addition of either prevented fermentation.

(20) To produce vinous fermentation, it is necessary that the matters subjected to that process should be placed in a temperature not lower than about 55 degrees of Fahrenheit. No kind of fermentation is ever known below the freezing point.

(21) Lavoisier, having analyzed sugar, found that it was composed of hydrogen, oxygen and carbon, in the following proportions:—Hydrogen 8lbs. oxygen 64lbs. carbon 28lbs. in every 100 pounds weight of sugar. Lavoisier's *Elements of Chemistry*, page 188. Having subjected 100lbs. of sugar to fermentation, he found the products (alcohol, carbonic acid, and acetous acid,) when analyzed, contained the precise quantities of hydrogen, oxygen and carbon, which were contained in the original sugar. The particular detail which he has given of these experiments is extremely interesting. Ibid, page 185 to 197. In consequence of the results which were obtained, he remarks, "The effect of the vinous fermentation upon sugar is thus reduced to the mere separation of its elements into two portions: one part is oxygenized at the expense of the other, so as to form carbonic acid; while the other part being deoxygenized in favor of the former, is converted into the combustible substance called alcohol." Ibid, page 196. The strongest alcohol of commerce is seldom of a less specific gravity than that of 0.825. Proof spirit, or the spirit of wine employed in pharmacy, has a specific gravity of 0.930.

(22) Alcohol, according to the analysis of Lavoisier, is composed of

Carbon about - - - 30 parts.
Hydrogen, - - - - 7.5 parts.
Water, - - - - - 62.5 parts,
100.0

But as this analysis was made by burning alcohol in oxygen gas, it is probable that the greater part of the water was formed during combustion. Hence the real component parts of alcohol are not accurately known.

(23) The spirituous or intoxicating quality of all fermented liquors is owing to the alcohol they contain, whether it be malt-liquor, wine or spirits. Alcohol expands by slight degrees of heat more than any other fluid;—hence the propriety of employing it in forming thermometers. The same degree of heat which expands glass *one* degree will expand alcohol 180 degrees.

Alcohol has various uses in pharmacy and chemistry. It dissolves the resins and volatile oils. Hence its employment in the preparation of spirit varnishes. It is employed also in chemistry, in separating those salts from each other which cannot easily be separated by any other means. It dissolves the oxalic, tartaric, and some other acids. The salts which are dissolved in the greatest quantity by alcohol are the muriates of magnesia and of lime, and the several nitrates of magnesia, lime, alumina, ammonia, and soda.

(24) In the year 1755, Dr. Black discovered the acid gas which is thrown off from fermented liquors and from mild calcareous earth. He called it fixed air.

(25) Dr. Priestly explained the effect of charcoal in decomposing nitrous acid, examined the gas that is thrown off in this decomposition, and pointed out the necessity of distinguishing the different gases from common air; for which the Royal Society awarded him an honorary prize.

In the years 1766 and 1767, Mr. Cavendish published papers in the *Philosophical Transactions*, on the nature of elastic fluids, in which he announced that he had produced fixed air by the burning of charcoal. This assurance called the attention of all chemists to that surprising substance, and was the forerunner of the many discoveries which have since been made respecting its properties, &c.

Lavoisier pointed out the nature of the action of charcoal in reducing metallic oxides; investigated the nature of the combustion of the diamond; announced the exact quantity of carbon in carbonic acid, and the production of carbonic acid by the decomposition of water with ignited charcoal.

Prospectus of the Cultivator, Vol. VII.

A CONSOLIDATION OF

Buel's "Cultivator" and the "Genesee Farmer."

Willis Gaylord and Luther Tucker, Editors.

Jesse Buel & Co. Proprietors.

THE first number will be issued in January, 1840, at which time all existing subscriptions will terminate, and the paper will be discontined, unless the subscriptions shall have been or are renewed. The price, as heretofore. will be *One Dollar* a year, payable in advance. Postmasters, agents and others, who will obtain subscribers, and transmit the subscription moneys free of charge, will be allowed commissions at the following rates:

For ten subscribers or over, - - - -	10	per cent.
twenty or over, - - - - - -	15	"
fifty or over, - - - - - - -	20	"
one hundred or over, - - - - -	25	"

On ten or more copies for schools, or agricultural premiums, a discount will be made of 33 per cent.

It has been decided by the Postmaster-General, that postmasters have the right to enclose money to the publishers of newspapers, for third persons. This liberal construction of the post-office law, we hope, will induce postmasters to take an interest in the circulation of the Cultivator, which we may assume, without vanity, will tend to improve agriculture wherever it circulates, and consequently to benefit the neighborhood.

The publication of the Cultivator was commenced at 25 cents per volume; the price was afterwards advanced to 50 cents, and at the commencement of the fifth volume, to one dollar per annum. It is due to our patrons and ourselves to explain the cause of this increase in price. The size of our pages has been enlarged, the quantity of matter increased, and the quality of the paper improved, until the expense of type-setting and paper, the two prominent items of our expense, is now more than double what it was when the price was fifty cents, and four times as great as it was when the price was but twenty-five cents. To enable the reader to judge of its now relative cheapness, compared with literary periodicals, we state for their information, that a volume of the Cultivator, including its usual extra sheet, contains about double the quantity of matter that is contained in two volumes (published in a year) of the North American Review. The subscription price of the two volumes of the Review is five dollars—that of the Cultivator one dollar. To be equal, in proportion to the quantity of matter, the price of the Cultivator should be ten dollars a year.

We are enabled only to print the Cultivator at this small price, from the extent of our subscriptions; and we are indebted for our liberal subscription to the kind offices of our correspondents and agents. To these we tender again our hearty thanks, and respectfully invite a continuance of their favors, both in behalf of the publishers and their patrons.

No papers will be forwarded to any subscriber, unless paid in advance, either to the proprietors, or to their authorized agents.

Should any gentleman to whom the Prospectus may be sent lack leisure to present it to his neighbors, he will do us a favor, and we think a public service, by placing it in the hands of some one who will take an interest in soliciting subscriptions.

☞ Agents will please number the subscribers whose names they send us, from one onwards, the more readily to determine the total, and to assist in keeping accounts correct.

To meet the public demands, we have published a new edition of our four first volumes, which may be had, stitched, at 50 cents per volume, and also in different forms of binding, with the addition of the binders' charge. Bound copies have been forwarded to our agents in Boston, New-York. Philadelphia, Baltimore, Washington, Alexandria, Richmond, Savannah, New-Orleans, St. Louis, Nashville, Hartford, Utica, Greensboro', Ga. and Norfolk, Va.

☞ If it is noted by punctual agents, that any subscriber wishes his paper continued *till forbid*, it will be so continued, the agent holding himself responsible for the subscription.

In our next volume, we intend to dispense with advertisements, and print a semi-annual or quarterly advertising sheet, providing sufficient encouragement is given.

TO SEEDSMEN.—A young man who has been engaged in the seed business for a number of years, wishes to obtain a situation in a similar establishment. He is thoroughly acquainted with the business in all its branches, and can furnish testimonials from his last employer as to capability, and a line addressed to R. S. care of Wm. Thorburn, Seedsman, Albany, N. Y. will meet with attention. Albany, Dec. 1st, 1839. 1t

---

FRUIT and ORNAMENTAL TREES, ROHAN POTATOES, &c.—An extensive assortment of the finest varieties of Fruit Trees, and Ornamental Trees of large size. A fine collection of Herbaceous Plants, Pæonies, Roses, &c. 80,000 genuine Morus Multicaulis of large size, the growth of Virginia. Also, 1,000 bushels Rohan Potatoes. Orders addressed to the subscriber will receive prompt attention.

Newton, (Mass.) Dec. 1, 1839. JOHN A. KENRICK.

MORUS MULTICAULIS.—25,000 trees for sale, either in quantities or all together, and to be delivered at any time that may best suit the purchaser. They are from imported cuttings, of the genuine Morus Multicaulis, were planted in May last, and are of the most vigorous growth, measuring from three to five feet in heighth, with large collateral branches. Purchasers are invited to call and see them, at the residence of Gen. Morgan Lewis, Staatsburgh, Dutchess county, state of New-York, where the owner lives, as he thinks they will not suffer by a comparison, with any in the United States. Staatsburgh, Dutchess co. Sept. 11, 1839. [oct. 4t] MATURIN LIVINGSTON.

ALBANY NURSERY.—This establishment now offers perhaps the best collection of Pears now in the country; [see the June number of the Cultivator.] Also, Apples, Peaches, Plums, Ornamental Trees, Green-House Plants, &c. &c. A catalogue will soon be printed, and forwarded to order. Address J. BUEL & Co. post-paid. tf

---

HARPERS' SCHOOL DISTRICT LIBRARY, second series—price $20, including a case. From the Hon. John C. Spencer, Secretary of State and Superintendent of Common Schools.

Office of Superintendent of Common Schools,
Albany, October 30, 1839.

Messrs. Harper & Brothers—Gentlemen—I have received the second series of the School District Library, published by you, and have carefully examined it. It gives me great pleasure to express my entire approbation of the books individually, and of the selection as a whole. A large number of excellent books may be easily found in our language; but to select only a small number of forty or fifty in reference to the wants and taste of the community, so that they shall embrace subjects sufficiently various to interest and yet impart the largest amount of instruction, is a task of much difficulty. This you have accomplished. And I feel bound to say, that I consider this series superior to any other collection, for the same purpose, within my knowledge. While you have consulted novelty in having some original works, you have not sacrificed utility, but have studied to promote it. The cheap price at which it is afforded is, I believe, entirely unparalleled. No person who purchases it, either for a district circulating library or for his family use, will ever regret the bargain.

I cannot forbear acknowledging the spirit and enterprise which have carried on and completed the publication of these books in time to enable the school districts to procure them before the navigation of the canals is closed. Very respectfully, your ob't serv't. JOHN C. SPENCER.

51, 52. *Life and Works of Dr. Franklin*, with a portrait on steel; new edition; in 2 vols.

53, 54. *The Farmer's Instructor;* consisting of essays, practical directions for the management of the farm, garden, &c. By the Hon. Judge Buel; with engravings; in 2 vols.

55, 56. *The Pursuit of Knowledge under Difficulties;* its pleasures and rewards; illustrated by memoirs of eminent men; in 2 vols.

57. *Animal Mechanism and Physiology;* being a plain and familiar exposition of the structure and functions of the human system; designed for the use of families and schools; by J. H. Griscom, M. D.: illustrated by numerous engravings.

58. *The Elephant* as he exists in a wild state and as he has been made subservient in peace and in war, to the purposes of man; illustrated by numerous engravings.

59. *Vegetable Substances used for the food of Man;* illustrated by numerous engravings.

60, 61, 62, 63, 64, 65. *Universal History*, from the creation of the world to the decease of George III. 1820; by the Hon. Alexander Fraser Tytler and Rev. E. Nares, D. D. ; edited by an American: in 6 vols.

66. *Illustrations of Mechanics;* by Professors Moseley and Renwick; with numerous engravings.

67. *Narrative of Discovery and Adventure in the Polar Seas and Regions;* by Professors Leslie and Jameson, and Hugh Murray, Esq.; with maps, engravings, &c.

63, 69. *Paley's Natural Theology*, with illustrative notes; by Henry Lord Brougham, F. R. S. and Sir Charles Bell, K. G. H., F. R. S., L. & E.; with numerous woodcuts; to which are added preliminary observations and notes, by Alonzo Potter, D. D.; in 2 vols.

American Biography—Edited by Jared Sparks, Esq. viz.

70. Life of John Stark, by Edward Everett. Life of Charles Brockden Brown, by William H. Prescott. Life of Richard Montgomery, by J. Armstrong. Life of Ethan Allen, by Jared Sparks. With a portrait.

71. Life of Alexander Wilson, by William B. O. Peabody. Life of Captain John Smith, by George S. Hilliard. Portrait.

72. Life and treason of Benedict Arnold, by Jared Sparks, Esq. Portrait.

73. Life of Anthony Wayne, by John Armstrong. Life of Sir Henry Vane, by C. W. Upham. Portrait.

74. Life of John Eliot, the apostle to the Indians, by Convers Francis. With a portrait.

75. Life of William Pinkney, by Henry Wheaton. Life of William Ellery, by E. T. Channing. Life of Cotton Mather, by Wm. B. O. Peabody. With a portrait.

76. Life of Sir William Phips, by Francis Bowen. Life of Israel Putnam, by O. W. B. Peabody. Memoir of Lucretia Maria Davidson, by Miss Sedgwick. Life of David Rittenhouse, by James Renwick. Portrait.

77. Life of Jonathan Edwards, by Samuel Miller. Life of David Brainard, by Wm. B. O. Peabody. Portrait.

78. Life of Baron Steuben, by Francis Bowen. Life of Sebastian Cabot, by Charles Hayward jr. Life of William Eaton, by Cornelius C. Felton. With a portrait.

79. Life of Robert Fulton, by Professor Renwick. Life of Henry Hudson, by Henry R. Cleveland. Life of Joseph Warren, by Alexander H. Everett. Life of Father Marquette, by Jared Sparks. Portrait.

80. *The Travels and Researches of Alexander Von Humboldt;* by W. Macgillivray, A. M. with engravings.

81. *The History of Greece;* by Dr. Goldsmith. Prepared by the author of "American Popular Lessons," &c.

82. *Natural History of Birds;* their architecture, habits, &c. with numerous engravings.

83. *Familiar Illustrations of Natural Philosophy*, selected principally from Daniell's Chemical Philosophy; by James Renwick, L. L. D. with numerous engravings.

84, 85. *Selections from the Spectator;* embracing the most interesting papers by Addison, Steele, and others; in 2 vols.

86. *The Elements of Geology*, for popular use; containing a description of the geological formations and mineral resources of the United States; by Charles A. Lee, A. M., M. D. Numerous engravings.

87. *The History of Rome;* by Dr. Goldsmith. Edited by H. W. Herbert, Esq.

88. *A Treatise on Agriculture;* comprising a concise history of its origin and progress; the present condition of the art abroad and at home, and the theory and practice of husbandry; to which is added a dissertation on the kitchen and fruit garden. By Gen. John Armstrong; with notes by the Hon. Judge Buel.

89. *Natural History of Quadrupeds;* numerous engravings.

90. *Chaptal's Chemistry applied to Agriculture;* a new translation, with valuable selections from Sir Humphrey Davy and others.

91. *Lives of the Signers of the Declaration of Independence;* by N. Dwight, Esq. One volume, large 12mo.

92, 93, 94, 95. *Plutarch's Lives;* translated from the original Greek; with notes, critical and historical; and a life of Plutarch. By John Langhorne, M. D. and William Langhorne, M. A. Carefully corrected, and printed from the last London edition. In four large 12mo. volumes.

From his excellency W. L. Marcy, late Governor of the state of New-York, dated "*Albany, October* 29, 1839."

"Messrs. Harper—Gentlemen—I have availed myself of the opportunity you have afforded me, to examine the second series of the School District Library; and though I thought the *first* a very judicious and appropriate selection. I am inclined to believe the *second* preferable to it. Some of the books contained in it I have never read, but the subjects of which they treat are such as should in an especial manner be presented to the class of readers for which the library is intended.

"The introduction of libraries into our district schools is a new and highly valuable feature in the system of popular education. The character of the books which you have published for this purpose. and the low price at which they may be obtained, must, I think, facilitate the establishment of such libraries. I sincerely hope that you will meet with sufficient encouragement to induce you to continue the series. I am with great respect, your obedient servant,

"W. L. MARCY."

The above, together with the *First Series*, are for sale by all the principal Booksellers throughout the state.

☞ **MORUS MULTICAULIS AND OTHER** MULBERRIES, &c.—The subscriber is now ready to receive orders to any reasonable amount, for trees of the Morus Multicaulis, or cuttings of the same. The trees are genuine, all being raised by the subscriber, either at his nursery here, or at his *Southern establishment at Portsmouth, in Lower Virginia.* Also, the Elata, Broussa, Canton and Moretti or Alpine, &c.

The collection of Fruits is of the most celebrated kinds. The catalogue of *Fruit and Ornamental Trees and Shrubs, Roses and Herbaceous Plants, for* 1839, is ready, and will be sent to all who apply. In that catalogue, the very best kinds of fruits, so far as proved, are particularly designated by a *star*. All orders will be promptly attended to: and trees, when so ordered, are securely packed for safe transportation. Nonantum Hill, Newton, Mass. 7th October, 1839.

t jan. WILLIAM KENRICK.

MULBERRY TREES.—25,000 Multicaulis, Alpine and Expansa Mulberry trees, and a few thousand Silk Worms Eggs, for sale by S. E. GIBBS & SON,

Address them at Brooklyn. October, 1839. 3t.

MULBERRY TREES.—A few thousand Mulberry Trees are for sale at the Albany Nursery. They consist of the Multicaulis, Brussa, Chinese, that is, the product of Chinese seed, and the common white. The prices will depend upon size and quality. The Brussa is more hardy than the common, and the Chinese about as hardy; and the three kinds are believed to be equal, if not superior, to the Multicaulis, for silk; though it is proper to add, none of the mulberries that we have tried are propagated with so much facility, from buds and cuttings, as the multicaulis. The prices will be conformed to the average market price. tf

---

ROHAN POTATOES.—The subscriber is now prepared to furnish the above very valuable root for transportation, at $5 pr. bbl. until the 1st Nov. delivered at Albany. Persons living at a distance, will find it to their interest to forward their orders early, so they will reach their destination before cold weather sets in. Orders enclosing five dollars, (postage paid) or more, will meet with immediate attention.

CALEB N. BEMENT.

Three-Hills Farm, Albany, Oct. 1*st*, 1839.-3t

☞ **ROHAN POTATOES.**—Orders received for Rohan Potatoes, at $5 per Barrel, to be forwarded, as may be directed, without delay, by J. BUEL. tf

---

THE FARMER'S COMPANION, or Essays on the Principles and Practice of American Husbandry; with the Address prepared to be delivered before the Horticultural and Agricultural Societies of New-Haven County, Conn.; and an Appendix containing Tables and other matter useful to the Farmer, by the late Hon. Jesse Buel; this day published and for sale by MARSH, CAPEN, LYON & WEBB, No. 109 Washington-street, Boston.

FLORA'S INTERPRETER.—A new edition, this day published by MARSH. CAPEN, LYON & WEBB, No. 109 Washington-street, Boston.

IMPORTED CATTLE—BERKSHIRE PIGS.—The subscriber intending to return to England, offers for sale his stock of Imported Durham Short Horned Cattle and Berkshire Pigs, at his residence, English neighborhood, Bergen county New-Jersey, five miles from New-York. The stock consists of 15 head of milking cows, 1 two-year old heifer, 4 one-year old heifers, and from 8 to 10 spring calves. Four of the above cows are imported, and the remainder are got by the imported Herd-Book Bulls Dishley, Durham, Wye-Comet, Hall's Comet, Memnon, Admiral, Denton, &c.

BERKSHIRE PIGS.—Ten breeding Sows, in pig and with pigs by them at the present time; from 40 to 50 Pigs ready for delivery at any time, at prices from $10 to $20 per pair, delivered in New-York.

The imported Herd-Book bred bull Bloomsbury is with the Cows for the season, and from present appearance will soon all be in calf. The yearlings and spring calves are all by my bull Snow-Ball, late Minevis, by Wye-Comet, dam Nelle, bred by Israel Munson, Esq. of Boston, got by the imported bull Admiral; grand-dam Rosa, bred by Mr. Munson, by the imported bull Denton, owned by Stephen Williams, of Northborough, Mass.: great-grand-dam Tuberose, bred by Mr. Wetherall, and imported by Mr. Munson.

For further particulars, see Herd-Book; Dishley, page 63; Durham, page 567; Wye-Comet, page 200; Admiral, page 2; Denton, page 43; Tuberose, page 524.

BENJAMIN BRENTNALL, English neighborhood,
sept-3t. Bergen co. N. J. 5 miles from N. Y.

FROM THE STEAM PRESS OF
C. VAN BENTHUYSEN,
ALBANY, N. Y.

☞ **Note Well**—The pages numbered 213 to 220 are to be cut out and placed at the end of the Volume, and the remainder in front.

CULTIVATOR ADVERTISING SHEET.

FARMERS' DIRECTORY.

We give below, according to promise, such references as have been forwarded to us, of venders of FARM STOCK, FARM IMPLEMENTS, FARM and GARDEN SEEDS, and of PUBLIC NURSERIES. Its advantages to the public at large, even on this limited scale, will be apparent to all; but we hope another year to be furnished with the means of greatly enlarging and improving it.

Venders of Farm Stock, &c.

JOHN COWLEN, Truxton, Cortland, N. Y. Imported New-Leicester Sheep, Bucks and Ewes.

SAMUEL LOOK, West-Schuyler, Herkimer, N. Y. Thorough-bred Improved Short-Horn Cattle.

MARK R. COCKRELL, near Nashville, Tenn. Saxony and Bakewell Sheep, Durham Cattle and Blood Horses.

A. B. ALLEN, Buffalo, Erie, N. Y. Berkshire and China Pigs, pure breed.

T. F. NELSON, near Milwood, Clarke county, Va. Berkshire Pigs.

B. F. JOHNSON, Rome, Oneida, N. Y. Berkshire and China Pigs.

B. C. STANTON, seven miles east of Edwardsville, Madison co. Ill. Durham Cattle, Berkshire Pigs, South-Down, Saxony, Bakewell and Merino Sheep.

WM. B. MOAKLAR, Maysville, Ky. Berkshire, Irish Grazier, Byfield and Berkshire cross, and Belmont Pigs.

DR. S. D. MARTIN, near Colbyville, Clarke co. Ky. thorough-bred and grade Durham Cattle and Woburn Pigs.

WM. WHITE and AMOS FISHER, Medway, Mass. will sell Berkshire Pigs.

ROBERT M. SCOTT, Locust Hill, Frankfort, Ky. Improved Short Horned Durham Cattle. [Three fine lithographic portraits of Mr. S.'s stock may be seen at the Cultivator office.]

C. N. BEMENT, Three Hills Farm, near Albany, N. Y. thorough bred "Improved Durham Short Horned Cattle," pure Berkshire Pigs, Neapolitan and China cross do. and South-Down Sheep.

JOHN COWLEN, Trenton, Oneida, N. Y. imported New-Leicester Bucks and Ewes.

L. D. CLIFT, Carmel, Putnam, N. Y. Lincolnshire Sheep, Bucks and Ewes.

E. CORNELL, Ithaca, Tompkins, N. Y. sells Dutton Corn and Berkshire Pigs.

JOHN LOSSING, Albany, N. Y. pure Berkshire Pigs.

W. KILBURN, Lawrenceville, Tioga, Pa. Durham and grade Cattle, and Mocho and Berkshire cross Pigs.

JOSEPH HASTINGS, Brunswick, Rensselaer, N. Y. grade Berkshire and grass breed Pigs.

H. D. GROVE, Buskirk's Bridge, Washington, N. Y. Saxony Rams and Ewes, of the pure race.

S. M. MITCHELL, Norwich, Conn. breeds and sells Stock of various choice breeds.

M. HUDSON, East-Windsor, Conn. pure improved Durham Short Horned Cattle, (Herd Book animals,) Berkshire Pigs, and New-Leicester or Bakewell Sheep.

DANIEL S. CURTIS, Canaan Centre, Columbia, N. Y. choice Bucks, Ewes and Lambs, full blooded Saxony Sheep.

George C. Thorburn.

NEW ENGLAND AGRICULTURAL WAREHOUSE and Seed Store, No. 51 and 52, North-Market-street, Boston; Joseph Breck & Co., proprietors, also publishers of the New England Farmer. We have one of the most extensive agricultural implement and seed stores in the United States. For particulars we refer to our catalogue which we send gratis, to all who apply postage paid.

Joseph Breck & Co.

HOVEY & Co.'s Seed Store and Agricultural Warehouse, No. 7, Merchants' Row, Boston, Mass., sell at wholesale and retail, all kinds of garden, grass and flower seeds, agricultural implements, books on farming and gardening. Also, fruit and ornamental trees, greenhouse plants, splendid double dahlias, bulbous roots, &c. They likewise publish the Magazine of Horticulture, a monthly periodical devoted to the cultivation of fruits, flowers and vegetables, at $3 per year.—Vol. 5th commenced Jan. 1st, 1839.

A FARM of about 90 acres is offerred for sale. It is in Watervliet, near the western bridge, on the Albany and Schenectady Rail Road. It has upon it a good barn, a small dwelling house and an apple orchard. Apply to J. Buel, Albany.

A FARMER WANTED, who can understand instructions, and will execute them. A single man, who can bring recommendations as being trusty, sober and industrious, will receive liberal wages, by applying soon, to J. Buel, Albany.

THE ORANGE FARM.—This highly improved farm situated two miles from the city, on the Philadelphia Turnpike road, is offered for rent. It contains about 300 acres of land, in the improvement of which, no expense has been spared for many years. In addition to a large quantity of barn yard manure, ashes, &c. 25,000 bushels of lime have been advantageously spread within the last four years. The improvements, consist of a plain DWELLING with ample accommodation for laborers, a costly Switzer Barn, stables for one hundred Cows, a well arranged and extensive dairy. Ice House, Steaming Room with boilers complete and every accommodetion for a Dairy Farm on the most extended scale. The House, furniture, farming utensils and horses will be let with the farm. S. W. Smith, Monument Square, Baltimore.

BONE MILL.—The subscriber has erected a mill for grinding bones for manure, at Waterford, N. Y. where those wishing to purchase may be supplied, on liberal terms.

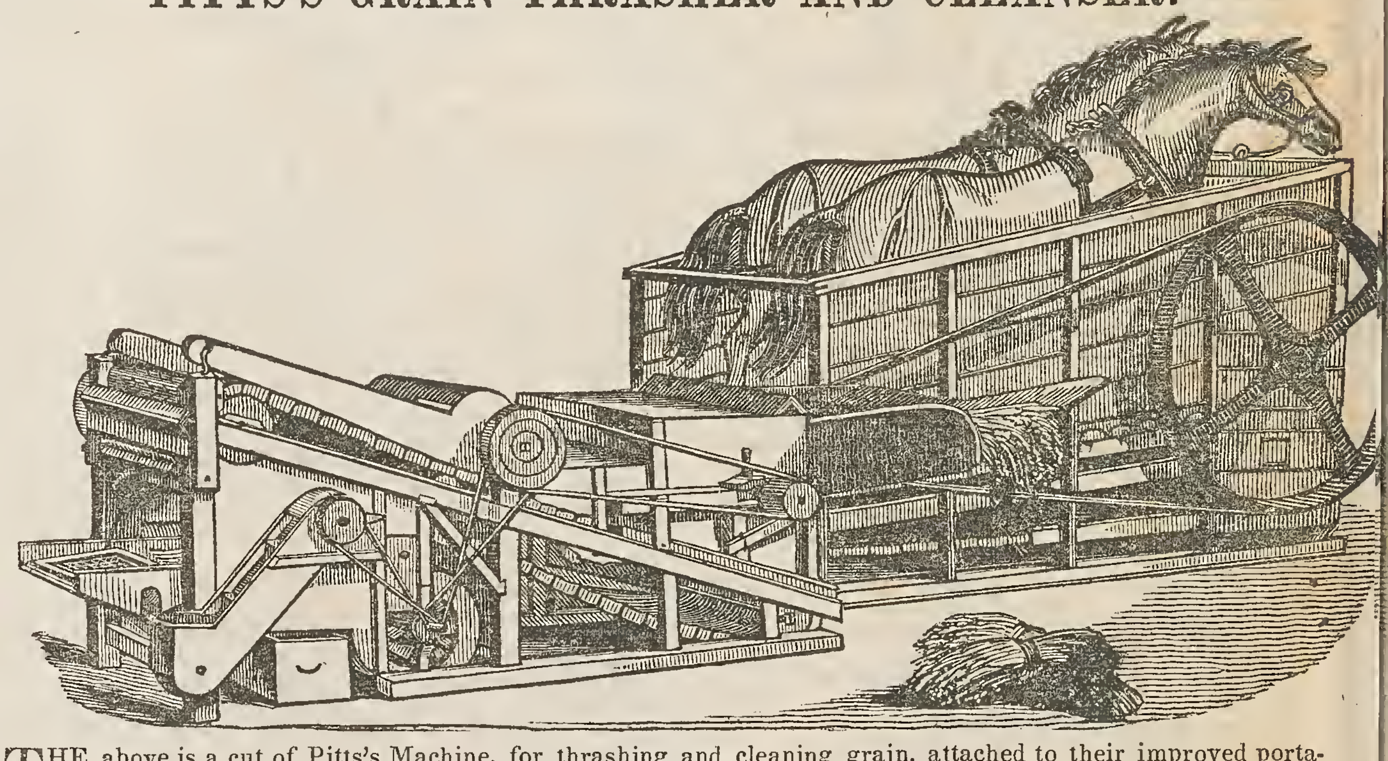
ALBANY.

PITTS'S GRAIN THRASHER AND CLEANSER.



THE above is a cut of Pitts's Machine, for thrashing and cleaning grain, attached to their improved portable two horse power. It occupies a space, 8 feet by 2 feet 4 inches. It thrashes and cleans all kinds of grain, effectually and expeditiously. Simple in its construction, it is not liable to get out of repair. The price of the machine for thrashing and cleaning grain is $150, at Albany. It may be attached to any horse power. For the character of the machine, I refer to the following, by the editor of the Maine Farmer, and also to the October No. of the Cultivator.

"Pitts's Thrasher and Separator.—Having frequently recommended this machine to the consideration of farmers, it is gratifying to find that in every trial it has sustained its good reputation. It is beyond a doubt the best apparatus for separating and cleaning grain that has as yet been invented. The experience afforded by two years almost constant use, corroborates the high recommendations which have heretofore given; and the increasing demand for it, is a proof that it performs to the entire satisfaction of all who have employed it. The grain while passing through undergoes the operation of being thrashed, separated from the straw and chaff, completely winnowed and deposited in a neat and perfectly clean condition at the other end of the machine—thus requiring no handling after it is once fed into the machine, till it is ready for the granary. I would again, with a knowledge of and full confidence in its powers, respectfully recommend it to the farmers of the United States as a most valuable and efficient labor-saving machine, having no fears that, with proper usage, it will fail to give full satisfaction to those who may purchase or use it. *Winthrop, Me. July* 5, 1838. E. Holmes."

Address the subscriber at Albany.

JOHN A. PITTS.

VALUABLE FARM FOR SALE.—The subscriber offers for sale his valuable farm, situated in the town of Brunswick, three miles east of the city of Troy, containing three hundred and thirty acres, about seventy-five of which is very valuable timber land, and the remainder under a high state of cultivation. On the premises are three good dwelling houses with other necessary out buildings. Also, a Saw-Mill contiguous to the wood lot, in good repair. The farm is well watered, and well adapted for grass or grain. Considering the quality of the land and the many advantages it possesses, it is not surpassed by any other farm in the county of Rensselaer. Any other description is considered unnecessary, as those wishing to purchase, will call and view the premises. It will be sold together, or divided to suit purchasers. Letters should be addressed to

Joseph Hastings, Troy, N. Y.

CHOICE AGRICULTURAL SEEDS.—Mangold Wurtzel, sugar beet, orange carrot, ruta baga, globe, Norfolk, Aberdeen, and other turnip seeds of the best quality constantly for sale, in large or small quantities, at the Rochester Seed Store.

Also, Rohan potatoes, Chinese tree corn, Dutton, and other choice corn, mulberry seed, silk-worms, eggs, &c. &c. Reynolds & Bateham, Rochester, N. Y.

THRESHING MACHINES.—D. A. Webster's Spring Beater Machines—having received the medal for 1837, and the only one for 1838, from the American Institute, for sale by the inventor, at 63 State-street, Albany. Also horse powers of every description.

ROCKWELL'S CORN PLANTER, which with the services of a horse and driver, will plant 20 acres in a day, may be had of Magher & Co. No. 195 Front-street, also of S. Dunn & Co. No. 193 Water-st. New-York, and of the proprietors, D. S. & F. A. Rockwell, Ridgefield, Ct.

INDEX.

☞ We have arranged under the respective heads of Household Economy—Farm Implements—Diseases of Animals—Diseases of Crops—Farmers' Garden—Meadows and Pastures—Manures and Indian Corn, &c.—whatever relates to these particularly.
